THE CIVIL ENGINEERS' BANQUET

WE do not grudge our friends the Civil Engineers their annual felicitations, nor Mr. Gladstone his congenial moral reflections. It were hardly worth while to dissect after-dinner rhetoric, however full of fallacies. But those ever-watchful teachers of mankind, the daily press, have pounced upon the speeches delivered on Wednesday week, and have made them an occasion for propounding solemnly what was spoken hilariously; and this deserves looking to.

The *Times*, of course, armed at every point, does battle valiantly for decentralisation of science, because that notion seemed to find favour with the notabilities of the evening. Mr. Hawksley, president of the Civil Engineers' Institute, in toasting Her Majesty's Ministers, complimented them on the "performance of the negative duty of letting his profession alone," adding, with unconscious satire, that what the engineers had done "they had achieved, not through, but in spite of, all Governments." These two sentiments are quite intelligible and quite true; but the conclusion of the speech, which informs us that "the Civil Engineers of this country approached the Government with perfect reliance on its purity," conveyed a needless truism; to the pure all things are pure—to pure engineers even a British Government is pure, of course. But why dwell on so obvious a fact?

Well, this put Mr. Gladstone on his mettle. At once absorbing the tribute to their inaction—rather a novel compliment to his Administration—he evolved out of it this syllogism: Engineering is science; engineering likes being left to its own devices; therefore all science should be left alone. This sort of logic is quite good enough for dinner talk, but not for breakfast reading. What may be excused to convivial excitement in a flattered guest cannot always be permitted to a journalist after an interval for reflection.

The *Times* of the 26th ult., after expatiating on the advantages of non-intervention in things in general, thus disposes of science. "If," it says, "under such conditions of Government, the State does nothing for science, it cannot be helped; nor need it be much lamented, considering how very little science stands in need of the aid. If," it goes on to say, "the Institution of Civil Engineers had been a creation of the State, fostered by State bounties, and favoured by State protection, its members would never have acquired such a position in the country as they justly boast of holding now. As it is, they have fought their way and been the founders of their own fortune; and so their president has the pleasure of telling the Prime Minister of the Kingdom that he and his constituents have been and are independent of all Governments whatever."

We give the sentence entire, because the nonsense it contains does not admit of greater condensation. Let us examine it a little. How is the engineering profession typical, as here asserted, of science? What is that profession? Simply, and without any intended offence, a profession for making money. Men put their sons into it, and have them trained, rather imperfectly in England it must be confessed, and push them forward in it, solely because the contracts, commissions, and fees, are enormous, and the chances of making a fortune pretty fair. We by no means object to this in a broad way. Other professions, held in high honour—the law, for instance—are exactly in the same category. If men possessed, or believed to be possessed, of special knowledge, find that a high price is put on that knowledge in the market, they are of course justified, as long as they perform honestly what they undertake, in demanding the highest price they can get for it. But in this respect how do they differ, not merely from lawyers, but from manufacturers and even from tradesmen? Is there any difference between making and selling so many yards of calico and so many miles of railway, between supplying customers with patent umbrellas and a patent locomotive? All are results of science, and may be products of brains other than those of the vendors. If engineers are able, by vending bridges, railways, and graving docks, to amass in a few years colossal fortunes, as we know they do, what Government help can they need more than the successful cotton lord, or the enterprising grocer, who also manage their business without external aid?

This being granted, why, asks the *Times*, should not the principle of non-intervention be applied to science? Simply because what is generally understood by the term "Science" is not a remunerative occupation. We do

not say that no one ever made money by pure science; some men have done so, as is well known, by means such as telegraphic inventions and chemical processes applied to the arts; but even these, and they are very few, have not become the millionaires, of whom not a small number are to be found amongst engineers and manufacturers. Putting aside these rare exceptions, science does not bring wealth to its cultivators. For instance, who ever made money by astronomy? What did the discovery of Neptune, the highest scientific achievement of this age, bring to Professor Adams but tardy fame? Are investigations of the properties of light, sound, gravity, magnetism, profitable pursuits? Was the inventor of a new calculus ever made rich thereby?

Shall we contend, therefore, that Government should supply the shortcomings of a scientific career, and place those who adopt it on a par pecuniarily with successful engineers? By no means. We must look a little deeper for the reason why State should aid Science. We shall find, if we examine the whole domain of Science, that there are extensive tracts which require for their vigorous cultivation very costly appliances and a long expenditure of time. Poor men cannot afford the one at all, and cannot live if they devote themselves to the other without remuneration. Hence, if such branches of science do not receive aid from without, they must languish, if not be entirely neglected. But this cannot happen without depriving the community of some addition to its material advantages which it might otherwise possess. It is notorious, not, perhaps, to all the writers of the *Times*, but to those conversant with the state of science in England, that this evil is with us in full operation with constantly increasing force. Rich men do, it is true, sometimes devote themselves to science. But no individual can do more than labour during his lifetime; and what is chiefly wanted now, in several of the most important lines of investigations, is uninterrupted continuity during immense periods of time. Will our friends, the Engineers, apply some of that "lavish liberality and unbounded enterprise," of which we have heard so much, in this direction? We suppose not. Whatever may have been the love of knowledge for its own sake which distinguished the first founders of the profession, the modern "leading engineer" knows better than to put his money and time into so unprofitable a business.

England is at this moment behind every other civilised nation in the means afforded for the cultivation of those branches of science which do not yield immediate profit. But there are men, not connected with either the Government, the *Times*, or the Civil Engineer Institute, who are alive to the peril of prolonging this neglect, and who will not rest until they have opened the eyes of their countrymen to its imminence and magnitude, at present beyond the ken of their governors and their teachers. When they have attained their object, the *Times* will proffer them its aid.

THE ERUPTION OF MOUNT VESUVIUS

THE great eruption of Mount Vesuvius, with the telegraphic accounts of which the readers of the daily papers have been familiar for the past week, is undoubtedly one of the most considerable of modern times. Whether the worst is yet over seems still uncertain while we are writing; but even if this be the case, the mass of molten lava ejected, and the amount of damage done, will appear to bear comparison with those of almost any recent eruption. One account speaks of it as the grandest eruption since 1631.

The telegraphic accounts at present received are necessarily vague, and to a certain extent conflicting, and of course it is at present impossible to do more than chronicle. Scientific results must follow afterwards.

The correspondent of the *Daily News* says, under date of Sunday afternoon:—"I have just returned from visiting the spot where the victims of the eruption perished. Streams of lava, thirty metres wide and nearly ten metres in height, were still fiery and smoking. The detonations continue as before. Part of San Sebastiano is entirely destroyed, with everything near. King Victor Emmanuel and Signor Lanza were on the spot distributing money to the sufferers. All the people fled at the time, but some were beginning to return with their goods. The shower of cinders had ceased, the sky was blue, and Mount Vesuvius, with a colossal column of smoke above it, had a grandly imposing appearance."

San Sebastiano is a village on the north-western slope of Vesuvius, almost exactly in the direction of Naples. None of the earlier eruptions extended in this direction, but a stream of lava flowed almost close to the village in one of the early eruptions of this century. The lava is here spoken of as being sixteen feet deep in places, and in other despatches San Sebastiano and the neighbouring village of Masso di Somma are spoken of as having been nearly destroyed. This stream of lava is described as having several times changed its direction, and it is probably a branch of the same which has threatened Portici and Persina (no doubt Resina, almost close to Herculaneum) near the sea-coast, and caused the abandonment of these villages.

It must be a different stream which has partially or entirely destroyed Torre del Greco, one of the beautiful villages which lie on the shores of the Bay of Naples, in a south-westerly direction from the centre of the mountain. This village, or its immediate neighbourhood, has been overwhelmed several times within the last two centuries. The statement that "the lava now reaches from Torre del Greco to within five kilometres of the eastern coast, and threatens several other communes, the inhabitants of which have, in consequence, fled from their homes," is quite unintelligible.

The effect of the eruption at Naples up to Monday night is described as follows:—"Cinders fell all last night, and they still continue to fall at this moment as I send off the present despatch. A thin rain is also falling. Near Cercola the shower of scoriæ has compelled the soldiers to build huts in which they may obtain shelter. The church of San Giordano at Cercola has been destroyed. A number of people have been surrounded by the lava close to San Sebastiano. At Ottoiano a heavy shower of enormous blocks of lava has commenced. The railway is crowded with foreigners and Neapolitans hurrying away from Naples. A fresh eruption is feared, as loud explosions were heard last night even in this city."

The fall of cinders, even at Naples, is spoken of as so heavy that the sky seemed hidden by them, and they fell

everywhere like rain. The plantations were covered with them, and people were walking with umbrellas to protect themselves from the downpour. The rain of burning scoriæ has reached as far as Scafati and Palermo. Readers of Prof. Phillips's work on Vesuvius will recollect that he throws considerable doubt on the correctness of the popular idea that Vesuvius emits *flame* during an erruption, though he thinks there are one or two authentic instances of this rare phenomenon. The accounts at present received do not throw much light on this point. One narrator states " Mount Vesuvius is displaying terrible electric phenomena, marked by flashes of lightning and vibrations of the earth ;" and another, that "flames are bursting through several craters." Other accounts speak merely of the eruption of glowing lava and smoke brightly illuminated by it, and this may readily have been mistaken for flame.

Great credit is due to Prof. Palmieri, who has remained at his post at the Observatory to watch the eruption, and from whose observations a great advance of science may be anticipated. On Monday at noon he telegraphed as follows :—" Scoriæ in great abundance have fallen in the direction of the Observatory. The instruments at the Observatory are very much disturbed. The projectiles from the volcano rise to a height of more than a kilometre. The lava has ceased to flow."

It is satisfactory to know that recent letters speak of the first reports of the loss of life as having been somewhat exaggerated. Eighty persons are now stated to be missing ; all Italians. Thirteen wounded were taken to the hospital ; of these six are dead. No English or Americ ans are reported dead or wounded.

The latest telegrams received at the moment of going to press speak of an enormous column of "fire" being visible from Naples. Explosions, accompanied by shocks like those of an earthquake, were constantly occurring. Prof. Palmieri telegraphed from the Observatory on Tuesday that the roar of the volcano had ceased. Numerous flaming projectiles continued to be launched into the air, but with less force than previously. The smoke had decreased, and the shocks, though frequent, were not of a dangerous character.

SCIENCE PRIMERS

Science Primers : " Chemistry," by Prof. Roscoe ; " Physics," by Prof. Balfour Stewart. (London : Macmillan, 1872.)

THESE little books illustrate an imperfectly accepted truth, that systematic elementary teaching is a late and not an early product of educational energy. The best headmasters of our schools have discovered the fallacy latent in our ancient belief that the ablest men are required to teach the oldest boys, and have in one or two famous cases acted on their discovery. It is easy for a young man fresh from University honours to pour his knowledge into minds which have been well prepared, and which approach more or less to the level of his own ; but to teach a class of little boys, to realise their difficulties and to appreciate their ignorance, to understand the perplexity which oppresses them in the presence of statements long since axiomatic to ourselves, requires a mature and versatile intelligence, a mind which can communicate childish knowledge as readily and as joyously as it solves recondite problems ; a combination of rare gifts with long and conscientious training.

And thus it is that the zeal for scientific teaching and the gathered scientific experience of the last fifteen years have only issued now in the books which form the subject of our notice. Scientific class-books hitherto have been either too difficult or too easy. They have been unavailable for beginners without the intervention of a practical teacher ; or in their effort to be popular and simple they have abdicated half their value as instruments of educational discipline. In these books both extremes are avoided. Every stage of their teaching is based upon experiment ; no law is enunciated till it has been proved. From first to last the student finds himself in immediate contact with Nature. His empirical knowledge of external things is systematised ; simple every-day phenomena reveal to him their principles and *rationale ;* he walks forth with a new eye to discern the meaning and the beauty of familiar sights and sounds, and with a mind upon the stretch for fresh discoveries. And, on the other hand, no previous training is essential to the teacher who adopts them as his guide. Any man, ignorant even of the first principles of chemistry and physics, yet fairly dexterous and intelligent, who will patiently master the books, and try each experiment for himself, is in a position to transmit their contents successfully and clearly. The officer may lecture to the soldiers of his regiment, the clergyman to the artisans of his parish, the national schoolmaster to the children of his school. Managers of middle schools, deterred as yet from including science in their course through lack of teachers and of text-books, will find their difficulty removed. The higher schools need no longer confine their scientific teaching to the senior forms, but may place the " Science Primer " along with the Latin grammar, in the hands of their youngest boys.

The expense of apparatus need not be considered formidable. A complete set for the course of Chemistry is set down at 5*l.* 10*s.*, for Physics at 19*l.* 3*s.* 8*d.* This last, however, includes such costly implements as the air-pump, balance, Grove's battery, and electrical machine. Leaving these to be obtained by special donation or borrowed for the occasions of their use, and deducting such further instruments and utensils as a handy man can make or convert at trifling cost, the outlay for the two courses may be bought considerably under 10*l.* And since the apparatus once established will require rare and slight renewal, one may hope that a moderate number of pupils with a moderate scale of fees would always provide this sum, more especially if the South Kensington authorities, in the presence of these manuals and of the revolution they may be expected to work, can be induced to extend the limits under which they furnish educational materials at half-price.

The names appended to the books guarantee their scientific accuracy, and their embodiment of the latest knowledge ; but from the teacher's point of view they exhibit some few statements which are not quite clear, and which may deserve reconsideration. In the Chemistry Primer (Experiment 3, p. 7) the caustic soda is left unsupported in the tube. The description is probably compelled to follow the engraving ; but most lecturers would, as is suggested in the appendix, use the U tube in such a

case. Exp. 5, p. 10, does not clearly show that the heat due to chemical union is independent of the heat caused by the lamp; while statements 6 and 7, if taken together, produce in the pupil's mind a confusion between cause and effect. In pp. 23, 25, the allusions to acid and alkali, both new names to the student, might easily be accompanied by a marginal reference to p. 65, where the terms are explained. In Exp. 17, p. 27, it is not made evident in words that the hydrogen has passed from the one bottle into the other. Exp. 22, p. 34, and Exp. 40, p. 68, would gain in value if the action of the text, as well as its result, were described, such explanation of the first experiment being actually given later on at p. 87. In Exp. 29, pp. 44, 45, the diction of the first two paragraphs is confused and confusing, and it is doubtful if any lecturer would be able to conduct Exp. 31, p. 48, so as to retain the heated filings on the magnet. In Exp. 35, p. 56, the numbers on the drawing do not tally with those of the description. The explanation of the Davy lamp, p. 57, to which further reference is made in Physics, p. 86, is, to say the least of it, incomplete: and that of the safety matches on p. 72 is quite unintelligible. The definition of an Element, p. 58, and the phrase "difficultly fusible" on p. 99, suggest purely verbal criticisms.

In the Physic Primer, p. 2, force and motion should hardly be called "qualities" of dead matter. In Exp. 13, p. 22, the "simple arrangement" for moving the horizontal piston might be indicated. In p. 23 the large and small piston are not lettered in the description. In Exp. 17, p. 26, a shrewd pupil would inquire why the upward pressure should not, from all that appears in the text, expel water from the higher aperture as strongly as the downward pressure expels it from the lower aperture. In pp. 40, 41, some allusion to the Aneroid, if not to the Hypsometer, might fairly be expected, and in p. 46 it is not easy to see why the Syphon is described if its principle is not to be explained. In p. 65 there is an allusion to "the mercury in the bulb of glass," which is, in fact, there mentioned for the first time, and is it not true that in Exp. 52, p. 105, a principle of converse action is laid down on the evidence of a specific and almost a solitary instance?

It is possible that to criticise these points as blemishes suggests stupidity to the critic; if so, his stupidity is probably typical, and the authors would be the first to wish that their explanations should be self-sufficing, even to the obtuse. In any case we tender them our hearty thanks for work which marks a stage in the advance of scientific education. Its lingering progress hitherto has been owing to the want, not of zealous champions, but of united action. The labours of its advocates are now beginning to converge. The leaders of science and the leaders of education are drawing close together—on the one side eager to impart, on the other ready to receive, advice and guidance. By the publication of these books the most serious of the obstacles which have kept them separate is removed.

W. TUCKWELL

OUR BOOK SHELF

Astronomy and Geology compared. By Lord Ormathwaite. (London: J. Murray, 1872.)

THIS little volume is the product of a thoughtful and observant mind. Its main object is to contrast the certainty of the conclusions of astronomy, the exactitude with which eclipses can be foretold, and with which other astronomical phenomena recur, and the vagueness which hangs round many geological theories, as, for instance, those connected with the age of the various strata. A large portion of the volume is directed against the theories of Mr. Darwin in natural science, and Mr. Buckle in morals, theories which the author considers, in consequence of the vagueness of geological conclusions, to rest upon insufficient data. With the general mode in which the argument is conducted, we have little fault to find. Occasionally, however, Lord Ormathwaite's zeal on behalf of orthodox theology betrays him into injustice, as when he says:—"There is one feature common to the writings of Mr. Darwin and Mr. Buckle which is to be regretted—they both of them seem to ignore, if they do not altogether deny, the existence of a First Cause. Secondary causes are always with them the only springs of motion." With this we may contrast the following sentence from the "Origin of Species":—"To my mind it accords better with what we know of *the laws impressed on matter by the Creator*, that the production and extinction of the past and present inhabitants of the world should have been due to secondary causes, like those determining the birth and death of the individual." Lord Ormathwaite pleads bodily infirmities as an excuse for any inaccuracies or mistakes in the book, and we very willingly allow the plea.

The Use and Origin of the Arrangements of Leaves in Plants. By Chauncey Wright. (American Academy of Science and Arts.)

THIS is an elaborate and ingenious attempt to apply the principles of Natural Selection, or the Survival of the Fittest, to the observed phenomena of Phyllotaxy, or the arrangement of leaves on the stems in plants. Stating in the outset very clearly the distinction between this theory, according to which every organ, and every arrangement of organs, must be of some practical (though possibly undiscovered) utility to the plant, and that of "types," which requires no such hypothesis, Dr. Wright proceeds to investigate how the origin of the phenomena under investigation can be accounted for on the former theory. It must be assumed in the outset that the two principal modes of the arrangement of foliar organs, of which all others are modifications, the spiral and the verticillate, are modifications of a single original type. Investigating the actual arrangements on mathematical principles, he finds that the various angular distances of leaves on the stem are resolvable into the general form of the continued fraction

$$\cfrac{1}{a+\cfrac{1}{1+\cfrac{1}{1+\text{\&c.},}}}$$

in which a may have the values 1, 2, 3, or 4. The actual fractions thus resulting are when

$$\begin{array}{lcl}
a = 1 & . \quad . & \frac{1}{2}\ \frac{2}{3}\ \frac{3}{5}\ \frac{5}{8}\ \frac{8}{13}, \text{\&c.} \\
a = 2 & . \quad . & \frac{1}{2}\ \frac{1}{3}\ \frac{2}{5}\ \frac{3}{8}\ \frac{5}{13}, \text{\&c.} \\
a = 3 & . \quad . & \frac{1}{3}\ \frac{1}{4}\ \frac{2}{7}\ \frac{3}{11}\ \frac{5}{18}, \text{\&c.} \\
a = 4 & . \quad . & \frac{1}{4}\ \frac{1}{5}\ \frac{2}{9}\ \frac{3}{14}\ \frac{5}{23}, \text{\&c.}
\end{array}$$

each fraction being obtained by adding together the numerators and denominators in the two preceding fractions. Practically it is found, however, that certain only of these fractions occur in nature, while of those that are found some are much more frequent than others. The approximate ultimate value (k) of this continued fraction, when $a = 1$, is 0·6180, k possessing the property that any power is equal to the difference between the two next lowest powers, or $k^n = k^{n-2} - k^{n-1}$. On this peculiar arithmetical property of k depends the geometrical one of the spiral arrangement which it represents, namely, that such an arrangement would effect the most thorough and rapid

distribution of leaves around the stem. The latter part of this valuable paper consists of an attempt to show that the modes of phyllotaxy which result from the use of the different forms of the fraction are either directly serviceable to the plant by affording the best distribution, either for absorbing the sap from the roots or for exposing it to the action of air and light, or have been so at some period of the ancestry of the plant, when its structure was of a simpler character. The typical or unique angle of the theory of phyllotaxy the author regards to be the goal towards which the special forms tend, by the action of the principle of natural selection, rather than as the origin of the spiral arrangements. A. W. B.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Law of Total Radiation

In NATURE for April 25 Captain Ericsson attacks the calculation of Pouillet as to the sun's temperature, as being founded on an erroneous law of radiation. Had he contented himself with saying that the extension of Dulong and Petit's law so far beyond its experimental foundation to temperatures approaching that of the sun was "mere theory," and inconsistent with his own experiments, his position might have been impregnable. But not satisfied with this, he goes on to question the applicability of Dulong's law even below the boiling point of mercury, and asserts that Newton's law is much nearer the truth. The only objection that he gives to the method of the French experimenters is that they erroneously confuse the *surface* temperature of their thermometers with the average temperature of the contained mercury. The observed radiation is really due to the first, though attributed to the second. Now, without asserting that the objection is entirely without force, I submit that, if Newton's be the real law of radiation, it is impossible in this way to account for the observations.

In the first place, if the rate of cooling for a body at a variable temperature t, surrounded by another at a fixed temperature t_0, be proportional to $t - t_0$, it follows from the theory of exchange (than which there are few things better established) that the radiation between two bodies at any temperatures t, t', is proportional to $t - t'$. The rate of cooling of the thermometer contained in an enclosure would thus depend only on the *excess* of temperature, in flat contradiction to Dulong's observations. Nor would this result be altered, even though the material of the thermometer were so badly conducting in relation to its size as to allow the surface temperature to fall considerably below that of the interior. Whatever may be the relative temperatures after a given time of a system composed of a conducting mass, originally at a uniform temperature of 100°, surrounded by an enclosure maintained at 0°, the same after the same time will be the differential temperatures of the corresponding parts of another similar system, whose interior mass had originally a uniform temperature of 200°, with a case maintained at 100°. In fact, according to Newton's law, and with a constant conductivity, the superposition of any constant temperature over the whole system alters none of the conditions.

If it be objected that in the interior of a thermometer heat is distributed, not merely by conduction, but is convected by currents in the mercury, even this, I believe, will make no difference. The convection currents are a consequence of differences of density, and these are approximately proportional to the differences of temperature. The addition of a constant temperature to the whole alters nothing.

Judging from the evidence at present before us, it is impossible to avoid the conclusion that within the limits of Dulong's experiments Newton's law of cooling cannot be even approximately true. If Capt. Ericsson, by bringing forward fresh experiments, and by proving the fallacy of old ones, can establish the truth of Newton's law, he will lay Science under a great obligation. Speaking as a mathematician, I could even wish him success.

With regard to high temperatures it seems certain that Dulong and Petit's law fails; for it is impossible to believe that the sun is no hotter than 1,500° Cent., at least if the estimates hitherto made of terrestrial temperatures are substantially correct. It must be remembered, however, that according to Fizeau the sun is only about $2\frac{1}{2}$ times brighter than the electric arc, which does not even imply a higher temperature; because, while the sun must give us nearly the whole radiation due to his temperature, the electric arc is probably transparent.

J. W. STRUTT

Terling Place, Witham, April 29

Solar Halo

THIS morning, at 9.20, I observed a strongly-marked halo round the sun. Roughly extemporising a sextant with a post-card and paper-vector, I took three observations on the semi-diameter, and found the mean to be 22°·6. So I conclude this to be the ice-halo, whose deviation is 23°, being formed of hexagonal crystals. Two facts render the halo noteworthy—(1) the morning (after a heavy gale from the south) was exceptionally warm; (2) the halo exhibited the extreme colours in the proper order. I am told halos do not exhibit colours. Surely they ought to; and if not, why not? Let some of your readers answer me this. The halo was visible till nearly 10 o'clock.

Bournemouth, April 26 C. M. INGLEBY

Help us to save our Birds

ALL praise be given to those who have made a stand for the preservation of British birds. With a spirit of patience they have had to encounter the crass prejudice that sometimes saturates even the rural mind, and to prove that if the small bird takes its toll from, it also greatly assists in preserving the store of, the farmer. They have had to combat the sporting instincts of the excited townsman, so joyous with his escape from the smoky labyrinths of his brick-built prison that even a feathered shuttlecock would almost seem like game. Last and greatest feat, they have had to question the right to worship the national idol—gain, and to teach people, that even if, by the wholesale slaughter of feathered tribes, some persons scraped up gold, still that occupation, however praiseworthy, was against the general good. Truth at last dawned on the mind of the people, and so Parliament shielded, amongst other fowl, the pretty kittiwake from destruction, and preserved fashionable women from one more barbarism.

Those who have thus worked to educate the public need not rest on their oars for lack of employment, let them look farther afield, let them fearlessly step across national boundaries, and lend their strength to assist in arresting the impending destruction of many species of the most beautiful and interesting orders of animated nature in any quarter of the globe.

New Zealand, so long left by science to slumber on the calm bosom of the Pacific, has disclosed, amongst her birds, forms that have surprised the naturalist as much as they have excited the speculation of the philosopher. The remains of birds, of orders other than the gigantic Struthiones, giving us hints about strange *lost* forms of animal life that have lingered in these islands, perchance, almost to our own times, are now and then exhumed from the hidden shores of swamp and morass. We raise a cry for help in behalf of the mass of birds that yet remain *near* us (we had almost said *with* us), in the hope that the attention of naturalists in Europe may be called to the peril of extermination that hangs over many interesting indigenous species. For the preservation of our birds we require some assistance from abroad, our time is so crowded with occupations of many kinds, that without some pressure from without, little attention would be likely to be paid to the subject. This is said not without reason, not without some experience; in 1868, in Parliament, the writer tried to secure the conservation of our magnificent forests, a resolution was passed by the House to that effect, official inquiries were made;—*cui bono?* Our forests are now being damaged and destroyed, where not protected by climate, in so ruthless a manner, that no further evidence is needed to prove our wasteful style of settlement. Will not some one having authority in such matters speak a word in due season for our birds? I believe nearly every living species that we number could be preserved with proper care. If that is a fact, is it not interesting enough to naturalists to induce them to stimulate us to efforts more likely to give better results than our present legal enactments?

We encourage planting, the labour and capital therein expended may yield returns after the lapse of generations; we, at the same time, allow timber, the growth of ages, to be swept by fire by any one who owns a box of matches, and looks on firing as the best means of subduing the wilderness. We import with great difficulty insectivorous birds, and allow the Apteryginæ and other insectivorous genera to be destroyed without mercy.

Fearing to occupy too much space, I will only glance at our worst raptorials from which our birds suffer. First, the *bonâ fide* settler in his "new chum" phase, before "he has eaten his tutu" (as we say); next, the digger, who kills kivi, kallapo, kalla, and pigeon, without any respect to season; his dog, like that of the settler, being a more fatal enemy to birds than himself. Lastly, the collector, the provider of rarities for museums, &c. There is no fence month with him; if spring or summer plumage is interesting, so also is that of winter; eggs, young, the adult, alike he preys on all. He is heedless of the Mosaic promise; he cares not to have his days prolonged, so that he gets good specimens.

Could we be persuaded to try and avert what will some day be a great reproach to this country, the destruction of so many species of our feathered tribe, D'Urville's Island might be found most useful. Wingless species, and birds of feeble powers of flight, might there find a refuge for some of their representatives. Resolution Island might be placed under tapu from molestation by dog and gun. THOMAS H. POTTS

Ohinitahi, New Zealand, February 2

The State and Science

FROM the position taken by Mr. Gladstone with regard to the Dublin University Bill, from Mr. Lowe's speech at Halifax, and from other indications, it would appear to be the policy of the Government, not to render accessible to all, without sectarian distinction, the professorships and other endowments of the Universities, and to assign to modern culture a fair share thereof, but to abolish all such endowments, and to withdraw all State aid from both literature and science. In favour of such a policy it has been urged not only that it is in accordance with sound political economy to leave every pursuit to seek for itself its own reward, but also that the system of endowment and artificial aid has proved a signal failure. Now, if by this last argument it is meant that the large rewards which have been given for classical knowledge and for mathematical attainments have not been productive of numerous Bentleys, Porsons, and Newtons, the truth and validity of the argument must be admitted. The rewarding of mere acquired knowledge was little likely to show its results in original work. The capacity for acquisition, literary, mathematical, or scientific, is a very different thing from the power of original production, or of extending the boundaries of human knowledge. Probably in some cases the latent spark of genius has even been stifled and smothered by the load of "cram" necessarily superimposed to meet the requirements of exacting examiners. It would be, however, I think, a mistake not to allow some considerable reward to more exact knowledge. But it is with regard to original work and the proved capacity for doing it that external encouragement and reward is absolutely necessary. Such work, in most departments of literature and science, cannot possibly, in a commercial sense, pay. It is this work, however, which confers especial honour and advantage on the State. Therefore it is in accordance alike with justice and sound policy that the doing of such work should be munificently encouraged and rewarded by the State. Such a policy might be reasonably expected to issue in results very different from those which have attended the endowment of "cram." Previous failure cannot be objected, for the attempt can scarcely be said to have ever been made. It behoves, therefore, literary and scientific men to look to it that, in any redistribution of the University or other endowments, the true interests of both science and literature—and especially the encouragement and reward of original research—are duly regarded by the Government. But a certain superficial political economy may object that such a policy would be of dangerous tendency, inasmuch as it would recognise the existence of the State as a unity, which, being honoured and benefited, should encourage and reward. The man of original thought and the discoverer of Nature's secrets must be left, each for himself, to seek such recompense as he can in the ordinary market. Sir Isaac Newton would not be rewarded by the present Government with the Mastership of the Mint. They have abolished that office. No, they would guard him in his enjoyment of the copyright of the "Principia!" Such, it would seem, according to Messrs. Lowe and Gladstone, is the dictate of common sense, of justice, and of the "sound political economy" of ADAM SMITH

Brilliant Meteor

I NOTICED in your number for last week the account of a brilliant meteor, observed in Cumberland on April 19. Now I had reported to me a very similar meteor at nearly the same time (about 8.40 P.M.), an account of which I forwarded, with my other results of the night's watch, to Mr. A. S. Herschel, who would gladly receive any further report of the same; unfortunately, I have not that number of NATURE at hand, and therefore cannot make a personal application to your correspondent. On the same evening, about 10.7, I myself saw an exceedingly brilliant meteor, which fell to a point just S. of Vega. It is curious that both of these come from the radiant situated about R.A. 155, D + 47, or rather from one of the group of radiants there situated, M_8 of Heis, 56 and 52 of Schiaparelli. It would be an interesting point of investigation whether the meteors from that radiant are of peculiar brightness.

EXPERIMENTAL ILLUSTRATIONS OF MUSICAL TONE

REFERENCE was recently made in these columns to an educational lecture on "Musical Tone," delivered by me on March 14, at the Taunton College School. Among the experiments, several were specially arranged in connection with this lecture, and these I should be glad to put on record as simple and inexpensive means of illustrating important points.

For the purpose of displaying the relation between the "quality" of musical tones and the kind of vibration producing them, a series of magic-lantern slides were shown. These were prepared in the ordinary way, being smoked glass plates on which vibration-lines were traced by points attached to tuning-forks, piano-wires, &c. Each tone being sounded as its vibration-line was shown, the audience was enabled to appreciate clearly the difference between the simple tone of the tuning-fork and the clangs of a stringed instrument, played on musically and also made to shriek and rasp. For an extreme illustration, to show the relation of an irregularly discordant clang to an irregularly bent and jagged vibration-line, a toy popularly known as a "Bismark's Whistle" was made, larger than the usual size. It consisted of a tin-plate canister, near the centre of the bottom of which a piece of gut, knotted at the end, was passed through a small hole. Well-resined fingers drawn with a tight grip along the gut caused this infernal machine to emit a hideous sound, the vibration-line of which was shown as taken off on the smoked glass from a pointed wire soldered to the bottom of the canister.

The pictorial representation of a beat is of course indispensable to explain Helmholtz's theory of harmony and dissonance. As, however, neither the plan used by Prof. Helmholtz of taking off the beats of two organ pipes by means of a vibrating membrane, nor the splendid arrangement of Lissajou's method employed by Prof. Tyndall, were readily available, I found it necessary to contrive a simpler and coarser method. Accordingly, two stout piano-wires were stretched side by side on a board about three inches apart, and connected near the middle by a bent yoke of thinner wire, terminating upwards in a point. The two wires being tuned so as to give beats at a convenient rate, the alternate phases of addition and subtraction of the vibrations of the two wires, corresponding to the beats, were well

shown by the central pointer, from which pictures of the beats were taken off on the smoked glass, forming admirable slides.

Mr. R. Knight, of Wellington, who superintended the making of the apparatus, devised a neat arrangement for showing the lengths of resonant tubes (See Tyndall, Lecture V.). It consists of a 4-ft. length of 3-inch zinc tube mounted upright on a foot and nearly filled with water, so as to form a cistern in which a 2-in. tube is raised and lowered, answering at the proper height with powerful resonance to a large tuning-fork. This apparatus will, I expect, come into use in future as the most convenient means of demonstrating the principle of lengths of organ-pipes. When the instrument is used for class purposes, it may be recommended that the tube be graduated to quarters of an inch, so that the pupils may be practised in calculating the wave-length, and thence the pitch, of any tuning-fork tested by the resonant tube. Further, with reference to the theory of musical pipes, it may be worth while to mention that an 8-ft. length of ¾ in. iron gas tube serves well to produce the overtones of open pipes. It is best to fit some kind of trumpet mouth-piece at one end, by means of which the most elementary musical scale, that of simple trumpet-music, may be effectively given.

No ready way being found of displaying Sir. C. Wheatstone's kaleidophone experiments on a large scale, they were shown afterwards as table experiments. Since then, however, a Chinese joss-stick has supplied the means of showing to an audience the path of the end of a vibrating rod. A piece of the lighted stick attached to the end of an umbrella rib shows beautifully convoluted figures several inches across. Any other means of attaching a bright permanent spark may of course be used, and the plan serves also to show the path of a point on a long vibrating wire. The experiment of waving a large tuning-fork to and fro while in vibration, which Mr. Sedley Taylor described in NATURE, vol. v. p. 321, had also been noticed by us. For want of means of making the result visible at a distance, it was not shown in the lecture. An inch of lighted joss-stick, however, fixed transversely near the end of one leg, shows well the contrast between the line of light traced by waving the fork in its quiescent state, and the series of dots of light into which this line is resolved when the fork is waved or swung while in vibration, its counteracting movements bringing it to momentary rest.

E. B. TYLOR

*ON THE SULPHUROUS IMPURITY IN COAL GAS**

THE lecturer commenced by stating the origin of the sulphurous impurity in coal gas to be the iron pyrites which is contained in coal, and that in the manufacture of gas, when the coal is strongly heated, the sulphur of the iron pyrites not only combines with hydrogen to form the gaseous sulphuretted hydrogen, but also with carbon, to form the very volatile liquid bisulphide of carbon. Little need be said of the desirability of removing the sulphur from coal gas, for in many of our large libraries, such as that of the Athenæum Club, the injurious effect of the sulphurous and sulphuric acids produced by the combustion of gas containing sulphur, seems to be plainly manifest, more especially on the leather binding of the books. The gas, after leaving the retorts in which the coal is heated, is cooled down, and passed through towers filled with coke, over which water is kept trickling. By these means a considerable proportion of the sulphur is removed in the form of sulphide of ammonium. It was shown by experiment that this washing with water could only be employed to a limited extent; as by excessive "scrubbing," as it is technically termed, the gas is greatly deteriorated as to its illuminating power. The sulphuretted hydrogen remaining in the crude gas is easily removed; but the removal of the bisulphide of carbon is attended with so many difficulties that up to the present time no satisfactory process has been devised to effect this purpose. The lecturer exhibited strikingly the two methods used for the removal of the sulphuretted hydrogen, one by passing the gas over lime, and the second by passing the gas over oxide of iron, and stated that it is comparatively rare to find any of this impurity in the gas as supplied to consumers. Up to the present time no process is used for the removal of the bisulphide of carbon. Mr. Harcourt has, however, found that by heating a mixture of bisulphide of carbon vapour and hydrogen to redness, the former is decomposed into sulphuretted hydrogen. It will be thus seen that the removal of the bisulphide of carbon from coal gas is rendered possible, for by simply heating the gas to redness the sulphur combines as before with hydrogen to form sulphuretted hydrogen, which can be easily removed by passing through a purifier containing oxide of iron. In this way, by passing coal gas, which contained 30 grains of sulphur in 100 cubic feet, through a red hot tube, and then through an iron purifier, the sulphur was reduced to about 5 or 6 grains in 100 cubic feet. It might be imagined that the passage of coal gas through a red hot tube would deteriorate its quality; but Mr. Harcourt's experiments show that the contrary is the case, for by passing gas of 14·91 candles rapidly through a tube heated to moderate redness, the illuminating power was found to be 15·1 candles, and after passing through a tube heated to bright redness, its illuminating power was increased to 16·66 candles. A parallel case to this is seen when marsh gas is decomposed into hydrogen and carbon by a series of electric sparks, the gas which is obtained occupies almost twice the original volume of the gas, but possesses a far greater illuminating power than that of the original marsh gas, owing to the presence of a small quantity of acetylene or some such body. It will be seen that these experiments offer what certainly seems to be a feasible process for the great reduction of the amount of sulphur contained in coal gas.

* Abstract of a Lecture delivered at the Royal Institution on February 19, by A. Vernon Harcourt, F.R.S.

PROPOSED OBSERVATORY IN NEW ZEALAND

ON Dec. 16, 1850, the first ship-load of emigrants, under the auspices of the Canterbury Association, landed at Port Lyttelton and commenced the foundation of the present province of Canterbury. On Dec. 16, 1871, the settlement attained its twenty-first year, and it was felt by a large number of gentlemen here that it would be well to celebrate the majority of the province by some permanent memorial. A meeting was held on that day, attended by a number of the most influential residents; and it was unanimously resolved to form an association for the establishment of an astronomical observatory near Christchurch. It was remarked by several speakers that this province possesses considerable advantages for such an institution. Between the ocean on the east and the great range of the Southern Alps on the west, there stretches an expanse of unbroken plain more than 100 miles in length and 50 in breadth. The remarkable clearness of the atmosphere, joined to this large extent of level land, renders it possible to observe a much larger area of the heavens than is usually the case. The meeting fully endorsed the remarks of the promoters of

the movement; a temporary committee was formed, and lists of subscribers and donors were at once commenced.

By a curious coincidence, the telegram announcing the formation of the Society no sooner came under the notice of the Colonial Government, than they informed the committee that they had, a short time before, received a communication from the Imperial authorities on the subject. The Astronomer Royal had intimated his desire to form a station in New Zealand for the observation of the Transit of Venus in 1874, and had recommended Canterbury as suitable for the purpose. This announcement was naturally most encouraging to the committee; steps were immediately taken by them to communicate, through His Excellency the Governor, with the Imperial Government. The Governor and his advisers have informed the Society that they cordially approve of its object, and will assist it as far as possible.

The Provincial Council of Canterbury was in session a few days later. Petitions were presented to it by the Society, praying for a grant of 1,000*l.* towards buildings, &c., and 5,000 acres of the waste lands of the province as an endowment towards the permanent maintenance of the Observatory. The Council, by a majority of twenty-five to eleven, voted the sum of 1,000*l.*, and 200*l.* for a site; but they declined at present to grant the endowment in land. The money grant of 1,200*l.* was likewise made conditional on the agreement of the Colonial Government to undertake the maintenance of the Institution. The great interest taken in the movement by His Excellency the Governor and his Ministers leads the Society to hope that a satisfactory arrangement may be made, so that before this time next year we may be placed in a position actually to commence operations.

Although only a month has elapsed since the first meeting, the Society has been warmly supported in this province. Additional subscriptions are received every day, and since January 22, when the temporary committee presented their report, the number of annual members has been increased to nearly 200.

I enclose the report of the temporary committee, which details the work actually done by them so far. You will see that the committee have attempted to commence the practical work of founding the Society by asking the Astronomer Royal to send out a gentleman to advise as to a proper site and other initiatory work. It is our hope that our object may receive a cordial concurrence from scientific men at home. We desire to co-operate with similar institutions in the old world by performing work which may not only be of practical use to our community here, but may, if possible, add something, however small, to the results of labours of older workers in the field of science. We trust that even one of England's youngest daughters may be of some assistance in this respect to her more favoured sisters.

W. M. MASKELL, Hon. Sec.
Observatory Society of Canterbury.

A NEW MODE OF TAKING CASTS

MR. BOYD DAWKINS, F.R.S., has recently exhibited to the Manchester Philosophical Society a number of casts in plaster of Paris of various objects of natural history, and explained the process by which any one can make them for himself. The material of the mould is artists' modelling wax, which is a composition akin to that which is used by dentists. And as it becomes soft and plastic by the application of heat, though in a cold state it is perfectly rigid, it may be applied to the most delicate object without injury. As it takes the most minute markings and striations of the original to which it is applied, the microscopic structure of the surface of the original is faithfully reproduced in the cast. The method is briefly this:—1. Cover the object to be cast with a thin powder of steatite or French chalk, which prevents the adhesion of the wax. 2. After the wax has become soft either from immersion in warm water or from exposure to the direct heat of the fire, apply it to the original, being careful to press it into the little cavities. Then carefully cut off the edges of the wax all round, if the under cutting of the object necessitates the mould being in two or more pieces, and let the wax cool with the object in it, until it be sufficiently hard to bear the repetition of the operation on the uncovered portion of the object. The steatite prevents the one piece of the mould sticking to the other. The original ought to be taken out of the mould before the latter becomes perfectly cold and rigid, as in that case it is very difficult to extract. 3. Then pour in plaster of Paris, after having wetted the moulds to prevent bubbles of air lurking in the small interstices, and if the mould be in two pieces, it is generally convenient to fill them with plaster separately before putting them together. 4. Then dry the plaster casts either wholly or partially. 5. Paint the casts in water colours, which must be *fainter* than those of the original, because the next process adds to their intensity. The delicate shades of colour in the original will be marked in the cast by the different quantity of the same colour which is taken up by the different textures of the cast. 6. After drying the cast, steep it in hard paraffin. The ordinary paraffin candles, which can be obtained from any grocer, will serve the purpose. 7. Cool, and polish the cast by hand with steatite. The result of this process is far better than that obtained by any other. The whole operation is very simple, and promises to afford a means of comparison of natural history specimens in different countries, which has long been felt to be a scientific need. It has been already introduced into America and India by Mr. Dawkins, and samples of the casts are to be seen in the British Museum, as well as in that of the Geological Survey, and of Oxford, and of the Queen's College. Casts of type specimens may be multiplied to any extent at a small cost of time and money, and are as good as the original for purposes of comparison, and almost as hard as any fossil.

The modelling wax can be purchased from Messrs. Lechertier, Barbe, & Co., artists'-colourmen, Regent Street.

THE NEBULA ROUND η ARGUS

A PAPER, accompanied by five drawings, has recently been read to the Royal Society of Victoria by Mr. McGeorge, on the star η Argûs and the great nebula near it, from which we select a few statements which appear to establish the occurrence of sensible changes in that region of the sky. After noticing the value of Sir John Herschel's drawing and description of the nebula, Mr. McGeorge remarks that from 1838 to 1869 no trustworthy observations of the nebula could be made, for want of instruments of sufficient power; though Mr. Tebbutt and others have contributed valuable information about η itself. A single glance is sufficient to show the complete inapplicability of Herschel's drawing or description to the present appearance of the nebula in the Great Melbourne Telescope. This, however, might be attributed to the great power of the instrument, whose light exceeds that of the 20-ft. reflector as much as that surpassed the other telescopes with which the nebula has been observed.

But the changes indicated in the present paper cannot be so explained, for they have nearly all been traced in the *Great Melbourne Telescope itself*, and are described in detail, with reference to drawings and observing notes. A few may be mentioned here.

η, which Herschel saw involved in dense nebula, was in April 1869 seen on the bare sky, the nebula having disappeared for some distance around it. Drawing No. 1, which accompanied the paper and which is here reproduced,

then made, shows that the southern loop of Herschel's Lemniscate had bulged out into the vacuity, forming an isthmus which trended north and joined the northern loop. The *second* drawing, January 1870, shows that within six months this isthmus had detached itself from the north side of the Lemniscate, through 90″, to form a broader peninsula. The third drawing, April 1870, shows the outline of a gulf or cleft, commencing at H 634. This

PRECEDING

NORTH

SOUTH

FOLLOWING

star is one of the "landmarks" described in 1838 as being "near the margin of the Lemniscate." It is now in mid-channel. These three drawings were made by Mr. Le Seur. No. 4 was made by Mr. McGeorge at the close of December in the same year. It confirms the existence of the Gulf; another of the "landmarks," H 616, is now nearly clear of nebula. A promontory shown in No. 2 has detached itself to form an island of nebula with a starry nucleus. This and the neighbouring outline of the Lemniscate have the same hard definite outline given by

PRECEDING

NORTH

SOUTH

FOLLOWING

Herschel; at one part, however, the outline seems encroaching upon the Lemniscate, and leaving an oval patch of thinner nebula; southward the outline seems to be curdling and breaking up. A fifth drawing, which is also here given, was made in June 1871, which amongst other changes shows that the island has shifted; the nucleus is now detached from it, and proves to be a triple star.

Mr. McGeorge finds, as Lord Rosse did, that high powers on a good night bring out details of nebula invisible with lower powers. On one occasion he speaks of using 1,300, whose definition, he says, "was magnificent for an hour." He notices a sort of stereoscopic effect which, particularly with the high powers, makes the Lemniscate look "like a huge snowy cave with uneven woolly sides."

In December 1869 the spectrum of η Argûs showed bright lines; but in January 1871 there was no trace of them; but Mr. McGeorge thought that with a wide slit he detected absorption bands in the position of the usual nebular lines. Distinct nebulosity was then visible round the star, most condensed near it, chiefly in the direction of the Lemniscate.

It is perhaps unnecessary to remark that Mr. McGeorge has seen nothing in the way of coloured stars at all to be likened to κ Crucis; one or two are reddish.

It is the intention of the Melbourne astronomers to pursue unremittingly the study of this nebula, which seems already to have given them such remarkable results. But it is evidently a most laborious task which they have imposed on themselves. At present they are confining their attention to the vicinity of the Lemniscate, but even there the field of labour is immense, for already they have noticed three times as many stars as were seen by Herschel.

They have with them the best wishes and sympathy of all astronomers. T. R. ROBINSON

Armagh, April 21

BRITTANY DOLMENS AND LINES

MR. JAMES FERGUSSON, in his interesting volume on "Rude Stone Monuments in all Countries,"* which will doubtless become a text-book on that section of archæology which pertains to Megalithic structures, has made one or two unintentional misstatements, discrepancies, or errata, which perhaps he will allow me to correct through your columns, in hopes that they may be in time for the second edition, which is probably called for, if not accomplished. I will state them as briefly as possible.

I. Carnac (p. 349): "No stone in the neighbourhood of Carnac is hewn or even fashioned beyond splitting, and *no sculptures of any class have been traced*" (italics are mine). Will Mr. Fergusson forgive me if I point out that the tumulus of Kercado, situate in the grounds of the Chateau of the same name, and marked in the map of the neighbourhood of Carnac given in his volume Fig. 135 as "Kercadio Tums. 2" has well marked sculpture on at least three of its stones, one of the figures, viz. that on the under-surface of the capstone, being evidently of the same type as the *Hatchet (?)* in the roof of Dol-au-Marchand or Table de César, see Fig. 149 (where by-the-bye I never could make out the so-called plume), and is identical with one in Bé-er-groah (Locmariaker). This tumulus, or dolmen-mound, as I prefer to call it, is much nearer to the lines of Kermario and Kerlescant than Mont S. Michel is to the lines of Menec. I should add that M. René Galles figures two of the sculptured stones, but not the hatchet.

But this is not the sole example of sculptured stones in the neighbourhood of the Carnac amorpholiths. In the curiously arranged dolmens called the "Grottes de Kerozille," are distinct traces of former sculpture (in which, if I mistake not, some traces of some coloured pigment have been discovered by W. Lukis), of which M. Galles gives but imperfect representations. Doubtless all the stones were covered with similar ornamentation, which has disappeared from the weathering of the stone surface. The "Grottes de Kerozille" are situate to the north of Menec, about two miles distance, marked Dols. 11 and 12 in MM. Blair and Ronald's map as given by Fergusson. There are in reality three dolmens, the centre one at right

* *Vide* NATURE, Vol. v. p. 386.

angles to the other two, and almost connecting them with traces of a fourth; all have been covered under one mound. In "Les Grottes de Plouharnel," where the gold ornaments were found, are traces of rude sculpture. I need hardly add that none of these archaic markings are in relief, as is the case with the celts shown in Sir Henry Dryden's drawing from Gavr' Innis, Fig. 152. Flowing labyrinthical lines seem characteristic of the Kerozille dolmen-mound, whilst straighter lines forming network are peculiar to Kercado. On the summit of the neighbouring dolmen of Runusto are some cup-markings which bear a very fair resemblance to the constellation of the Great Bear together with the Pole Star. The *tolmen entrances* in the long barrow close to and north of the Kerlescant alignments, one of which is figured (*vide* Fig. 139), were doubtless fashioned artificially, at least I think Mr. W. Lukis, who has described them, will bear me out in this assertion. It is indeed a monstrous pity that the Société Polymathique du Morbihan should have permitted such an interesting structure to be destroyed.

I should not have taken the trouble of bringing the foregoing notes to the notice of the public in your pages had it not been for the great stress laid by Mr. Fergusson on the fact of the marked distinction made by him between

FIG. 1.—ALIGNMENTS OF AMORPHOLITHS, KERMARIO.
From Sketch by Capt. S. P. Oliver, R.A.

the Locmariaker monuments and those in the neighbourhood of Carnac, the latter of which he asserts *cannot* be dissociated from the Carnac alignments.

In a communication addressed to the Anthropological Institute, I endeavoured lately to prove that the hewn and sculptured stones of Locmariaker were of a different type from the rough and shapeless blocks of Carnac, which latter I ventured to distinguish by the name of "Amorpholiths," and for that very reason disassociated the dolmen-mounds, such as Kerlescant, Kercado, and Mont S. Michel, from the lines and avenues, excepting the *unchambered* barrow at the western extremity of the Kerlescant lines which appear to lead up to it. An endeavour to classify the Dolmen-mounds of Brittany is appended herewith.

II. As to the fallen menhir, which Fergusson asserts *belongs to* the dolmen named *Dol-au-Marchand*, and which, in his idea, was in reality two *obelisks* and not one; the accompanying trustworthy plans and elevation of the renowned monolith ought to prove to the most sceptical that the remains in question are without doubt fragments of one huge monolith, which was, moreover, artificially fashioned, and, possibly, originally actually polished.

I confess that I was disappointed when I found that the Carnac lines were summarily disposed of by Fer-

FIG. 2.—PORTION OF THE KERMARIO ALIGNMENTS FROM THE NORTH.
From Sketch by Capt. S. P. Oliver, R.A.

gusson in nine pages, whilst over fifty are devoted to Avebury and Stonehenge! (although he terms the former the most remarkable group of megalithic remains, not only in France, but perhaps in the whole world); also at not finding a single illustration of the said lines beyond the maps, which, valuable as they are, give no idea to the reader who has not actually visited the spot, of the size and style of the amorpholiths. I enclose a view of the Kermario avenues, looking west, premising that the more distant stones are the largest, and that they decrease in size towards the foreground, the perspective diminishing the effect of this difference in the size of the stones.

III. Why does the celebrated dolmen (Fig. 126) of *Kercouno* appear under the name of *Krukenho?* Louis Galles gives the etymology of this place as "*village du souvenir.*"

IV. Not much faith can be placed in Mahé's (not Malé) representation of an *ideal* demi-dolmen, Fig. 129. In his "*Antiquités du Morbihan*," it is ideal, and has no local habitation or name.

V. P. 349. The *Veneti* are styled *Venetes*, and p. 356 *fibrolite* * is printed *tribolite*—printer's errors! With re-

* La fibrolite est un silicate anhydre d'alumine; elle doit par ses caractères être rattachée à la sillimanite (des Cloizeaux). Couleur blanc-laiteuse souvent jaunâtre et marbrée de veines et de tâches grises ou couleur de rouille. A peu près opaque; quelques échantillons montrent une certaine translucidité.

gard to this last rare mineral substance, to which Fergusson never alludes beyond mentioning its existence, I pointed out some time since that seventy-five per cent. of the celts found in the sepulchral dolmen-mounds of Brittany were composed of this material.* Can Mr. Fergusson inform us how he accounts for the presence of this substance, as well as the significance of its predominance in association with sepulture? It may be noted that all the fibrolite celts are small and nearly perfect, with sharp edges, and show no signs of use; whilst the diorite and other celts of a larger type show evident signs of use and are all *purposely* broken before deposition in the dolmen.

VI. P. 356. More strictly the jade and turquoise should be termed *jadéite* and *callaïs*, respectively. Mr. Fergusson is right in quoting "jade" and "turquoise" if he goes by M. René Galles' account, and I quoted the same materials myself in an article on Dolmen Mounds in the *Quarterly Journal of Science* last January; but these

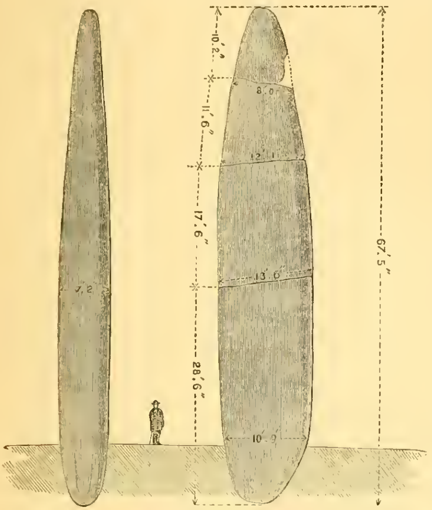

FIG. 3.—LE GRAND MENHIR, Restored by Sir Henry Dryden, Bart., showing its similarity to a Stone Celt.

same articles now in the museum of Vannes are described by the curators Messrs. de Cussé, L. Galles, and D'Ault-dumesnil as *jadéite*† and *callaïs*.‡

VII. How the barrow north of Kerlescant lines can be said to be related in any way (p. 356) to Mont S. Michel (which is situate south-east of the Menec lines, and at least a mile distant), either in position, size, or structure, I cannot imagine. The former is, or rather was, a long but small structure with fashioned entrances, covered over with a mound which is only visible a few yards off, whilst the latter is an immense tumulus, visible from afar, covering one if not more kists of insignificant structure.

VIII. Mr. Borlase's late discoveries in the dolmen-mounds of Trevelgie Head, Cornwall, give additional reasons for supporting Mr. Lukis' theory that both dolmens and cromlechs are merely the skeletons of original chambered tumuli.

IX. P. 389. "Only one drawing of a dolmen in Portugal has as yet, so far as I know, been published."

In 1868 M. Da Costa figured twenty Portuguese dolmens, and eight stone implements found in connection with them.*

"In the Peninsula the cromlechs, when denuded, are known under the name of *Antas* (a term about which there has been much disputing, but which, after all, seems to signify ancient altars used as landmarks); those partially enveloped in the tumulus, or on the summit of a mound, are termed *Mamunhas* (corruption of Mamua or Mamôa—tumulus); and when covered in, as the *allées* and *grottes* of Brittany, they are termed *Furnas*.

"In the year 1734 over three hundred of these remains are mentioned as existing in Portugal, but in 1868 M. da Costa could only enumerate forty-two, of which twenty-eight are in the province of Aleutejo, twelve in Beira, two in Traz-os-Montes, two in Minho, whilst none remain either in Estramadura or D'Algarve.

"The largest aggregation of these antas appears to be at Contado d'Alcogulo, the property of M. Le Cocq, where there are five remaining together. The only stone implements described by M. da Costa were found here, and consist of half a dozen rude greenstone celts and a quartzite muller. With the exception of four, all the above are denuded and ruined antas; the exceptions are two furnas near Vizella in Minho, the Mamunha de Mamaltar in Beira, and the Mamunha de Carrazedo in Traz-os-Montes. This last is chiefly remarkable from the curious hollow circular mark, presumedly artificial, on one of its supports.

"There is also one curious monument mentioned, as composed of two rows of stones, near a menhir between Cepaes and Fafe, in Minho. As this is the sole description of the monument, and no dimensions are mentioned, it is difficult to judge of its composition. It may be analogous to two rows of small vertical stones in the long barrow at Kerlescant, already mentioned, or there may formerly have existed an avenue of stones. Unfortunately it appears that the monument has been destroyed, and the stones made use of in the construction of the neighbouring convent of Pombeiro."†

The above remarks are not written in a carping spirit, but offered merely as additional information to what Sir John Lubbock aptly terms "a rich and trustworthy storehouse of facts," collected with such labour and care by Mr. Fergusson during the last eighteen years.

I will refrain from analysing Mr. Fergusson's theory that the dolmens date from a post-Roman period in the present paper.

Structure à fibres fines, soyeuses, très seerées, contournées, et comme entreacées en divers sens; c'est de là que lui vient son excessive tenacité. Raie e verre et le feldspath, rayée par le quartz. Infusible au chalumeau. Les haches en fibrolite affectent plus ou moins la forme d'un parallélogramme allongé, souvent celle d'un trapèze dont la plus grande base offre un tranchant. La fibrolite étant une substance lamelleuse, toutes les haches faites de cette matière n'ont qu'une épaisseur faible et irrégulière.

* See table.

† La jadéite doit être rattachée à la famille des wernérites (silicates anhydres). Couleur de diverses nuances de vert, de gris verdâtre, de gris jaunâtre, structure cristalline, fibro-lamellaire, quelquefois un peu schistoïde, rayant le feldspath et le jade oriental; rayée par le quartz. Très tenace. Facilement fusible. Une mince écaille, exposée à l'extrémité de la flame d'une lampe á alcool, se fond aisément en un verre jaunâtre ou grisâtre, demi-transparent.

‡ La couleur de cette matière est le vert-pomme, se rapprochant du vert de l'émeraude. Quelques échantillons sont comme marbrés de parties blanches et de parties bleuâtres; d'autres sont maculés de veines et de tâches brunes ou noires, par suite d'un mélange accidentel de matières argileuses. Le minéral est translucide, à peu près autant que la chrysoprase. Sa cassure est compacte comme celle de la cire. Il raie le calcaire, mais il est facilement rayé par une pointe d'acier. Sa poussière est blanche, infusible au chalumeau. Cette substance est un phosphate d'alumine hydraté comme la turquoise orientale, mais elle en diffère sensiblement, aussi bien par les proportions de ses principes constituents que par ses caractères. M. Damour, d'après les différences appréciables qui existent entre ces deux matières, les sépare dans la classification des espèces. Il emprunte à pline le nom de *callais*, qu'il applique à notre minéral, et réserve celui de turquoise à la pierre précieuse de couleur bleu de ciel si connue en joaillerie.

* "Descripçao de Alguns Dolmins ou Antas de Portugal," par F. A. Pereira Da Costa. Lisbon, 1868.

* Types of celts adopted by the *Société Polymathique du Morbihan*, and alluded to in the above table.

DOLMEN-MOUNDS OF BRITTANY AND THEIR INTERIOR STRUCTURES

		No.	Description of Tumulus.	Interior Structure.	Examples.	Remarks.
UNCHAMBERED.		1	Long barrow.	Nil.	Kerlescant (?).	Comparatively rare; there is an erect menhir at west extremity of the examples at Kerlescant, and also a few traces of a revetment.
CHAMBERED.	UNSCULPTURED.	2	Round ditto.	Simple kist. C.*	Carnoet Finistere. Kerlevit, near Douarnenez.	Frequent. In the two examples given, bronze implements were found.
		3	Ditto ditto.	Ordinary megalithic dolmen, consisting of single chamber, with narrow entrance covered way at passage. C.	*Passim.*	This is the commonest type of tumulus, and forms the basis of which the following are variations.
		4	Ditto ditto.	Many-chambered megalithic dolmen, consisting of several chambers with a single narrow entrance. C.	Keriaval. Klud-er-yer.	Most frequent variation of above.
		5	Ditto ditto.	Many-chambered dolmen. Chambers of dry walling, and vaulted narrow entrance, megalithic and ceiled.	Rosmeur.	Not frequent.
		6	Long ditto.	Long, narrow, megalithic chamber, sometimes divided, sometimes with dolmen entrance. C.	Garren-dol. Parc ar Dolmen. Kerlescant. Kerlêarec.	There is a peristalith at Kerlescant. The two latter examples have tolmen entrances.
		7	Round ditto.	Megalithic dolmen, with passage at a sharp angle with chamber. C.	Kergonfals.	A rare example; the entrance passage descends into the chamber, and was found divided by walls of loose masonry.
	SCULPTURED.	8	Ditto ditto.	Megalithic dolmen, with curved gallery or passage. C.	Le Rocher. Pierres Plates.	Le Rocher is yet covered with its tumulus, and is a most unique and perfect specimen. The type of ornamentation (Pierres Plates is denuded) in both is similar.
		9	Ditto ditto.	Two or more megalithic dolmens, either parallel, or at right angles to one another. C.	Grottes de Kerozille. Do. Plouharnel. Kerlan.	At Kerozille, the centre dolmens at right angles to the others; in the other instances the dolmens are parallel to each other.
		10	Ditto ditto.	Square megalithic chamber, and long straight avenue, with elaborate ornamentation. C.	Gavr' Inis.	The most elaborately decorated dolmen known.
		11	Long ditto.	Megalithic dolmen at one extremity, and also other smaller kists, ceiled and vaulted.	Manné Lud. Le Moustoir.	In the first, besides the large dolmen, is a vaulted kist and curious arrangement of stones. In the latter is one dolmen and three other structures, partially megalithic and partially vaulted.
		12	Immense tumuli, more or less elliptical.	Comparatively insignificant. Kists partly megalithic, partly ceiled, and partly vaulted.	Tumiac. Manné-ér-H'roëk. Mont S. Michel.	Tumiac is conical. Inhumation relics. Manné-ér-H'Roëk longer and more truncated, contained no human relics. M. S. Michel long and narrow mound, showed signs of incineration of human remains.

* C = Ceiled.

The Citadel, Plymouth

S. P. OLIVER

NOTES

THE following lectures in pure Science are being delivered this term in Oxford. Prof. Phillips on the Heat of the Interior of the Earth, Ancient Climate, Earthquakes and Volcanos. Prof. Story Maskelyne two courses of lectures;—the first course of four lectures "On the projection of crystals, and on the relations of morphological symmetry to the distribution of physical and especially of optical characters;" second course "On lithology mineralogically considered." Prof. Lawson on Structural and Physiological Botany. He also proposes to make arrangements with his classes for botanical walks. The Professor of Astronomy will give practical instruction in the use of Astronomical Instruments at the Observatory at the Museum. The Chemical and Physical Laboratories are each open as usual, special courses of instruction being given in each. The Professor of Anatomy and Physiology proposes to form classes for practical instruction in Physiology and Anatomy. The Hope Professor of Zoology is engaged in the classification of the Hope, Burchell, and other collections. Dr. Lee's Reader in Chemistry is lecturing on the Non-metallic Elements, the Lee's Reader in Anatomy is lecturing on Comparative Anatomy, and the Lee's Reader in Physics on the Mechanical Theory of Heat, and on Hydro mechanics.

AT the last meeting of the Royal Geographical Society, the President announced the Royal and other awards for the year 1872, made by the Council, as follows:—*Founder's Gold Medal*—Colonel H. Yule, C.B., for his important geographical works "Cathay and the Way Thither," and "Marco Polo." *Patron's Gold Medal.*—Mr. R. B. Shaw, for his adventurous journey to Yarkand and Kashgar, and his observations for fixing the longitude of the former place. *A Gold Watch.*—Lieut. G. C. Musters, R.N., for his journey in Patagonia. 25*l.*—Karl Mauch, for his discoveries in South-East Africa. *Schools Prizes.*—PHYSICAL GEOGRAPHY.—*Gold Medal*—S. E. Spring Rice (Eton College). *Bronze Medal*—A. S. Butler (Liverpool College). *Honourably Mentioned*—C. Penrose (Haileybury); E. Dickson (Cheltenham); J. R. White (Liverpool Institute); H. De Vere Vane (Eton). POLITICAL GEOGRAPHY.—*Gold Medal*—W. G. Collingwood (Liverpool College). *Bronze Medal*—W. C. Graham (Eton). *Honourably Mentioned*—R. H. Sayle (Uppingham); W. L. Kingsford (Rossall); H. E. Dickson (Rossall).

THE *conversazione* of the Royal Society on Saturday evening last was a highly successful one. The company, notwithstanding the counter attraction of the Duke of Edinburgh's reception at the Royal Albert Hall, was a brilliant one, and many of the objects and apparatus exhibited were of great interest. There was a beautiful series of photographs of landscape scenery, the geysers, and mud-springs in the regions of the Yellowstone River explored by Prof. Hayden, exhibited by Mr. A. Tylor; and some of the early photographs of M. Niepce de St. Victor, showing effects of colour; and a collection of Madreporaria dredged up by Count Pourtales from the sea-floor in the course of the Gulf Stream, exhibited by Prof. Duncan. Mr. Browning and Messrs. Elliott Bros. had, as usual, a number of telescopic and spectroscopic instruments.

THE Senate of the University of London has this year re-elected all the old examiners in the Faculties of Science and Medicine, with the exception of the two in Forensic Medicine, the new examiners being Dr. Arthur Gamgee and Prof. Henry Maudsley.

AN Inaugural Meeting of the French Association for the Advancement of Science was held last week at Paris under the presidency of M. Claude Bernard; when the committee of management was elected as follows: MM. Claude Bernard, president; Broca, Delaunay, d'Eichthal, de Quatrefages, Wurtz, Cornu, secretary, and G. Masson, treasurer. It is still undecided whether to hold the first meeting, in August next, at Lyons, Bordeaux, or Lille. M. Wurtz delivered an address on the character and objects of the Association, in which he announced that the requisite guarantee fund of 100,000 fr. is already subscribed, and will probably be considerably exceeded. The movement appears to be meeting with a hearty response from all the leading men of science in France; it is welcomed as an aid in the regeneration of their country, by promoting a spread of scientific knowledge and a love of science throughout the provinces; and we trust it will also have the effect of cementing a closer alliance between French science and that of the other countries of Europe.

THE *Engineer* announces the death, at his residence near London, on April 15, at the age of 84, of Mr. Augustus Siebe. Born in Saxony, he served early in life against the French in the Prussian army; and after the return of peace employed himself first in watch-making, and afterwards in engineering. The perfection of the diving apparatus in particular engaged his attention, and to him are due many of the improvements now in constant use. In this capacity he was sole maker to the Admiralty, his apparatus having been used with great success in the removal of the wreck of the *Royal George*.

DR. PETTIGREW, F.R.S., will deliver a course of lectures on the Physiology of the Circulation in the Lower Animals and in Plants, at the Royal College of Surgeons, Edinburgh, each Friday afternoon, at 4 o'clock, during May, June, and July.

PROF. MAX MULLER gave a public lecture on April 24, at the Taylor Institution, Oxford, "On Darwin's View of Language." There was a large attendance.

THE old Ashmolean Society at Oxford, which was revived last term after a lengthened period of quietude, met on Monday last in the University Museum, when communications were made to the Society by Rev. R. Main, F.R.S., "On the Breaks of Continuity in the Mean Daily Temperature in the months of April and May," and by Mr. A. G. Vernon Harcourt, F.R.S., "On the Sulphur Compounds in Goal Gas, and the means of removing them."

THE garden of the Acclimatisation Society of Paris, ruined during the siege, is about to be reopened. A great part of the damage has been repaired, the ornamental and horticultural parts have been replaced, and there are already many animals in the park.

AT a recent meeting of the French Acclimatisation Society, M. de Grandmont called attention to the project of the Government to establish a grand piscicultural establishment at Montbéliard, to replace that at Huningue, now passed into the hands of the Germans. Very successful establishments of a similar character are now in operation at La Buisse and at Clermont Ferrand (Puy-de-Dôme); the latter, under the direction of M. Rico, furnishing annually not less than 30,000 ova of trout for replenishing the various streams in the department.

THE following excursions are arranged by the Geologists' Association during the present month:—Saturday, May 4, excursion to Erith and Crayford, under the direction of Mr. J. Logan Lobley. The party will leave Cannon Street Station by the North Kent train at 2·10 P.M. for Erith, and will, upon arriving at Erith, inspect the fine section of the Thanet Sands overlying the chalk, exposed at that place. Subsequently the party will proceed to Crayford, and visit the extensive excavations in the Pleistocene Deposits from which have been derived the large collection of Mammalian Remains in the possession of Dr. Spurrel, and inspected by the Association last session.—Saturday, May 11, visit to the British Museum, guided by Mr. Henry Woodward. Members will meet at the Museum, Great Russell

Street, at 2 P.M., and proceed to the Palæontological Department, where a portion of the collection will be described. —Whit-Monday and Tuesday, May 20 and 21, Excursion to Bath (one or two days); directors, Mr. Charles Moore, and the Rev. H. H. Winwood. Monday: Assemble at the Half Moon Hotel (near the Railway Station) at 1 o'clock; proceed to the Museum, the valuable and exceedingly interesting palæontological contents of which will be described by the founder, Mr. Charles Moore; then visit Weston and Twerton, and inspect, under the guidance of the Rev. Mr. Winwood, sections of Lower Lias (*Ammonites Bucklandi* and *A. angulatus* zones). Proceed to Newbridge Hill, where are sections of White Lias and the Rhætic series.—Tuesday: Hampton Down—fine sections of the Great Oolite, and a probable representative of the Bradford Clay; upper beds very fossiliferous (*Terebratula cardium*, *Terebratella Buckmani*, *Crania Antiquorum*, &c., with Corals and Sponges). Dundas in the Bradford Valley —sections showing Marlstone, Upper Lias, and Inferior Oolite. North Bank of Canal—section of Inferior Oolite (*Rhynchonella spinosa* zone), and Fuller's Earth. Cross the Avon to Freshford —Mammiliferous River deposits, yielding *Ovibos moschatus*.

THE prophetic announcements of Prof. Agassiz in regard to the discoveries he intended to make during his proposed deep-sea dredgings in the southern waters continue, according to *Harper's Weekly*, to be realised, as we learn from a letter to Prof. Peirce, dated at Rio on the 12th of February last. The weather had not been favourable for dredging for some time; but a suitable occasion presenting itself, the work was prosecuted for one day, with very interesting results. The first discovery mentioned by the professor was that of a living *Pecten*, very similar in general appearance to a fossil form known as *P. paradoxus*, found in Germany, and which he had been inclined to consider a distinct genus, on account of certain peculiarities which are not shared by any living shells known up to this discovery. The specimen found is, however, strictly referable to the same genus as the *paradoxus*, especially as it has the same prominent radiating ribs arising on the inner surface of the shell valve, to which the fossil is indebted for its specific name. Although of very small dimensions, being scarcely two-thirds of an inch in diameter, it is yet a specimen of very great significance. The second discovery was that of a very remarkable crustacean, and is, in part, the realisation of the expectation of finding "genera reminding us of some amphipods, and isopods aping still more closely the trilobites than *Serolis*." A specimen answering fully to this statement was taken in forty-five fathoms, and at first sight seemed like an ordinary isopod, with a broad, short, flat body. This, however, is not referable to any of the orders or families of Milne-Edwards or Dana, and, for reasons adduced, it has very striking relations to the trilobites, and is, indeed, like them, one of those types combining the structural features of several independent groups. It resembles the trilobites in the fact that the head is distinct from the thoracic regions; and the large faceted eyes and the facial suture across the cheeks connect it so closely that but for the presence of antennæ, which project from the lower side of the anterior margin of the buckler, the resemblance would amount to an absolute identity in structure with the trilobites. The character of the mouth is also that of the trilobite; while the antennæ cause its reference to the isopods. For this new genus the name of *Tomocaris Peircei* is proposed.

DETAILS have been received of the earthquake which devastated Antioch on April 3, to which we referred last week. The Greek church, a strong stone-arched structure, built only a few years ago, and capable of holding 500 or 600 persons, is utterly ruined —one side and the entire roof are gone. The American Protestant church and premises are also greatly injured, and four persons of their small community were killed, though the Mission families are all safe. The number of killed and injured cannot be ascertained with any approach to accuracy, and, of course, flying rumours are abundant, one man saying that he thought there must be 1,000 killed, while another said 500, and a third 250, which is, perhaps, within the truth. There was time from the beginning of the first shock to its close for many to escape the falling houses or walls. Several smaller and lighter shocks occurred for an hour or two afterwards, but not sufficiently strong to shake down buildings. These shocks continued at intervals through the next night; and another, more distinct and wave-like, was felt to shake the house with a loud, hollow, rumbling noise, about half-past six the next morning. The first shock was immediately preceded by a rumbling and creaking of the joints of the window and door frames, to which a louder noise, like thunder, succeeded, and then walls and buildings fell. The old Roman bridge of four arches is rent in several places until the water can be seen through it from above; a part of the parapet wall has also been shaken off, and the arch above the city door at its east end has been hurled down, and lies almost whole. Much damage has been done to houses in the lower part of the town, and many of the inhabitants are now to be seen encamping around in the fields or plain. The shocks appear to have continued, with less severity, for several days. One man declared he counted forty-four shocks within twenty-four hours after the first one. They were all accompanied by a noise like distant thunder or artillery, and produced a tremor of the ground; but no fresh ruin has been made by any of them, except the first great shock about 8 A.M. of the 3rd ult.

EARTHQUAKES are becoming almost as frequent in the Murrumbidgee district in Australia as in New Zealand. The Wagga *Express* reports that recently (in January last) a smart shock was experienced at Crabtree station and several other places on the Upper River. Since June 8—when the first and, with one exception, the heaviest of the shocks was experienced—at least a dozen distinct ones have been felt in this district.

THE Italian Society of Spectroscopists is already doing work which must command the attention of the scientific world. The special object of the Society is to collate the observations of all Italian astronomers, so as to study daily the number, position, size, and form of the protuberances, spots, and faculæ. Three numbers are already published of their *Memorie*, containing the following papers:—An Introduction by Prof. Tacchini, of the Observatory of Palermo, expounding the object and resources of the Society; a memoir by M. Lorenzoni, of the Observatory of Padua, on the spectral analysis of the protuberances; numerical tables to convert into heliocentric coordinates the apparent position of protuberances or spots; a memoir by P. Secchi on a new micrometer for measuring the height of the protuberances; an article by Prof. Tacchini on the comparison of the observations of protuberances made simultaneously in July 1871, at Palermo by himself, and at Rome by Secchi; observations on the solar protuberances and their distribution, by P. Secchi, spectroscopic images of the solar margin, made at Rome, Palermo, and Padua, by Secchi, Tacchini, and Lorenzoni on December 11 and 12, 1871, with a coloured plate. This youngest outcome of solar physics is deserving of the heartiest support of men of science in this country.

ACCORDING to the Sydney *Herald*, the schooner *Surprise* has lately made a visit to the coast of New Guinea, penetrating fifteen miles up the Manoi River. Contrary to the general impression, the natives, who were hitherto supposed to be ferocious in their character and opposed to the visits of strangers, were found to be mild and gentle in disposition. They were of the Malay stock, and had never seen white people before. On the departure of the schooner, under Captain Paget, they exhibited every demonstration of sorrow, the women weeping and the men accompanying the party to a considerable distance

HISTORY OF THE NAMES CAMBRIAN AND SILURIAN IN GEOLOGY*

IT is proposed in the following pages to give a concise account of the progress of investigation of the lower palæozoic rocks during the last forty years. The subject may naturally be divided into three parts: (1) the history of Silurian and Upper Cambrian in Great Britain from 1831 to 1854; (2) that of the still more ancient palæozoic rocks in Scandinavia, Bohemia, and Great Britain up to the present time, including the recognition by Barrande of the so-called primordial palæozoic fauna; (3) the history of the lower palæozoic rocks of North America.

I.—*Silurian and Upper Cambrian in Great Britain.*

Less than forty years since, the various uncrystalline sedimentary rocks beneath the coal-formation in Great Britain and in continental Europe were classed together under the common name of graywacke or grauwacké, a term adopted by geologists from German miners, and originally applied to sandstones and other coarse sedimentary deposits, but extended so as to include associated argillites and limestones. Some progress had been made in the study of this great Graywacke formation, as it was called, and organic remains had been described from various parts of it; but to two British geologists was reserved the honour of bringing order out of this hitherto confused group of strata, and establishing on stratigraphical and palæontological grounds a succession and a geological nomenclature. The work of these two investigators was begun independently and simultaneously in different parts of Great Britain. In 1831 and 1832, Sedgwick made a careful section of the rocks of North Wales from the Menai Strait across the range of Snowdon to the Berwyn hills, thus traversing in a south-eastern direction Caernarvon, Denbigh, and Merionethshire. Already, he tells us, he had in 1831 made out the relations of the Bangor group (including the Llanberis slates and the overlying Harlech grits), and showed that the fossiliferous strata of Snowdon occupy a synclinal, and are stratigraphically several thousand feet above the horizon of the latter. Following up this investigation in 1832, he established the great Merioneth anticlinal, which brings up the lower rocks on the south-east side of Snowdon, and is the key to the structure of North Wales. From these as a base, he constructed a section along the line already indicated, over Great Arenig to the Bala limestone, the whole forming an ascending series of enormous thickness. This limestone in the Berwyn hills is overlaid by many thousand feet of strata as we proceed eastward along the line of section, until at length the eastern dip of the strata is exchanged for a westward one, thus giving to the Berwyn chain, like that of Snowdon, a synclinal structure. As a consequence of this, the limestone of Bala re-appears on the eastern side of the Berwyns, underlain as before by a descending series of slates and porphyries. These results, with sections, were brought before the British Association for the Advancement of Science at its meeting at Oxford in 1832; but only a brief and imperfect account of the communication of Sedgwick on this occasion appears in the Proceedings of the Association. He did not at this time give any distinctive name to the series of rocks in question (L.E. and D. Philos. Mag. (1854) IV., viii. 495).

Meanwhile in the same year, 1831, Murchison began the examination of the rocks on the river Wye, along the southern border of Radnorshire. In the next four years he extended his researches through this and the adjoining counties of Hereford and Salop, distinguishing in this region four separate geological formations, each characterised by peculiar fossils. These formations were moreover traced by him to the south-westward across the counties of Brecon and Caermarthen; thus forming a belt of fossiliferous rocks stretching from near Shrewsbury to the mouth of the river Towey, a distance of about 100 miles along the north-west border of the great Old Red Sandstone formation, as it was then called, of the West of England.

The results of his labours among the rocks of this region for the first three years were set forth by Murchison in two papers presented by him to the Geological Society of London in January 1834 (Proc. Geol. Soc. ii., 11). The formations were then named as follows in descending order:—(1) Ludlow, (2) Wenlock, constituting together an upper group; (3) Caradoc, (4) Llandeilo (or Builth), forming a lower group. The Llandeilo formation, according to him, was underlain by what he called the Longmynd and Gwastaden rocks. The non-fossiliferous strata of the Longmynd hills in Shropshire were described as rising up to the east from beneath the Llandeilo rocks; and as appearing again in South Wales, at the same geological horizon, at Gwastaden in Breconshire, and to the west of Llandovery in Caermarthenshire; constituting an underlying series of contorted slaty rocks many thousand feet in thickness, and destitute of organic remains. The position of these rocks in South Wales was, however, to the north-west, while the strata of the Longmynd, as we have seen, appear to the east of the fossiliferous formations.

In the "Philosophical Magazine" for July, 1835, Murchison gave to the four formations above named the designation of Silurian, in allusion, as is well known, to the ancient British tribe of the Silures. It now became desirable to find a suitable name for the great inferior series, which, according to Murchison, rose from beneath his lowest Silurian formations to the north-west, and appeared to be widely spread in Wales. Knowing that Sedgwick had long been engaged in the study of these rocks, Murchison, as he tells us, urged him to give them a British geographical name. Sedgwick accordingly proposed for this great series of Welsh rocks, the appropriate designation of Cambrian, which was at once adopted by Murchison for the strata supposed by him to underlie his Silurian system. (Murchison, Anniv. Address, 1842; Proc. Geol. Soc. iii., 641.) This was almost simultaneous with the giving of the name of Silurian; for in August 1835, Sedgwick and Murchison made communications to the British Association at Dublin on Cambrian and Silurian Rocks. These, in the Volume of Proceedings (pp. 59, 60) appear as a joint paper, though from the text they would seem to have been separate. Sedgwick then described the Cambrian rocks of North Wales as including three divisions: 1. The Upper Cambrian, which occupies the greater part of the chain of the Berwyns, where, according to him, it was connected with the Llandeilo formation of the Silurian. To the next lower division, Sedgwick gave the name of Middle Cambrian, making up all the higher mountains of Caernarvon and Merionethshire, and including the roofing-slates and flagstones of this region. This middle group, according to him, afforded a few organic remains, as at the top of Snowdon. The inferior division, designated as Lower Cambrian, included the crystalline rocks of the south-west coast of Caernarvon and a considerable portion of Anglesea, and consisted of chloritic and micaceous schists, with slaty quartzites and subordinate beds of serpentine and granular limestone; the whole without organic remains.

These crystalline rocks were, however, soon afterwards excluded by him from the Cambrian series; for in 1838 (Proc. Geol. Soc. ii., 679) Sedgwick describes further the section from the Menai Strait to the Berwyns, and assigns to the chloritic and micaceous schists of Anglesea and Caernarvon a position inferior to the Cambrian, which he divides into two parts; viz., Lower Cambrian, comprehending the old slate series, up to the Bala limestone beds; and Upper Cambrian, including the Bala beds and the strata above them in the Berwyn chain, to which he gave the name of the Bala group. The dividing line between the two portions was subsequently extended downwards by Sedgwick to the summit of the Arenig slates and porphyries. The lower division was afterwards subdivided by him into the Bangor group (to which the name of Lower Cambrian was henceforth to be restricted), including the Llanberis roofing-slates and the Harlech grits or Barmouth sandstones; and the Festiniog group, which included the Lingula flags and the succeeding Tremadoc slates.

In the communication of Murchison to the same Dublin meeting, in August 1835, he repeated the description of the four formations to which he had just given the name of Silurian; which were, in descending order, Ludlow and Wenlock (Upper Silurian), and Caradoc and Llandeilo (Lower Silurian). The latter formation was then declared by Murchison to constitute the base of the Silurian system, and to offer in many places in South Wales distinct passages to the underlying slaty rocks, which were, according to him, the Upper Cambrian of Sedgwick.

Meanwhile, to go back to 1834, we find that after Murchison had, in his communication to the Geological Society, defined the relation of his Llandeilo formation to the underlying slaty series, but before the names of Silurian and Cambrian had been given to these respectively, Sedgwick and Murchison visited together the principal sections of these rocks from Caermarthenshire to Denbighshire. The greater part of this region was unknown to Sedgwick, but had already been studied by Murchison, who interpreted the sections to his companion in conformity with the scheme already given; according to which the beds of the Llan-

* Reprinted from advance sheets of the *Canadian Naturalist*.

dello were underlain by the slaty rocks which appear along their north-western border. When, however, they entered the region which had already been examined by Sedgwick, and reached the section on the east side of the Berwyns, the fossiliferous beds of Meifod were at once pronounced by Murchison to be typical Caradoc, while others in the vicinity were regarded as Llandeilo. The beds of Meifod had, on palæontological grounds, been by Sedgwick identified with those of Glyn Ceirog, which are seen to be immediately overlain by Wenlock rocks. These determinations of Murchison were, as Sedgwick tells us, accepted by him with great reluctance, inasmuch as they involved the upper part of his Cambrian section in most perplexing difficulties. When, however, they crossed together the Berwyn chain to Bala, the limestones in this locality were found to contain fossils nearly agreeing with those of the so-called Caradoc of Meifod. The examination of the section here presented showed, however, that these limestones are overlain by a series of several thousand feet of strata bearing no resemblance, either in fossils or in physical characters, to the Wenlock formation which overlies the Caradoc beds of Glyn Ceirog. This series was, therefore, by Murchison supposed to be identical with the rocks which, in South Wales, he had placed beneath the Llandeilo, and he expressly declared that the Bala group could not be brought within the limits of his Silurian system. It may here be added that in 1842 Sedgwick re-examined this region, accompanied by that skilled palæontologist, Salter, confirming the accuracy of his former sections, and showing moreover by the evidence of fossils that the beds of Meifod, Glyn Ceirog, and Bala, are very nearly on one parallel. Yet, with the evidence of the fossils before him, Murchison, in 1834, placed the first two in his Silurian system, and the last deep down in the Upper Cambrian; and consequently was aware that on palæontological grounds it was impossible to separate the lower portion of his Silurian system from the Upper Cambrian of Sedgwick. (These names are here used for convenience, although we are speaking of a time when they had not been applied to designate the rocks in question.)

This fact was repeatedly insisted upon by Sedgwick, who, in the Syllabus of his Cambridge lectures, published very early in 1837, enumerated the principal genera and species of Upper Cambrian fossils, many of which were by him declared to be the same with those of the Lower Silurian rocks of Murchison. Again, in enumerating in the same Syllabus the characteristic species of the Bala limestone, it is added by Sedgwick: "all of which are common to the Lower Silurian system." This was again insisted upon by him in 1838 and 1841. (Proc. Geol. Soc. ii. 679; iii. 548.) It was not until 1840 that Bowman announced the same conclusion, which was reiterated by Sharpe in 1842. (Ramsay, Mem. Geol Sur. iii., part 2, p. 6.)

In 1839 Murchison published his "Silurian System," dedicated to Sedgwick, a magnificent work in two volumes quarto, with a separate map, numerous sections, and figures of fossils. The succession of the Silurian rocks, as there given, was precisely that already set forth by the author in 1834, and again in 1835; being, in descending order, Ludlow and Wenlock, constituting the Upper Silurian, and Caradoc and Llandeilo (including the Lower Llandeilo beds or Stiper-stones) the Lower Silurian. These are underlain by the Cambrian rocks, into which the Llandeilo was said to offer a transition marked by beds of passage. Murchison in fact declared that it was impossible to draw any line of separation, either lithological, zoological, or stratigraphical, between the base of the Silurian beds (Llandeilo) and the upper portion of the Cambrian, the whole forming, according to him, in Caermarthenshire, one continuous and conformable series from the Cambrian to the Ludlow. ("Silurian System," pp. 256, 358.) By Cambrian in this connection we are to understand only the Upper Cambrian or Bala group of Sedgwick, as appears from the express statement of Murchison, who alludes to the Cambrian of Sedgwick as including all the older slaty rocks of Wales, and as divided into three groups, but proceeds to say that in his present work (the "Silurian System") he shall notice only the highest of these three.

Since January 1834, when Murchison first announced the stratigraphical relations of the lower division of what he afterwards called the Silurian system, the aspect of the case had materially changed. This division was no longer underlain, both to the east in Shropshire and to the west in Wales, by a great unfossiliferous series. His observations in the vicinity of the Berwyn hills with Sedgwick in 1834, and the subsequently published statements of the latter had shown, that this supposed older series was not without fossils; but on the contrary, in North Wales, at least, held a fauna identical with that characterising the Lower Silurian. Hence the assertion of Murchison in his "Silurian System," in 1839, that it was not possible to draw any line of demarcation between them. The position was very embarrassing to the author of the "Silurian System," and for the moment, not less so to the discoverer of the Upper Cambrian series. Meanwhile, the latter, as we have seen, in 1842 re-examined with Salter his Upper Cambrian sections in North Wales, and satisfied himself of the correctness, both structurally and palæontologically, of his former determinations. Murchison, in his Anniversary Address as President of the Geological Society in 1842, after recounting, as we have already done, the history of the naming by Sedgwick in 1839 of the Cambrian series, which Murchison supposed to underlie his Silurian system, proceeded as follows:—"Nothing precise was then known of the organic contents of this lower or Cambrian system, except that some of the fossils contained in its upper members in certain prominent localities were published Lower Silurian species. Meanwhile, by adopting the word Cambrian, my friend and myself were certain that whatever might prove to be its zoological distinctions, this great system of slaty rocks being evidently inferior to those zones which had been worked out as Silurian types, no ambiguity could hereafter arise. . . . In regard, however, to a descending zoological order, it still remained to be proved whether there was any type of fossils in the mass of the Cambrian rocks different from those of the Lower Silurian series. If the appeal to nature should be answered in the negative, then it was clear that the Lower Silurian type must be considered the true base of what I had named the protozoic rocks; but if characteristic new forms were discovered, then would the Cambrian rocks, whose place was so well established in the descending series, have also their own fauna, and the palæozoic base would necessarily be removed to a lower horizon." If the first of these alternatives should be established, or in other words, if the fauna of the Cambrian rocks was found to be identical with that of the Lower Silurian, then, in the author's language, "the term Cambrian must cease to be used in zoological classification, it being, in that sense, synonymous with Lower Silurian." That such was the result of palæontological inquiry, Murchison proceeded to show, by repeating the announcements already made by Sedgwick in 1837 and 1838, that the collections made by the latter from the great series of fossiliferous strata in the Berwyns, from Bala, from Snowden, and other Cambrian tracts, were identical with the Lower Silurian forms. These strata, it was said, contain throughout "the same forms of *Orthis* which typify the Lower Silurian rocks." It was further declared by Murchison in this address that researches in Germany, Belgium, and Russia led to the conclusion that the "fossiliferous strata characterised by Lower Silurian Orthidæ are the oldest beds in which organic life has been detected." (Proc. Geol. Soc. iii. 641, &c.) The Orthids here referred to are, according to Salter, *Orthis calligramma*, Dalm, and its varieties. (Mem. Geol. Survey iii, part 2, 335-337.)

Meanwhile Sedgwick's views and position began to be misrepresented. In 1842 Mr. Sharpe, after calling attention to the fact that the fossils of the Bala limestone were, as Sedgwick had long before shown, identical with those of Murchison's Lower Silurian, declared that Sedgwick had placed the Upper Cambrian, in which the Bala beds were included, beneath the Silurian, and that this determination had been adopted by Murchison on Sedgwick's authority. (Proc. Geol. Soc. iv. 10.) This statement Murchison suffered to pass uncorrected in a complimentary review of Sharpe's paper in his next annual address (1843.) In his "Siluria," 1st edition, p. 25 (1854), he speaks of the term Cambrian as applied (in 1835) by Sedgwick and himself "to a vast succession of *fossiliferous* strata containing undescribed fossils, the whole of which were supposed to rise up from beneath well-known Silurian rocks. The Government geologists have shown that this *supposed* order of superposition was erroneous," &c. The italics are the author's. Such language, coupled with Mr. Sharpe's assertion noticed above, helped to fix upon Sedgwick the responsibility of Murchison's error. Although the historical sketch which precedes clearly shows the real position of Sedgwick in the matter, we may quote further his own words:—"I have often spoken of the great Upper Cambrian group of North Wales as inferior to the Silurian system, . . on the sole authority of the Lower Silurian sections, and the author's many times repeated explanations of them before they were published. So great was my confidence in his work, that I received it as perfectly established truth that his order of superposition was unassailable. . . . I asserted again and again that the Bala limestone was near the base of the so-called Upper

Cambrian group. Murchison asserted and illustrated by sections the unvarying fact that his Llandeilo flag was superior to the Upper Cambrian group. There was no difference between us until his Llandeilo sections were proved to be wrong." (Philos. Mag. IV. viii. 506.) That there must be a great mistake in Sedgwick's or in Murchison's sections was evident, and the Government surveyors, while sustaining the correctness of those of Sedgwick, have shown the sections of Murchison to have been completely erroneous.

The first step towards an exposure of the errors of the Silurian sections is, however, due to Sedgwick and McCoy. In order better to understand the present aspect of the question, it will be necessary to state in a few words some of the results which have been arrived at by the Government surveyors in their studies of the rocks in question, as set forth by Ramsay in the Memoirs of the Geological Survey. In the section of the Berwyns, the thin bed of about twenty feet of Bala limestone, which (as originally described by Sedgwick) they have found outcropping on both sides of the synclinal chain, is shown to be intercalated in a vast thickness of Caradoc rocks; being overlain by about 3,300 and underlain by 4,500 feet of strata belonging to this formation. Beneath these are 4,500 feet additional of beds described as Llandeilo, which rest unconformably upon the Lingula-flags just to the west of Bala; thus making a thickness of over 12,000 feet of strata belonging to the Bala group of Sedgwick. A small portion of rocks referred to the Wenlock formation occupies the synclinal above mentioned. (Memoirs, III. part 2, 214,222.) The second member, in ascending order, of the Silurian system, to which the name of Caradoc was given by him in 1839, was originally described by Murchison under the names of the Horderly and May Hill sandstone. The higher portions of the Caradoc were subsequently distinguished by the Government surveyors as the Lower and Upper Llandovery rocks; the latter (constituting the May Hill sandstone, and known also as the Pentamerus beds) being by them regarded as the summit of the Caradoc formation. In 1852, however, Sedgwick and McCoy showed from its fauna that the May Hill sandstone belongs rather to the overlying Wenlock than to the Caradoc formation, and marks a distinct palæontological horizon.

This discovery led the geological surveyors to re-examine the Silurian sections, when it was found by Aveline that there exists in Shropshire a complete and visible want of conformity between the underlying formations and the May Hill sandstone; the latter in some places resting upon the nearly vertical Longmynd rocks, and in others upon the Llandeilo flags, the Caradoc proper or Bala group, and the Lower Llandovery beds. Again, in South Wales, near Builth, the May Hill sandstone or Upper Llandovery rests upon Lower Llandeilo beds; while at Noeth Grug the overlying formation is traced transgressively from the Lower Llandovery across the Caradoc to the Llandeilo. These important results were soon confirmed by Ramsay and by Sedgwick. (Ibid, 4, 236). The May Hill sandstone often includes, near its base, conglomerate beds made up of the ruins of the older formation. To the north-east, in the typical Silurian country, it is of great thickness and continuity, but gradually thins out to the south-west. There exists, moreover, another region where not less curious discoveries were made. About forty miles to the eastward of the typical region in South Wales appear some important areas of Silurian rocks. These are the Woolhope beds, appearing through the Old Red Sandstone, and the deposits of Abberley, the Malverns and May Hill rising along its eastern border, and covered along their eastern base by the newer Mesozoic sandstone. The rocks of these localities were by Murchison in his "Silurian System" described as offering the complete sequence. When however it was found that his Caradoc included two unconformable series, examination showed that there was no representative of the older Caradoc or Bala group in these eastern regions, but that the so-called Caradoc was nothing but the Upper Llandovery or May Hill sandstone. The immediately underlying strata, which Murchison had regarded as Llandeilo, or rather as the beds of passage from Llandeilo to Cambrian, and had compared with the north-west passage of the Caermarthenshire sections (Syl. Sys. 416), have since been found to be much more ancient deposits, of Middle Cambrian age, which rests upon the crystalline hypozoic rocks of the Malverns, and are uncomformably overlain by the May Hill sandstone. We shall again revert to this region, which has been carefully studied and described by Prof. John Phillips. (Mem. Geol. Sur. II., part 1.) T. STERRY HUNT

(*To be continued*)

SCIENTIFIC SERIALS

THE *Révue Scientifique*, Nos. 33—42. The first article in these numbers is by Prof. Huxley, on Yeast.—The conclusion is arrived at of M. de Quatrefages' course of lectures on Anthropology, at the Museum of Natural History at Paris.—M. de Fonvielle contributes an article on Balloon Observations. In No. 34. M. Léon Le Fort, Professor to the Faculty of Medicine at Paris, furnishes an account of military surgery in the Austrian army.—Among the contributions from foreign sources is a report of M. Vogel's spectroscopic observations of the planets made in 1871 at the observatory of Bothkamp.—No. 35 contains an interesting lecture, delivered at the University of Friberg-in-Brisgau, by M. Ecker, on the struggle for existence in the character and in the life of nations.—In No. 36 is commenced a report, continued in subsequent numbers, of M. Claude Bernard's course of lectures at the College of France on Animal Heat. A translation is given of a paper by Prof. Harting, of Utrecht, on the artificial production of organic calcareous formations. There are also reports of the proceedings of English and other foreign scientific societies.—In No. 37 the most interesting paper is one by Dr. Onimus, on the consecutive phenomena attendant on the removal of the brain, and on the movements of rotation, illustrated with drawings of frogs and birds, on which the operation had been performed, to show the action.—No. 38 contains a report of Prof. Virchow's address to the Congress of German Naturalists and Physicians at Rostock, on Science in the national life of Germany. Sir William Thomson's paper on the Size of Atoms is translated from an early number of this journal. M. Papillon has an article in support of M. Wurtz's aphorism, "Chemistry is a French science, constituted by Lavoisier," in reply to English and German attacks.—No. 39 commences with an important article by M. P. Lorain, on Reform in the Higher Instruction. A translation is given of M. R. Wolf's lecture at the University of Zurich on Solar Spots, and of Neumayer's paper contributed to the Vienna *k. k. Geologische Reichsanstalt* on the Jurassic Basins.—In No. 40 M. Le Fort supplements his previous paper by an additional one on Military Surgery in the Prussian army. This and the following number are partially filled with further reports of the Rostock meeting of German naturalists and physicians.—In No. 41 we find also a lecture by M. Lereboullet at the School of Military Health at Montpellier on the Spinal Column.—No. 42 contains a report of M. Blanchard's address to the Annual Congress of the Learned Societies of the Departments at the Sorbonne. M. Paul de Saint Robert contributes a paper with the suggestive title, "Qu'est ce que la force?" There are also a number of reports of the proceedings of foreign societies.

THE *Journal of Botany* for April commences with an interesting article by Prof. Babington on the *Anacharis alsinastrum* or Canadian water-weed. He shows clearly that there are two series of plants closely resembling each other in appearance, of which one series has perfect triandrous flowers, and the other has incomplete diœcious flowers, of which the males are nearly or quite sessile, and have the curious habit of becoming detached when the pollen is ripe, and floating freely about on the surface of the water, and shedding their pollen there. To the first series belongs the *Elodea* of South America; to the second, *Anacharis* and *Hydrilla*. *Anacharis* would therefore appear to be the true genus to which the English (introduced) plant belongs, as given by Hooker, but not by Bentham and Syme.—Mr. Baker gives one of his useful synoptical revisions of the Cape species of *Anthericum*; and Prof. Thiselton Dyer a history of the substance known as "Australian Caoutchouc," and a valuable account of the mode of germination of *Tropæolum*, which is characteristic rather of endogens than of exogens.

Annalen der Chemie und Pharmacie, January 1872. This number commences with a paper by Max Ascher on the trisubstitution derivation of benzine; this is an attempt to establish the constitution of some of these bodies, but at present, however, it has not been entirely successful.—The next paper is by Linnemann and Zotta "On the reduction of formic acid to formaldehyde and methyl alcohol;" the authors followed exactly the same process as was described by Lieben and Rossi some time since, and which has already been noticed in these pages. The next three communications are by Linnemann "On normal propyl alcohol, its compounds and its conversion into isopropyl alcohol." The author prepared the normal alcohol in two ways—by the action of nascent hydrogen on propionic anhydride, and by obtaining the aldehyde by distillation of calcic

propionate and formiate, and subsequent treatment with sodium amalgam. The normal alcohol was converted into isopropyl alcohol by preparing from it the iodide, and from this the cyanide, which by treatment with potash yields propylamine. Propylamine hydrochloride on heating with argentic nitrate and water yields isopropyl alcohol, having the characteristic properties and reactions of this body.—Hugo Schiff follows "On the constitution of æsculin;" this is an important theoretical paper.—Quinke contributes the second part of his memoir, "On a new class of aromatic hydrocarbons." By the action of benzyl chloride on toluol, benzyl toluol $C_{14}H_{14}$ is formed with elimination of hydrochloric acid. By oxidation, this hydrocarbon yields benzylbenzoic acid $C_{14}H_{10}O_2$; this by the action of nascent hydrogen yields benzhydrylbenzoic acid $C_{14}H_{12}O_2$; and by the treatment with hydriodic acid the latter yields benzylbenzoic acid $C_{14}H_{12}O_2$.—Translations of two papers, which have already appeared in the French journals, and also a paper by Maly, complete this number.

THE *Journal of the Franklin Institute* for February, after the usual editorial paragraphs descriptive of novelties, has an article by Prof. H. B. Thurston, on Experimental Steam Boiler Explosions, containing a report of a series of experiments undertaken by a committee of the Institute, in conjunction with several railway engineers, for the purpose of testing the conditions under which steam boilers explode—Mr. F. A. Genth continues his paper on the Mineral Resources of North Carolina; and Mr. J. P. Cooke his Chemical Theory of the Voltaic Battery, the portion in the present number being devoted to Electricity.—Prof. P. E. Chase gives a Table of Cyclical Rainfalls at Lisbon, in support of the theory already advanced by him of the lunar influence on the weather. The other papers in this number are mostly of a purely mathematical character.

The first original article in the number for March is chiefly of local interest—"The Locomotive Engine, and Philadelphia's share in its Early Improvements," by J. Harrison, jun., the last recipient of the Rumford Gold Medal.—Mr. James Emerson gives a Report of Water-wheel Tests at Lowell and other places, illustrated with plates.—In another paper on Experimental Steam Boiler Explosions, Prof. Thurston discusses the third experiment at Sandy Hook, New York.—Mr. Joseph S. Smith describes the construction of the Keokak and Hamilton Bridge across the Mississippi, connecting the States of Iowa and Illinois.—Dr. Richard Owen, of the Indiana State University, details a series of experiments on Terrestrial Magnetism.—Prof. R. E. Chase gives tables of the Monthly Rainfall at San Francisco.

THE first article in the *American Journal of Science and Arts* for March is a most interesting account, by Prof. Hayden, of the Hot Springs and Geysers of the Yellowstone and Firehole rivers, accompanied by illustrations and maps. The description of these geysers, which throw those of Iceland completely into the shade, will not bear epitomising, but is well worth reading as a whole.—Two other geological articles are by Prof. Dana, on the Quartzite of the Green Mountains, and by Prof. Silliman, Geological and Mineralogical Notes on some of the mining districts of Utah territory.—Prof. A. E. Verril contributes two instalments of his contributions to zoology, from the Museum of Yale College, on the affinities of Palæozoic Tabulate Corals with existing species, and recent additions to the molluscan fauna of New England.—The other article of greatest interest is by Prof. H. A. Nicholson of Toronto, on the genera *Cornulites* and *Tentaculites*, and on a new genus *Conchicolites*.

THE *Quarterly Journal of Science* for April commences with an article by Mr. R. A. Proctor on Meteoric Astronomy. In reference to the researches of Signor Schiaparelli, he gives an account of the meteoric systems through which the earth passes in August and November, and seeks in meteoric pheuomena and the associated phenomena of comets the explanation of some of the features presented by the solar corona. The zodiacal light he explains also on the theory of its being the outer portion of the sun-surrounding meteor families.—Mr. James Douglas, of Quebec, gives a description of the copper mines of Chili, and of the geological and mineralogical features of the country where they occur.—An article on Natural and Artificial Flight describes the results arrived at by Dr. Pettigrew in the case of the flight of birds and insects, and consists to a large extent of extracts from that gentleman's memoirs contributed to the Transactions of the Linnean Society and of the Royal Society of Edinburgh.—Mr. William Topley, in an article on the Geology of the Straits of Dover, illustrated by sections, advocates the project proposed by Hawkshaw and Low of a submarine tunnel, to run from near the South Foreland to a point between Sangatte and Calais, which he believes will pass entirely through the chalk, and will not be likely to be attended by any insuperable engineering difficulties.—An article on the Gold Coinage, and a short one by Captain Oliver on Recent Changes in British Artillery Material, complete the original portion of the number.—Only four books are reviewed this quarter, and more than half the space allotted to reviews is occupied by a notice, by Mr. A. R. Wallace, of Mr. Dale Owen's "The Debatable Land between this World and the Next," in which the reasonableness of the alleged phenomena of modern Spiritualism is advocated.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, April 25.—"On a supposed Periodicity in the Elements of Terrestrial Magnetism, with a period of $26\frac{1}{3}$ days." By George Biddell Airy, Astronomer Royal, P.R.S.

In a paper published in the "Proceedings of the Imperial Academy of Sciences of Vienna," vol. lxiv., Dr. Karl Hernstein has exhibited the results of a series of observations which appeared to show that the earth's magnetism undergoes a periodical change in successive periods of $26\frac{1}{3}$ days, which might with great plausibility be referred to the rotation of the sun.

It appeared to the author that the deductions from the magnetic oqservations made at the Royal Observatory of Greenwich, and which are printed annually in the "Greenwich Observations," or in the detached copies of "Results of Magnetical and Meteorological Observations made at the Royal Observatory of Greenwich," would afford good materials for testing the accuracy of this law, as applicable to a series of years.

The mean for declination in 1870, and, still more remarkably, the mean for horizontal force in 1870, appear to exhibit an increase about the fourteenth day. But the author does not remark in the other means, either as given in numerals or as projected as curves, anything to support the idea of an inequality periodical in the $26\frac{1}{3}$ days. It might almost be suspected that the secular changes used in the period 1850-1852 are too large; but no alteration of these renders the inequality of $26\frac{1}{3}$ days more probable. Dr. Hornstein's investigation was limited to observations made in 1870.

Royal Geographical Society, April 22.—General Sir Henry C. Rawlinson, K.C.B., president, in the chair. "On Recent Explorations of the North Polar Region, by Captain Sherard Osborn, R.N. Captain Osborn commenced by alluding to his advocacy of a Polar Expedition *via* Smith Sound, in 1865, and stated that the Duke of Somerset, then First Lord of the Admiralty, though apparently sufficiently favourable to the general proposal of a Government Expedition, urged upon him by a deputation from the Society who waited on him in that year, declined to assume the responsibility of recommending an expedition, owing to the difference of opinion which then reigned with regard to the best route to be followed. The alternate route to Smith Sound was that by the seas of Spitzbergen, advocated by Dr. Petermann and others, on the ground that the Gulf Stream, flowing in that direction, maintained an open sea to the Pole. He (Captain Osborn) and the promoters of the Expedition were content to wait the result of efforts made soon after by the Swedes and Germans to carry out the views of the German geographer. Seven years had elapsed, and we were now in a position to say that the advocates of the Spitzbergen route had been proved entirely wrong, whilst those who believed Smith Sound to be the best route were right. Captain Koldeway, who commanded both the German Expeditions, states, as the result of all his efforts, that "one can hardly resist the conviction that the hope of attaining the North Pole by ship, or of finding an open sea around the Pole, are alike among the most improbable of things. I confess that I myself was misled by representations in Dr. Petermann's 'Geographische Mittheilungen,' and held it to be at least possible by following a line of coast to penetrate by ship far into the central Arctic region, and then certainly to make one's way to the Pole. A winter in East Greenland, the most careful observation of these mighty masses of ice, their movements and formation, and of the whole condition of temperature, have radically cured me and all my companions of this idea. . . . If the principal object be the nearest possible approach to the Pole, I am quite of Osborn's opinion that the best way appears to be through Smith Sound. Here one can penetrate by ship every year to the 78th parallel, and then one has a

continuous line of coast running north, which has been sighted as far as the 82nd parallel. Along this coast one would have to work one's way in spring with dog-sledges. I consider it a wild undertaking to penetrate towards the Pole by ship between Spitzbergen and Nova Zembla." No one could undo the effect of evidence so honest and conclusive as this. The Duke of Somerset rested his decision to delay action on the importance of first being furnished with the results of the Swedish Expedition, then on its way to Spitzbergen. The Swedes during the last seven or eight years had sent no less than four expeditions to the verge of the Polar region; and the conclusion of their scientific leader, Von Nordenskiöld, is that in summer it is not possible to penetrate by ship through the pack, and that an open Polar Sea is a mere hypothesis destitute of foundation. The Swedish authorities further state that the only way to approach the Pole is that proposed by the English Arctic officers, of exploring on sledges in the spring. Here, then, are the results for which the First Lord of the Admiralty in 1865 desired to wait. After a review of the voyage of the Austrian Lieutenants Payer and Weyprecht last summer, in which they found open sea a little to the north and west of Nova Zembla, and which discovery is to be followed up by a second expedition in the present summer, Capt. Osborn concluded by an eloquent appeal to the English people not to allow the final laurels of Polar discovery to be wrung from them by the sailors or explorers of any other nation. In the discussion which followed, Dr. J. D. Hooker spoke of the important questions in the science of botany which a North Polar Expedition alone could elucidate; such as the extension nearer the Pole of fossil plants like those of Disco in Greenland, which indicate a former temperate climate in 70° north. Dr. Carpenter advocated a Polar Expedition as a necessary complement to the one the Government were about to despatch to the Pacific to investigate the deep-sea ocean currents, and so forth. Accurate investigations of current-temperature, &c., of the Polar Ocean were of the highest importance to the right comprehension of the true theory of oceanic movements. Admiral Sir George Back stated that he entirely approved of the Smith Sound route as the one best to be adopted for a North Polar Expedition. Sir Leopold M'Clintock also spoke to similar effect. Admiral Richards explained the interest attaching to the completion of the geography of Greenland, which ought to be achieved by the English. He was strongly of opinion that a Government expedition, and by the English, was alone competent to finish the work of Arctic discovery. Mr. R. H. Scott read a letter from Von Nordenskiöld, in which he stated that a Swedish expedition would start for Spitzbergen this summer, winter in the islands to the north, and attempt a journey towards the Pole in May, 1873, with reindeer-sledges.

Anthropological Institute, April 8.—Sir John Lubbock, Bart., president, in the chair. Mr. Hyde Clarke read a note on the Hamath Inscriptions. The remainder of the evening was occupied by an exhibition and description, by Mr. Edward Charlesworth, of certain objects from the Crag of Suffolk simulating human workmanship. A long and animated discussion ensued, and the question was postponed until such time as Mr. Charlesworth could lay before the Institute, in the form of a paper, his matured opinion based upon reliable evidence.

April 22.—Dr. Charnock, vice-president, in the chair. Mr. Hyde Clarke contributed a further note on the Hamath Inscriptions and their comparison with Himyarite and Lybian.—A paper by Dr. Barnard Davis, F.R.S., was read "On the Hair and some other peculiarities of Oceanic Races." The paper was illustrated by a large and beautiful series of specimens of hair showing all the varieties of dressing, ornamentation, preparation, bleaching, &c., employed by a great number of races and tribes.—Dr. Henry Blanc also exhibited a specimen of long hair from the head of a Hindustanee.—A paper by Dr. Rink "On the Descent of the Esquimaux" was read, in which the author showed from traditionary and historical evidence that that race was truly American, and not Asiatic in its origin, as some ethnologists had maintained.—Dr. Charnock read a paper "On Le Sette Communi." The district lay nearly north of Vicenza. The people were the remnants of those Germans who obtained an asylum in that country after having been vanquished by Theodoric, King of the Ostrogoths, who died A.D. 526. There had been many marriages with the Italians, and the people more resembled the latter than the Germans There were, however, many with fair hair and German features. The people were simple in their manners, honest, poor, dirty, and superstitious. The author noticed no cases of goître or cretinism. The paper concluded with a vocabulary and ample remarks on the grammar of the dialect, which resembled the Hochdeutsch of the 13th century, still spoken in Southern Bavaria. It had some words from the Italian.

Meteorological Society, April 17.—Dr. Tripe, president, in the chair. A paper was read "On the Temperature of Hill and Valley," by Mr. G. Dines. The observations in the valley were made at Cobham, and those on the hill at Denbies, the difference in height being about 600 feet; both the thermometer stands are those known as "Glaisher's," and the instruments are by Casella. The observations extend over eighteen months. The air on the hill is colder in the day and warmer at night than in the valley; and the daily range of temperature at the higher station is not so great as at the lower, the average being only about $4\frac{1}{2}°$. In cold weather it is found that the air on top of the hill is never so cold as that in the valley. The rainfall also on the hill is 40 per cent. greater than in the valley. It has been said that "the air on top of a hill is drier and colder than in the valley," but the results arrived at in this paper show that the contrary is the case. In the discussion which followed, Mr. Glaisher said that he had always found in his balloon ascents that the temperature decreased as he ascended, and was colder and more uniform the higher he went, but at night he found that the temperature was warmer than on the ground, and it was this that led him to place thermometers at the height of 4 ft., 22 ft., and 50 ft. above the ground, and the results obtained show that the air is sometimes 5° or 6° colder at 50 ft. than at 4 ft. in the day time, and 3° or 4° warmer at night time. Colonel Strange said that the temperature was colder on mountain tops both in day and night than in the valley. Dr. Mann thought that the temperature of the air directly above the earth in a balloon, and the temperature on top of a hill at the same height, would be quite different. The Rev. F. W. Stow had made several observations which showed that the air was warmer at the upper station and colder at the lower. Mr. Strachan remarked that unless the thermometers were protected from radiation the readings would be too high. Mr. Gaster said that solar radiation was out of the question, because the air is colder on top of the hill than in the valley when the sun is shining, and warmer at night when it is not shining, and he thought the more abrupt the hill the more would the observations coincide with those taken in a balloon at the same height.—The next paper was by Mr. C. O. F. Cator "On Certain Defects in Anemometric Registration." The author said that correct records cannot be obtained by the present method, that the sheets should be much longer, and made to move more quickly. A correct register of the velocity of the wind is not obtained because the cups cannot take up the motion directly at each gust, and in a lull the cups revolve too quickly on account of the momentum received from the previous gust. In registering the pressure of the wind, the sheets and the scale should be longer, because at present the very small amounts are scarcely shown, and in gales the paper is completely black from the constant movements of the pencil, but if the sheet were moved more quickly each separate pressure might be recorded.

PARIS

Academy of Sciences, April 22.—M. Camille Jordan read a note on the forms reduced from congruences of the second degree.—M. de Saint-Venant presented a paper on a complement to be given to one of the equations presented by M. Levy for plastic movements which are symmetrical around an axis.—A note was read by M. J. Montier on the internal work which accompanies the escape of a gas without variation of heat; and one by M. P. Desains on the reflection of heat at the surface of polished bodies.—Several notices more or less closely relating to auroras were read, namely, a note by M. Fron, presented by M. Delaunay, on the auroral period from the 10th to the 16th April, 1872, and its relations to the movements of the atmosphere; a portion of a letter from M. Donati to M. Delaunay, relating chiefly to phenomena of terrestrial magnetism observed during the time of manifestation of auroras; a claim of priority in proposing the theory of the solar origin of magnetic auroras, by M. H. Tarry; a continuation of M. J. Silbermann's paper on the relations existing between terrestrial meteorology and the movements of celestial bodies; and a note by M. Duponchel, in which that gentleman ascribes the origin of auroras to the modification of the calorific waves after sunset; as these then cease to traverse the atmosphere and become tangential with it, especially in the neighbourhood of the poles, he supposes them to produce there

effects of light and perhaps of electricity.—M. Bellanger forwarded a note on the change which takes place in the boiling point of water when mixed with more volatile fluids.—M. Faye presented a note on the photographic studies of the sun which have recently been undertaken at the observatory of the Infante Don Luiz, at Lisbon.—A letter from Father Secchi on some peculiarities of the constitution of the sun was read; as also a note by M. W. de Fonvielle on the hypothesis of the magnetisation of the sun.—M. V. Raulin presented a note on the pluviometric observations made at Athens from 1859 to 1871, including tables of monthly mean rainfalls and other data.—A note by M. de Lafollye, on a mode of determining copper by means of cyanide of potassium, was read. This is a volumetric process performed by adding a standard solution of cyanide of potassium to a solution of a salt of copper coloured blue by ammonia, until the complete decolorisation of the latter.—M. E. Ferrière presented a note on the action of sulphuric ether upon iodides, in which he states that, by the addition of sulphuric ether to the solution of an iodide, the iodine is gradually entirely set free. He ascribes this action to the slow but continuous formation of an unstable hydriodic ether.—M. Wurtz communicated a note on the synthesis of orcine, by MM. G. Vogt and A. Henninger. This body was obtained by the authors by the action of potash in fusion upon the sulpho-conjugate acid of chlorinated toluene.—M. C. Robin presented a note by M. Rabauteau, on the physiological properties possessed by the various proximate principles of opium.—A note by M. Sanson, on the hybrids produced between the hare and the rabbit, was communicated by M. Milne-Edwards. The author stated that the production of fertile hybrids between these two species had certainly been effected in 1868 by M. E. Gayot, who had furnished him with individuals of the sixth generation, representing two varieties which have been established and called by the breeder the *Léporide ordinaire* and the *Léporide longue-soie*. The former is identical with the rabbit in its specific characters; the latter closely approaches the hare.—M. Milne-Edwards also presented a note by M. A. F. Marion on Rotatoria parasitic upon *Nebaliæ*. The author noticed the occurrence upon *Nebalia straussii* of a *Saccobdella* distinct from that observed by Van Beneden and Hesse on *N. geoffroyi*.—A note by M. H. Sicard on the respiratory apparatus of *Zonites algirus* was also presented by M. Milne-Edwards; as also a note on the termination of the vertebral column in the Pleuronectidæ by M. H. E. Sauvage.—M. de Quatrefages communicated a note by M. E. T. Hamy on the proportional development of the humerus and radius in man, in which the author noticed the relative lengths of these bones at various ages, and gave a table showing the gradual and very considerable diminution in the proportional length of the radius to the humerus on reaching the adult condition.—M. F. Garrigou presented a note on the unity of composition of the Pyrenees proper, and the chain commonly called the *Petites Pyrénées*. He maintained that no distinction can be drawn between them.—M. de Quatrefages communicated an extract from a letter by M. E. B. des Essards on sea shocks.

VIENNA

Imperial Academy of Sciences, March 7.—Prof. E. Hering, of Prague, transmitted a memoir by M. F. Hofmeister, containing investigations upon the connective tissue in the testes of the Mammalia.—Prof. V. Graber, of Graz, transmitted a preliminary report on the propulsory blood apparatus of insects, and on the occurrence of a true elastic fibrous net in the Hymenoptera.—Prof. L. Gegenbauer, of Krems, forwarded a memoir entitled "The Universalised Dirchlet's Integral;" and Dr. A. Boué delivered a discourse upon geological chronology.

March 14.—Prof. L. Gegenbauer transmitted a memoir on Definite Integrals.—Dr. F. Wallentin communicated a memoir on the Serial Development of Functions, and its employment in Algebraic Analysis, as well as in the Integration of Differential Equations.—A paper on the Destruction of the *nervus facialis* and its consequences, by M. Schauta, was presented by Prof. Brücke. The experiments were made on two young rabbits.—Prof. von Lang communicated a note by Prof. Handl, on the absolute intensity and absorption of light.—M. E. Priwoznik presented two communications, of which the first contained a chemical investigation of the coating formed upon an antique bronze implement found in an old Celtic grave, near Hallstatt; and the second the results of a series of experiments made upon the formation of the sulphides of copper, silver, tin, nickel, and iron, to which the former investigation gave rise. The crust which covered the bronze consisted of three layers, of which the outermost and thickest was formed of blue sulphide of copper; the second was blackish-gray, and composed of disulphide of copper with 15 per cent. of tin; and the third, or innermost, was formed of a black powder containing 23·2 per cent. of tin, together with the accidental constituents of the bronze, arsenic, antimony, and nickel.

BOOKS RECEIVED

ENGLISH.—Corals and Coral Islands: J. D. Dana (S. Low, Son, and Co.).—Introduction to Biology: H. Alleyne Nicholson (Blackwoods).—Natural Philosophy: E. Atkinson (Longmans).—Mountaineering in the Sierra Nevada: C. King (S. Low, Son, and Co.).—Lecture Notes to Chemical Students, Vol. ii., Organic Chemistry: E. Frankland. 2nd edition (Van Voorst).—The Principle and Practice of Canal and River Engineering: D. Stevenson. 2nd edition (A. and C. Black).

AMERICAN.—Gateways to the Pole: S. Bent (Studley, S. Louis).

DIARY

THURSDAY, MAY 2.

ROYAL SOCIETY, at 8.30.—On a new Great Theodolite (illustrated by the instrument) to be used on the Great Trigonometrical Survey of India, with a short Note on the Performance of a Zenith Sector employed on the same work: Col. Strange, F.R.S.—On some Elementary Principles in Animal Mechanics—V. and VI.: Rev. Prof. Haughton, F.R.S.

SOCIETY OF ANTIQUARIES, at 8.30.—Exhibition of Early Christian Rings: C. D. E. Fortnum, F.S.A.—Vortigern, not Hengest, the Invader of Kent: H. C. Coote, F.S.A.—Excavations of Tumuli at Trevalga: W. C. Borlase, F.S.A.

LINNEAN SOCIETY, at 8.—On *Alibertia edulis*: Señor Correa de Mello.

CHEMICAL SOCIETY, at 8.—On the Manufacture of Iron and Steel: E. Riley.

ROYAL INSTITUTION, at 3.—On Heat and Light: Prof. Tyndall, F.R.S.

FRIDAY, MAY 3.

ROYAL INSTITUTION, at 9.—On Optical Phenomena produced by Crystals when submitted to Circularly Polarised Light: W. Spottiswoode.

GEOLOGISTS' ASSOCIATION, at 8.—On Columnar Basalts: J. Curry.—On a Visit to the Diamond Fields of South Africa, with Notices of Geological Phenomena by the wayside: J. Paterson.

SATURDAY, MAY 4.

ROYAL INSTITUTION, at 3.—The Star-Depths: R. A. Proctor.

GOVERNMENT SCHOOL OF MINES, at 8.—On Geology: Dr. Cobbold, F.R.S.

MONDAY, MAY 6.

ENTOMOLOGICAL SOCIETY, at 8.—On the Longicorn Fauna of Nicaragua: H. W. Bates.

ANTHROPOLOGICAL INSTITUTE, at 8.—Peculiarities of the Australian Cranium: Mr. Bradley.—A Scaphoid Skull: Dr. Barnard Davis, F.R.S.—The Basque Race: Rev. W. Webster and Mr. Menteath.—Marm, its Names and their Origin: Mr. Jeffcott.—Queensland Dialects: Mrs. Barlow.—Preservation of Australian Dead: Mr. M'Donald.

ROYAL INSTITUTION, at 2.—General Monthly Meeting.

TUESDAY, MAY 7.

ZOOLOGICAL SOCIETY, at 9.—On Dinornis (Part XVIII.) containing a description of the pelvis and bones of the leg of *Dinornis gravis*: Prof. Owen, F.R.S.—Appendix to a List of Birds known to inhabit the Island of Celebes: Viscount Walden.—On the habits of the Swallows of the genus *Progne*, met with in the Argentine Republic, with notes by P. L. Sclater: W. H. Hudson.

SOCIETY OF BIBLICAL ARCHÆOLOGY, at 8.30.

ROYAL INSTITUTION, at 3.—On the Development of Belief and Custom amongst the Lower Races of Mankind: E. B. Tylor, F.R.S.

WEDNESDAY, MAY 8.

GEOLOGICAL SOCIETY, at 8.—Notes on Atolls or Lagoon Islands: S. J. Whitnell.—On the Glacial Phenomena of the Yorkshire Uplands: J. R. Dakyns.—On Modern Glacial Action in Canada: Rev. W. Bleasdell, M.A.—On a Sea-coast Section of Boulder Clay in Cheshire: D. Mackintosh.

SOCIETY OF ARTS, at 8.—On the Use of a Revolving Rabble in the common Puddling Furnace: F. A. Paget.

THURSDAY, MAY 9.

ROYAL INSTITUTION, at 3.—On Heat and Light: Prof. Tyndall, F.R.S.

SOCIETY OF ANTIQUARIES, at 8.30.

MATHEMATICAL SOCIETY, at 8.

MENTAL DARKNESS IN HIGH PLACES

WE have long ago been told in the most forcible language and by the highest authority what will be the fate of a people whose leaders are blind; and the same authority has likewise informed us that the worst possible form of darkness is that in which we think we see. To have a one-sided, a short-sighted, or a distorted view of any principle or policy is frequently worse than not to see it at all, more especially in those who claim to wield the national power or to direct the national will. To have a short-sighted steersman is very bad, especially if the navigation be dangerous; but what must be the fate of the vessel if her steersman and look-out are both equally short-sighted?

It is at the present moment a point of vital importance that our leaders should be well informed as to the true nature of the claims advanced by Science for a better recognition by the Government of this country. Yet we question very much whether the leaders of Government have a just conception as to what is demanded by men of science, and why it is demanded, nor do we think that some of our leading journals are much better informed.

We quote the following extract from the *Times* of April 26, referring to a speech made by Mr. Gladstone at the annual banquet of the Civil Engineers:—

"'A fair field and no favour' is the maxim of English administration. A field so fair, so extensive, and so promising, that all industry may find its place, and such an absence of favour that one as well as another may hope for success. If under such conditions of Government the State 'does nothing for Science,' it cannot be helped, nor need it be much lamented, considering how very little Science stands in need of the aid."

We will do Mr. Gladstone and the *Times* the justice to own that these sentiments embody much that is true. To be meddling and muddling in private concerns is certainly not the province of any Government; and some think that the present Government were wrong when they undertook the management of the telegraphs.

The State should neither on the one hand attempt too much, nor on the other hand should it neglect to perform its obvious duties. What, then, are the principles which should guide a conscientious and intelligent Government as to its action in such matters? There can, we think, be no doubt as to these principles. If a certain course of procedure be for the obvious benefit of the whole people, and if its accomplishment be beyond the power of private associations, but not beyond that of Government, then surely it ought to be undertaken.

Let us test the truth of this maxim by one or two illustrations. It is for the obvious benefit of this country that it should have good steam communication with the continent of Europe and with America. Nevertheless our steam packets ought certainly to remain as they are, in the hands of private companies. Natural laws may here be left to themselves, and they will doubtless work in such a manner that the companies will on the one hand receive a handsome profit, while the public will on the other hand be supplied with efficient steam communication.

Again, it is of great importance that the country should be well furnished with animal food, and here, as before the task of supplying it may with advantage be left to private enterprise.

But in connection with this supply, we come to a case in which Government have very properly interfered. It is very important that the meat should be good and wholesome, and that diseased cattle should not be imported. On the other hand the people themselves, apart from Government, have no power of stopping the importation of such cattle, and therefore Government have very properly come forward and lent their aid in securing to the people a thoroughly wholesome supply of animal food.

It will at once be seen from these and similar instances, that legislative interference is uncalled for wherever natural laws are at work to perform the required objects.

Such natural laws are in operation in all, or nearly all, of the arts and industries of life. To meddle with carpenters, or bricklayers, or shoemakers, is entirely beyond the province of Government. If a man has a genius for improving shoes, he must not expect Government to start him in business; but he must look around for the cooperation of a capitalist; in fact, he must carry his genius to market and dispose of it to the highest bidder.

But what if the man have a genius for discovering natural laws? Will Mr. Gladstone or the *Times* be good enough to indicate the whereabouts of the market in which his genius will be rewarded? We have just been told that it is not at the Treasury; well, but where is it? Or will they tell us that such a discovery will never be of any practical advantage? Hardly so; the time for saying such things is past. It will in all probability be of immense importance to all industries, and they will all derive much profit in consequence of this man's discovery; yet he himself will derive none.

But we need not here attempt to prove that the advancement of Science is a question of national importance. This has been already demonstrated very conclusively by Col. Strange and others who have recently devoted much attention to the subject. We pass on to consider whether its advancement can be undertaken by private bodies, such as the Royal Society or the British Association.

The recent actions of these bodies speak for themselves. The former has just discontinued a series of sun observations taken under its superintendence; while the latter has given up the maintenance of the Kew Observatory—both on the plea of want of funds. Again, the maintenance of meteorological observatories has already been undertaken by Government as a thing beyond the means of private individuals.

In all directions the spread of Science is cramped by this want of money; to illustrate which we shall conclude by giving a short account of the recent attempt made by the British Association to establish a series of electrical standards on a scientific basis. One of the most important, and at the same time most difficult, determinations was that of the unit of resistance. In order to establish this unit upon the principles proposed by Weber and Thomson, it was necessary to associate together in an experimental investigation a scientific electrician, a mathematician, a metallurgist, and the director of a magnetic observatory. It was necessary first of all to determine the best kind of wire in which to embody the

standard, and this required numerous experiments by a metallurgist; it was necessary to know what changes took place in the magnetism of the earth during the experiments, and this required the attendance of the director of a magnetical observatory; a scientific electrician presided over the experiments, and associated himself with a mathematician who was well versed in the theory of electricity. The unit of resistance thus determined by the British Association has now been universally adopted by practical engineers; men of science have laboured, and the Postmaster-General has quietly entered into the fruits of their labour; but the experiments in connection with other units are not yet finished; in fact such researches, requiring as they do great skill and time for their accomplishment, must necessarily hang fire if the men who can perform them do not receive some support which will enable them to devote their best energies to the conduct of these and similar experiments.

We have now said enough to establish our point that the extension of Science is of national importance, and that in its present state this extension is beyond the means of private individuals, but not beyond the means of the State. Before concluding, we ought to mention (more especially since it cannot be gathered from the *Times* report) that one of our most distinguished men of science, Dr. Joule, was present at the banquet to which we have alluded, and in returning thanks for Science took the opportunity of stating that he trusted Science would soon obtain that recognition which it imperatively required. If men of science will be true to themselves and to their noble cause, we feel confident that sooner or later they will prevail.

HOOD ON BONE-SETTING

On Bone-Setting. By Wharton P. Hood, M.D., M.R.C.S. (Macmillan and Co., 1871.)

TO any but the professional reader this title is not attractive; and yet we are greatly mistaken if the book itself does not prove to the full as attractive and as lastingly interesting to the intelligent non-professional as to the professional reader; and this, not because the subject is lowered to the level of general comprehension, or written in what is called a "popular" style, but simply because the subject itself is of such wide and varied interest, and its whole treatment in the present little volume is so frank, so clear, and so convincing.

It will be asked, What is bone-setting, who are the bone-setters, and who are their patients? And it will be readily answered, Why, of course, bone-setting is the art of setting bones that have been broken, or joints that have been dislocated, and this is done, doubtless, by surgeons; and equally doubtless and of course, their patients are persons whose bones are fractured, or whose joints are dislocated—

There needs no ghost come from the grave to tell us that.

Perhaps not, but the answer is quite wrong for all that; quite the reverse indeed of what is actually the case, for bone-setting is *not* the art of re-setting broken bones or dislocated joints; bone-setters are *not* surgeons, or regular practitioners in any sense of the title; and their patients, even when they have suffered injury to joint or bone, have been pronounced by the regular practitioner *cured* before seeking the help of the bone-setter.

Having stated this triple paradox, let us hear what Dr. Hood has to say in explanation.

"A healthy man sustains a fracture of one or both bones of the fore-arm, and applies at a hospital, where splints are adapted in the usual way. He is made an out-patient, and the splints are occasionally taken off and replaced. After the lapse of a certain number of weeks the fracture becomes firmly united, the splints are laid aside, and the man is discharged as cured. He is still unable to use either his hand or his fore-arm, but is assured that his difficulty arises only from the stiffness incidental to long rest of them, and that it will soon disappear. Instead of disappearing, however, it rather increases, and in due time he seeks the aid of a bone-setter. . . . The bone-setter would then by a rapid manipulation, hereafter to be described, at once overcome the stiffness of the fingers, and enable the patient to move them to and fro. The instant benefit received would dispel all scruples about submitting the wrist and the elbow to manipulation, and these would be set free in their turn. The man would go away easily flexing and extending his lately rigid joints, &c."

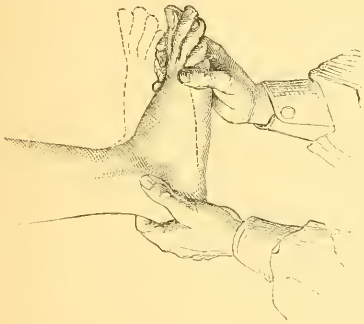
Now what was the cause of stiffness in the foregoing typical case? What was the nature of the impediment to normal movement, ignored by the surgeon and overcome by the bone-setter? The impediment above indicated, it is argued, might arise from articular inflammation, producing adhesions between surfaces "resting in apposition," and that such adhesions, if so placed as to restrain movement, will cause pain and irritation whenever they are rendered tense; and, moreover, that inflammation sufficient to produce these adhesions may be insidiously set up in a joint by extension from neighbouring structures—as in the above-recited case. Again, it is argued, "possibly in some cases, the proper ligaments may become contracted or rigid, or adherent to neighbouring parts; in others, internal or external adventitious fibrous bands may be formed; in others, muscles may have undergone shortening. Again, effusion may have become solidified, and thus movement be impaired, as if by a state of things analogous to a rusty hinge." And further on: "If we consider the amount and character of the effusion which takes place after some sprains and injuries, in some gouty and rheumatic affections, and in some cases of suppuration occurring in bursa, or beneath deep fascia, we cannot doubt that such effusion may easily assume forms in which it will tie down muscles, tendons, or even articular nerves themselves."

The art of bone-setting, then, is the art of overcoming these impediments in joints, these conditions of arrested or impaired freedom which not unfrequently supervene on the curative processes of treatment in use by surgeons in cases of fracture or dislocation; or which may arise from, and be observed only after the subsidence of, active rheumatism, gout, ganglionic swellings, or other local affections; and this brings us to the question, How is it done? how are these stiffened joints set free? how are these impediments to healthy action overcome? The answer of the regular practitioner is that which has been already quoted, namely, to rest it—advice which usually entails a distressing failure; the answer of the irregular practitioner, *i.e.*, the bone-setter, is precisely the opposite, namely, that freedom can only be restored to the stiffened joint by movement, by manipulation, and manipulation too of the most formidable kind, nothing less than suddenly and forcibly rupturing, tearing asunder, the adhesions formed

between the articulating surfaces of the affected joint, an operation which is so frequently successful that it forms the very basis of the bone-setting craft.

It is here that the bone-setter steps in front of the scientific surgeon, and we must confess to a feeling of disappointment that their relative positions are not reversed, that the surgeon is not called in to rectify the malpractices of the quack, instead of the latter being sought out to complete the shortcomings of the former. Let us see how this manipulation is performed. The bone-setter has a clearly defined system of treatment for each separate joint, if not for each specific affection to which each joint is subject. Next to the list of authenticated cases of successful treatment, this is, perhaps, the most valuable part of the treatise; for in addition to the ample and detailed modes of procedure with each joint, diagrams showing the act of manipulation are given, taking in succession those of the upper and lower limbs, and also of the several regions of the spinal column. One example may here be given:—

"The proximal side of the affected joint being firmly held, and the thumb-pressure made in the ordinary way, the tarsus is so grasped as to give the greatest attainable leverage, the foot twisted a little inwards or outwards,



then sharply bent up upon the leg and again straightened. As a rule it is desirable to execute this manœuvre twice over with an inward and once with an outward twist, and also to take care that the movements of the joint are free in all directions."

Bone-setters, we are told, are for the most part uneducated men, wholly ignorant of anatomy and pathology; but we are not told what we greatly wish to know, and that is, the manner and method in which the secrets, the mysteries, and the traditions of their craft, are communicated to each other. No doubt there exists a freemasonry in the craft, so that when individual members meet revelations are made and notes compared, but we are not informed of any regular or organised system of instruction, either for the maintenance and extension of the craft, as a craft, or for the enlightenment of the separate and detached members of the fraternity. The most celebrated, we may even say distinguished, bone-setter of our day was the late Mr. Hutton, whose successful treatment of cases that had baffled the skill of the foremost surgeons now living, cases related in detail by Dr. Hood, and about the accuracy of which there can be no question or doubt, is little short of marvellous; and the question is ever recurrent while we read, "How and where was this skill acquired?" for a bone-setter of Mr. Hutton's calibre could put his finger on the spot where lurked the seat of an affection that had crippled a patient for half-a-dozen years, and had defied the scientific treatment of the ablest surgeons of our time; nay, he could point to this spot without ever seeing the limb affected, guided merely by observing the attitude, gait, or action of the patient. Now, whence comes this undoubted skill of these illiterate men? It appears to be obtained solely by observation of symptoms and results of treatment, the accumulated knowledge of from day to day experience; and as we often see that one sense is quickened and functional power increased by the loss or impairment of some other sense, so perhaps the narrowing of the field of instruction, the limiting of the sources of information, may have intensified the powers of observation of the bone-setters, atoning in a measure for the absence of the revelations of science.

It was from Mr. Hutton himself that Dr. Hood received the secrets of the craft. The motive for, and the manner of, making this revelation are so interesting, that we must give them in Dr. Hood's own words:—

"About six years ago my father, Dr. Peter Hood, in conjunction with Dr. Iles, of Watford, attended the late Mr. Hutton, the famous bone-setter, through a long and severe illness. On his recovery my father refused to take any fees from Mr. Hutton, out of consideration for the benefit which he had rendered to many poor people. Mr. Hutton expressed himself as being thereby placed under great obligation, and as being very desirous of doing something to show his gratitude. He offered as an acknowledgment of the kindness he had received to explain and show all the details of his practice as a bone-setter. Pressure of work prevented my father from availing himself of this offer, and Mr. Hutton then extended it to me. After some consideration I determined to accept it, and accordingly I went, when I could spare the time, to Mr. Hutton's London house, on the days of his attendance there. My decision was prompted, not only by the curiosity I felt to see how he treated the cases that came under his care, but also by the desire to make known to the profession, at some future time, any insight that I could gain into the apparent mystery of his frequent success."

By this means Dr. Hood in time found himself, as he tells us further on, able to take charge of all Mr. Hutton's poorer class of patients, "whom he was accustomed to attend gratuitously," and found that he could accomplish all that he had seen done. "And this practice," he elsewhere emphatically says, "gave me knowledge of a kind that is not conveyed in ordinary surgical teaching—that when guided by anatomy is of the highest practical value, as well in preventive as in curative treatment."

With this knowledge, thus acquired, the author's course was clear. In a series of letters in the *Lancet* he communicated to his professional brethren some of its most important facts, and now to the general reading public he submits the whole in the shape of a well-arranged and clearly-written volume.

ARCHIBALD MACLAREN

OUR BOOK SHELF

Worms; a Series of Lectures on Practical Helminthology, delivered at the Middlesex Hospital, by T. Spencer Cobbold, M.D., F.R.S. (London: Churchill, 1872.)

These lectures do not pretend to give any very minute anatomical details, or any full account of the life history of the remarkable group of animals of which they treat, and which Dr. Cobbold has so long and so carefully investigated. They were originally delivered to medical students, but are so simply and clearly written that they might advantageously be read by the public. They show the frequency with which parasites occur in man, and the necessity of careful supervision of the animal food exposed in our markets for sale, especially at night and to the poor. Dr. Cobbold remarks that the terms "measly mutton" and "measly beef" are terms which will sound strange to those who know of no other "measled meat" than pork; but he points out that his investigations have incontestably proved and verified the existence of larval tapeworms in the most esteemed kinds of animal food. The tapeworms derived from these three kinds of meat, beef, mutton, and pork, though agreeing in their general characteristics, yet differ in minor points, and especially in the shape of their heads. The head of the beef tapeworm is destitute of hooks, and has four large suckers, besides a supplementary fifth (so called); whilst the head of the pork tapeworm is a trifle smaller, and furnished with a slightly prominent proboscis, armed with a double row of hooks. The mutton tapeworm is also armed, at least the "measle" is provided with hooks. A fully-developed beef tapeworm numbers about eleven hundred joints, and attains its full development in about thirteen weeks or rather less. Dr. Cobbold appears to regard the well-made ethereal extract of the root of male fern as by far the best remedy for tapeworm, though kousso, kamala, turpentine, panna, pumpkin seeds, betel nuts, and the bark of the pomegranate, are occasionally successful in effecting their expulsion, and will sometimes accomplish this when the oil of male fern has failed. In regard to thread worms (*Oxyuris vermicularis*) Dr. Cobbold states that it is quite a mistake to suppose the lower bowel or rectum forms their special habitat. He recommends santorine, with active saline purgatives, and copious enemata, for their removal. The large, round worm, *Ascaris lumbricoides*, and the *Ascaris mystax*, are in his experience rare, the latter, indeed, very rare in England, but they are endemic in some regions, as in the Mauritius. The Trichina appears to have been only once recognised and treated in the human subject, namely, by Dr. Dickenson, of Worthington. In this instance Dr. Cobbold calculated that the patient played the host to forty million of the parasites. He observes that when once the Trichina has gained admission to our muscles, all hopes of dislodging it are at an end; but if a person suspects that he has eaten diseased or trichinised meat, he should lose no time in seeking assistance. Immediate advice, followed by a suitable antitrichinalic, might be the means of saving his life, whereas a few days' delay would perhaps prove fatal. Whilst the worms are in the intestinal canal we can get rid of them, but when once the trichinal brood migrates into the flesh no means are known by which their expulsion can be effected. The work terminates with some amusing cases of spurious worms.

H. P.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Recent Climatic Changes

In two previous letters I have tried to show that the land is gaining on the sea at both poles; in other words that the periphery of the earth is being thrust out in the direction of its shorter axis. If this change has been so great as to make it probable that the Classical and Arabic accounts were correct when they made Scandinavia an archipelago in the earlier centuries of our era, we may be sure that it has not been without material influence upon other physical phenomena, and notably upon climate.

One obvious result of the conversion of a great space of water into an area of dry land in the high latitudes confined by the Arctic and Antarctic circles, would be to alter very materially the mean climate of both hemispheres. This has been noted by many inquirers into the subject, and not least by Mr. Hopkins in his very ingenious criticism of the different potential climatic revolutions which are consistent with the presence or absence of certain elements like the one we are dealing with. Ingenious and most interesting as Mr. Hopkins's well-known paper in the *Geological Transactions* is, it does not, I think, quite explain facts as observed. I am not writing in emulation of one who has every claim to be considered an authority, but in the humbler guise of a student whom you are always willing to assist, who desires some of your correspondents to throw light on a difficult and neglected question.

The increase of land at the poles at the expense of the water will tend to intensify the extremes of temperature in winter and summer, and in consequence, to make the climate much less constant and uniform and much more severe; and we ought to find evidence of this somewhere, if the premisses of my two previous letters are tenable. I wish to adduce a few facts in the way of such evidence, and to ask your correspondents for more either pro or con. Many such must exist.

Greenland is a name which seems ironical under present conditions of climate. It has always seemed to me that the land there has changed its appearance very considerably since that name was applied to it. The Esquimaux were apparently not known as inhabitants of Greenland to the Saga writers. The skzellings they met with were on the coasts of Labrador and farther South. They first appeared after the black plague had nearly destroyed the Norse settlements, and they completed the work the pestilence had commenced. They came from the north, probably from the area now occupied by the so-called Arctic Highlanders. The Indians who now live along the march, or frontier, bounding them and the Esquimaux in North America, have an apparently uniform tradition, that the Esquimaux were formerly not neighbours of theirs, and that they came south across the sea from the islands beyond. I believe that I have sufficient facts by me to justify the opinion that the Esquimaux of both shores of Behrings Straits have been constantly drifting westwards and southwards, and that they are but recent occupants of their present area there. This will appear in a future communication to the Anthropological Institute. These facts are quoted to show that the Esquimaux race has been uniformly leaving its more northern habitat and seeking a more southern one. It is remarkable that the recent Swedish Expeditions to the Eastern Coasts of Greenland found abundance of reindeer and musk-oxen there in areas formerly uninhabited by both animals. This emigration must have come from the north. I can see no adequate cause for a revolution affecting men as well as other animals in such a uniform manner, except the continuously increased severity of local climates which has driven the inhabitants farther south.

Iceland has notoriously become more harsh and untenable in its climate since the days of the Norsemen. I will quote from a capital authority, Henderson's Journal in Iceland, pages 6 and 7:—"It is evident from ancient Icelandic documents that on the arrival of the Norwegians, and for centuries afterwards, pretty extensive forests grew in different parts of the island, and furnished the inhabitants with wood both for domestic and nautical purposes. Owing, however, to the improvident treatment of them, *and the increased severity of the climate*, they have almost entirely disappeared, and what remains scarcely deserves any other name than that of underwood, consisting for the most part of birch, willow, and mountain ash. That grain was produced in former times in Iceland appears from the names of many places, such as akkrar, akkrances, akkraheron, &c., the word *akr* signifying a cornfield, and from certain laws in the ancient code, in which express mention is made of such fields, and a number of regulations are prescribed relative to their division and cultivation." Grain is no longer raised there. The Black Death, and other reasons, have been adduced for this cessation; but these are clearly inadequate causes, the real reason being no doubt the same which has caused grain culture to be discontinued elsewhere, namely, the increased severity of the climate.

What is true of Iceland is also true of Norway, in the most northern parts of which we find many names compounded with the Norse word for barley, proving, as the best authorities agree, that barley then grew where it grows no longer. In Scotland many places show signs of the plough, and of having been sown with cereals where arable farming is now unpractised. It is notorious that not only in Scotland, but even in England as far south as Lancashire, large districts that were once covered with forests are now entirely bare of trees, and not only so, but trees cannot be made to grow there. "The Romans planted vineyards and made wine in parts of England where the hop will now hardly grow."

In Northern Russia beyond the Dwina there is a vast area, formerly known as Biarmia, studded with the graves and other remains of a very prosperous people, whose wealth and civilisation are much descanted about by the Saga writers. Othere, the navigator, whose story was translated by Alfred, tells us that it was on arriving in their country after the dreary voyage round the North Cape, that he first again met with tilled fields and an agricultural race. This area is now deserted except by a few hunters and fishermen; the ancient inhabitants have moved westward and southward into Finland, &c. I have described the migration in a paper to be printed by the Anthropological Institute. The best authenticated case of this desolation is the increased severity of the climate, which makes agriculture almost unendurable there. The Norse traders used to frequent Cholmogorod, the port of Biarmia, in great numbers, both for traffic and for fishing. This navigation continued until the early part of the thirteenth century, when we are told it was gradually put an end to by the increased difficulties with the ice in the White Sea, which becomes practically choked with ice; and when the English found their way to Archangel in the sixteenth century, so forgotten was this old trade, that the journey was treated as one of discovery.

Farther east facts are less accessible. The following quotations from von Wrangel's voyage illustrates my position:—

"In 1810 Hedenstrom went across the tundra direct to Utsjansk. He says, 'On the tundra *equally remote from the present line of trees* among the steep sandy banks of the lakes and rivers, are found large birch trees complete with bark, branches, and roots. At first sight they appear well preserved, but on digging them up they are found to be in a thorough state of decay. On being lighted they glow, but never burst into flame. The inhabitants use them for fuel. They call them Adamonshtshina (*i.e.* of Adam's time). *The first living birch trees are not now found nearer than 3° to the south, and then only as shrubs.*' . . . . . 'Another cliff, 30 or 35 feet high, beyond the Malaya Kurspataschnaja river, consists of ice, clay, and black earth. On drawing out some interspersed roots we found them to be birch, and as fresh as if only just severed from the trees. *The nearest woods are 100 versts off.*'" These facts show how far to the south the limit of trees has been pushed quite in recent times in Siberia, that is, how much more severe the Siberian climate has become—a fact, perhaps, connected with the persistent south-westerly drifting of Ugrian tribes from this area which has taken place during the historic period. The flora of our own bogs must disclose evidences of some kind on this subject. I should be thankful to any of your correspondents for facts which illustrate the question drawn from this or any other source.

Will you allow me to correct two printer's errors in my last letter. Africa has been inserted instead of Arica, and Mine Journal instead of Same Journal, *i.e.*, Journal of the Geological Society. Both errors due to my execrable writing.

HENRY H. HOWORTH

A New Mode of taking Casts

IT has been suggested to me that an account of "A New Mode of taking Casts," reported in NATURE, May 2, 1872, might convey the impression that I claimed any share in the invention. Modelling wax has been employed for this purpose in France by the late M. Edouard Lartet, and I have to thank Prof. Busk, F.R.S., for having first brought the use of the material before my notice. My sole object was to formulate the process according to my own experience of its utility, that it might be employed by others for the multiplication of type specimens, without any idea of claiming its invention.

W. BOYD DAWKINS

Norman Road, Rusholme, Manchester, May 3

The Denudation of the Mendips

IN the address of the President of the Geological Society of London reported in NATURE No. 129, page 490, it is stated that "Denudation has removed from the crest of the Mendips a mass of strata possibly equal to two miles or more in height, and from that of the Ardennes as much as three or four miles."

Could you find space to inform me by what reasoning or on what data geologists arrive at such a conclusion, and whether it is considered that the level of the surrounding district was raised in a corresponding degree, or that the Mendips were isolated mountains, somewhat like the Peak of Teneriffe, rising abruptly from the plains below?

INQUIRER

P.S.—Perhaps by inserting this letter and reply you may convey information to others as well as myself.

Segmentation of Annulosa

MR. RAY LANKESTER, in his letter on "The Segmentation of Annulosa" in NATURE of the 4th ult., appears to maintain that there is no fundamental difference between the segmentation of annelids and that of chitons. He says of the latter, "Why should there not be segmented molluscs?" I can no more answer this than I could answer the question why there should not be hexapod vertebrates. There is nothing impossible or absurd in the idea of the segmentation of chitons being essentially similar to that of annelids; the question is whether it is really so. He says, "The larva of a chiton is (in appearance) identical with that of an annelid, and its segmentation makes its appearance in the same way." This is an important argument, but not conclusive. If, as I believe, Mr. Spencer's theory of the origin of the annulosa is true, the segmentations of the two are fundamentally distinct phenomena, and it might appear that their development should be unlike. According to that theory, the segments of the ancestor of the annulosa had their origin by budding backwards from the head; while the segmentation of the chitons has from the first been "superinduced" like that of the spinal column of vertebrates. But it is admitted that the annulosa do not in their actual development show decided traces of this origin. I think, however, this last fact may be explained by a principle which Mr. Spencer lays down somewhere, with great probability, as a general law (though of course it is a law of tendency only, and may be subject to exceptions), namely, that there is a general tendency to the substitution of direct development for indirect. Thus, the segments of annulosa may have been originally formed one after the other by budding backwards, and yet may now be formed simultaneously, or nearly so, by the segmentation of a vermiform larva.

The opinion that the two cases are distinct is, I think, very strongly confirmed by the fact that annelids still propagate by budding off young annelids from their tails, while no mollusc whatever is known to do so.

JOSEPH JOHN MURPHY

Brittany Dolmens and Tumuli

IN NATURE for May 2 Captain Oliver advocates the theory that dolmens are merely the skeletons of original chambered tumuli. This, I think, scarcely agrees with the fact to be observed in the principal dolmens and tumuli of Finistère. In most cases in that department the dolmens occupy situations in every respect similar to those in which the tumuli are found, so that meteorological, and, indeed, every other but human agencies, must have affected both in the same manner and degree. Notwithstanding this, the dolmens are invariably bare, and the kists are as constantly covered—there are no signs of even incipient degradation and denudation in the latter, and none of former covering in the first. It would be unwarrantable to suppose that had the dolmens been uncovered by human beings, no vestiges of the mounds would remain, or that, this perfect and unaccountable removal of material being allowed, the skeleton, *i.e.*, the part containing the most useful stones, should be left unscathed.

There is, however, a more important point of difference between dolmens and the barrow kists; namely, that in the chambered tumuli there is almost always present a floor-stone—a part of the structure which I have never seen at the base of any of the dolmens of the region in question. And there can, in their case, be no chance of removal, as the floor stone would necessarily be the last to remain in its place. The dolmens, again, as a rule, were evidently erected with no attempt at nice adjustment of the sides or top, whereas tokens of some care and trouble are to be found in the way in which most of the entombed kists are built.

In these remarks I have limited my observations to those dolmens and covered chambers which are of the simplest grade, but they would, I think, be equally applicable to the more complicated structures similarly circumstanced. It seems, therefore, premature to apply the term "dolmen mound" to such barrows as Carnoët, for instance, where the small and accurately-made kist bears no resemblance to the frequent dolmens of the district.

Harbottle, Rothbury, May 4 G. A. LEBOUR

The University of Freiberg

MAY I be allowed to ask in your pages for information about the University of Freiberg in Saxony as a place of instruction in Geology, Mineralogy, and Chemistry? I should also be glad to know which German Universities are held to be the best for learning these three subjects, and when their terms end. Any information on these points will oblige,

Cambridge University, May 5 UNDERGRADUATE

Sources of Sandstone

YOUR geological readers will readily admit the importance of any hint that will assist them in determining the source from which a particular bed of sand or sandstone has been derived.

How to discriminate between sand produced by the breaking-up of quartz, and sand produced by the breaking-up of flint, does not appear to be generally understood. Chemical analysis gives no assistance; and when examined microscopically by ordinary light, no difference can be detected.

Polarised light, however, differentiates these two substances in such a decided way, that where they alone are concerned, no doubt can remain for an instant as to whether a grain of sand consists of one or the other. The quartz, as of course everybody knows, is resplendent with prismatic colours, while the flint shows a cold steel-grey surface covered with a peculiar marking, which I am obliged to call a species of reticulation for want of a term more exactly descriptive. This marking I consider to be indicative of something in the structure of the organism replaced by the flint. When once seen it is easily recognised. Some species of chert, that from the Portlandian beds for instance, show the same marking as flint.

I may also add that polarised light shows chalcedony to be, like quartz, a crystalline instead of a non-crystalline substance, as usually taught. It bears the same relation to quartz crystals and massive quartz as fibrous gypsum does to selenite and common gypsum. M. HAWKINS JOHNSON

Polarised Light

WE have all noticed that when the sun shines directly through a window hung with figured muslin curtains, the reflection of the pattern of the curtains in the window interferes with the prospect.

When this reflected image is viewed through a Nicol's prism it disappears when the prism is rotated, leaving the prospect unobstructed; the experiment is very interesting, and can be performed by any one who has a polariscope attached to a microscope, and it is only necessary to observe that the image is viewed at the proper angle. The effect will possibly be best when the sun's rays make an angle with the curtains and the glass nearly coinciding with the polarising angle. (In my case the angle was 36° 52′.)

Tyndall has mentioned a case in which the haze obstructing the view of a mountain-top was rendered transparent by the Nicol.

The readers of NATURE have probably observed how completely the leaves of the ivy polarise light; viewed through the Nicol and a pink selenite, the plant appears covered with blossom.

R. S. CULLEY

CHOLERA AND SUN-SPOTS

ON Friday evening, the 26th ult. Mr. B. G. Jenkins, of the Inner Temple, read before the Historical Society a remarkable paper on Cholera, founded on a communication to the Russian Imperial Academy of Sciences, and now under the consideration of the Medical Council of the Minister of the Interior. The author of the paper maintained that no true advance could be made in any science founded on experience, and looking to facts for its development, until the history of that science had been recorded and correctly interpreted; and that it was, because we have been looking at the facts of cholera, which have been accumulating for half a century, as facts without attempting to show, or rather without succeeding in showing, in what relation they stand to each other, that we are really no wiser than we were forty years ago.

He held that, instead of one "home" of the cholera in the delta of the Ganges, there are seven, all situated on or near the Tropic of Cancer, equally distant from each other, of which the most important is that at the mouth of the Ganges; the others are to the east of China, to the north of Mecca, on the west coast of Africa, to the north of the West India Islands, to the west of Lower California, and among the Sandwich Islands; that a reference to the map would show that the recorded appearances of cholera over the globe may be satisfactorily explained by supposing seven atmospheric streams, each 1,400 miles in breadth, to proceed from these foci in a north-westerly direction; and that at some periods, as 1833, 1850, and 1866, nearly all the streams were in activity.

Having pointed out the course of these streams on a map especially prepared, and shown how the disease moved within the limits of each, in both the north-west course and its south-east extension across the Equator, the author, in tracing in detail the course of the cholera in India during 1817 and 1818, called attention to a remarkable law which manifested itself, a law which he held was generally applicable wherever cholera appeared.

Although the course of cholera during 1817 was not very clear, still it is evident that it was north-west and south-west. The lull in virulence and advance which occurred in December 1817 continued to March 1818, when cholera broke out again just where it had ceased the previous December. He drew attention to a very recent similar instance: the cholera last year halted on the western border of Russia, and about a fortnight ago broke out in Poland, which augurs ill for the North of England this year. The remarkable law which the author pointed out was that in 1818 the cholera advanced simultaneously in two directions, north-west and south-west, in such a manner that all the places attacked at any given time by its north-west advance were situated at right angles to all the places attacked at the same time by its south-west advance. This double advance is made evident by cutting a piece of paper square, placing a corner upon the map at Calcutta, and moving it across India in a direct line to Surat. In 1819 the cholera crossed the Arabian Sea to Muscat, and passed simultaneously through Persia, and up to 1823 advanced as far as Asia Minor and the Caspian, and then died out. In 1823 a fresh outbreak occurred in India; this steadily proceeded to the north-west, and halted in the west provinces of Russia in 1830, and the next year broke out in full force in the same locality, thus presenting a parallel to 1871-2, and went as far as Britain. By referring to the map it will be seen that all places attacked by this stream of cholera in 1831 lie within the boundaries represented by two lines, one drawn from the southern point of India to the north of England, and the other from the Ganges through Orenburg to Archangel. The author having described with great minuteness the rise and progress of the other six streams, bringing the subject down to the present day, stated that Europe was liable to attacks from two great sources, India and Arabia: Russia and Northern and part of Central Europe coming under the influence of the Indian stream; Southern and Western and part of Central Europe under the influence of the Arabian; and that the Continent would certainly be attacked by both this year. The curious cases of ships at sea being suddenly attacked by cholera, and, again, the instances of ships sailing along the coast of India being struck by the disease when at the same place, he explained on the supposition that they had been sailing within the limits of the cholera streams; for when they got outside the limits the disease suddenly ceased. He called attention to a fact worthy of mention, that all the places recorded by Dr. Gavin Milroy as unaffected hitherto by cholera lie

outside these streams, or in their possible, but not actual, extension.

Having stated that he was prepared to give, in another paper on the origin of the disease which he was preparing, an ample explanation of some well-known points about cholera; such as its partial connection with the east wind, its following the course of large rivers, its greater prevalence on tertiary strata, alluvial tracts, and the deltas of rivers, and its comparative rarity on secondary and primary strata, the author proceeded: "It was not my intention at the present time to enter into the question of the origin of the disease; but having read a few days ago that Dr. Buchanan in this very hall congratulated the meeting on being able to number among the things of the past the time when the propagation of cholera was supposed to be due to all manner of cosmic and atmospheric influences, and on having 'reached a solid basis of fact and knowledge upon which further observation might be built with security,' I am tempted to declare that I for one maintain that this despised theory, which Dr. Buchanan fancies is buried and put out of sight, is the correct one. I maintain that cosmic influence lies at the origin of cholera—that cholera is intimately connected with auroral displays and with solar disturbances. I believe that I am able to show that a remarkable connection exists between the maxima and the minima of cholera epidemics and of solar spots; and in directing your attention to this map, on which I have represented graphically the amount of cholera and the number of sun-spots for the last fifty years, I wish to show that there is here also 'a solid basis of fact and knowledge upon which further observation might be built with security.' You are all probably aware that the great astronomer Schwabe discovered that the sun-spots have what is called a ten-year period; that is, there is a minimum of spots every ten years. It was also discovered that the diurnal variation in the amount of declination of the magnetic needle has a ten-year period. The same was proved in regard to earth currents, and also auroræ. The maxima and minima of the four were found to be contemporaneous. This was a great result; but Professor Wolf, on tabulating all the sun-spots from the year 1611, discovered that the period was not ten years, but 11·11 years. This period is now the accepted one for the sun-spots, and it has been established for the magnetic declination, and by Wolf for the auroræ. Now, it is a curious fact that the last year of every century, as 1800, has a minimum of sun-spots, so that the minima are 1800, 1811·11, 1822·22, 1833·33, &c. The maxima do not lie midway between the minima, but anticipate it by falling on the year 4·77 after a minimum; for example, 1800 was a minimum year, then 1804·77 was a maximum year. Now, cholera epidemics have, I believe, a period equal to a period and a half of sun-spots. Reckoning then from 1800, we get as a period and a half the date 1816·66, which was shortly before the great Indian outbreak; another period and a half gives 1833·33, a year in which there was a maximum of cholera; another, 1849·99, that is, 1850, a year having a maximum of cholera; another, 1866·66, a year having a maximum of cholera; another, 1883·33, as the year in which there will be a cholera maximum. It follows from what has been already said that 1783·33 would be a year in which cholera was at a maximum. Now it is a fact that in April 1783 there was a great outbreak of the disease at Hurdwar.

"I would call attention to the parallelism of increase and decrease of these curves. I am not, however, prepared to say that sun-spots originate cholera; for they may both be the effects of some other cause, which may indeed be the action of the other planets upon the earth and upon the sun. If that be the case—and I see no reason why it should not—we may then have an explanation of the minor periods and of the large period of 56 years, which Wolf believes he has detected, and also of the minor periods observed in cholera-epidemics.

"My own opinion, derived from an investigation of the subject, is that each planet, in coming to and in going from perihelion—more especially about the time of the equinoxes—produces a violent action upon the sun, and has a violent sympathetic action produced within itself—internally manifested by earthquakes, and externally by auroral displays and volcanic eruptions, such as that of Vesuvius at the present moment; in fact, just such an action as develops the tail of a comet when it is coming to and going from perihelion; and when two or more planets happen to be coming to or going from perihelion at the same time, and are in, or nearly in, the same line with the sun—being of course nearly in the same plane—the combined violent action produces a maximum of sun-spots, and in connection with it a maximum of cholera on the earth. The number of deaths from cholera in any year—for example, the deaths in Calcutta during the six years 1865–70—increased as the earth passed from perihelion, especially after March 21, came to a minimum when it was in aphelion, and increased again when it passed to perihelion, and notably after equinoctial day; thus affording a fair test of my theory."

ON THE DEPTHS OF WATER IN WHICH WAVES BREAK

OBSERVATIONS MADE AT SCARBOROUGH IN 1870

As the force which different sea-works have to resist varies with the height of the waves that reach the coast line, any data which will enable the marine engineer to predict this height when designing such works must obviously be of importance. In the *Edinburgh Philosophical Journal* for July 1852, I stated, as the result of experiments made in 1850 on a small fresh-water loch, and afterwards on larger sheets of water, that the height of the waves increased most nearly in the "*ratio of the square root of their distances from the windward shore*," or, in other words, *the crest of the wave as it increases in height describes a parabolic curve*. So that, if h = height of wave, d = distance, and a is a coefficient varying with the strength of the wind, $h = a \sqrt{d}$. For most practical purposes of the engineer, the coefficient a may for heavy gales be taken at one and a half; so that the formula becomes—

$$h = 1{\cdot}5 \sqrt{d},$$

where h represents the height of the wave in feet, and d = length of exposure in miles.* As elsewhere stated,† this formula becomes for short distances—say for under ten miles—

$$h = 1{\cdot}5 \sqrt{d} + (2{\cdot}5 - \sqrt[4]{d}).$$

The height of the wave, however, which reaches any particular work, is not necessarily that which is due to the line of exposure; for the shallowing of the water near the shore may cause the heaviest waves to break, either partially or wholly, before they reach the work. Mr. Leslie found that at Arbroath Harbour the works were not so severely tried by the very heaviest class of waves as by others of lesser size, which were not *tripped up* by the outlying rocks. The same effect has also been observed at the river Aln, where the smaller waves occasion a greater "range" in the harbour than the larger ones which break in passing over the bar, and are thus reduced in height. The larger waves are not, then, always so destructive as the smaller. It becomes, therefore, a question of some moment to determine the maximum height of wave that is possible in a given depth of water.

Mr. Scott Russell, whose contributions to what may be

* Mr. Hawkesley, in the "Proceedings of the Institute of Civil Engineers," gives a formula which is satisfactory so far as it corroborates the law of increase which I had stated in the *Edinburgh Philosophical Journal* in 1852; but he employs a coefficient which gives much greater results than my experience warrants.

† "The Design and Construction of Harbours," by Thomas Stevenson, F.R.S.E. (Edinburgh, 1864: p. 22).

called the marine branch of hydrodynamics are of such great value, has stated that "he has never noticed a wave so much as 10ft. high in 10ft. water, nor so much as 20ft. high in 20ft. water, nor 30ft. high in five fathoms water; but he has seen waves approach very nearly to those limits." Mr. Russell has not stated whether the depths of water referred to are those below the trough of the sea or below the still-water level. In my book on "Harbours" I gave three observations on short waves from 2ft. 6in. to 3ft. high, which corroborated Mr. Russell's statement, supposing him to refer to the depth below the hollow. But since that time I had an opportunity, during a N.E. swell in July 1870, of observing the depths in which waves of a larger class broke at the Promenade Pier at Scarborough, where the heights could be measured with very considerable accuracy on the iron piles and open sloping slip or grating at the seaward end of the pier; and the following are the results:—

Heights of waves from hollow to crest.

′	″
5	6
5	0
5	0
5	6
5	3 = mean height.

The mean depth of water below the trough was 10ft. 3in.

Heights of the highest waves from hollow to crest.

′	″
6	0
6	0
8	0
6	0
6	0
6	6 = mean height of highest waves.

The mean depth of water below the trough was 13ft. 8½in. So that in both cases those waves did not follow Mr. Russell's law, but *broke when the depths below their troughs were about twice their own height.*

It must not be supposed, as is generally believed, that the height of the crest above the mean level of the sea is equal to the depression of the trough below that level; for Prof. Rankine has lately shown that this is not the case. When L = length of wave, H = height from trough to crest.

$$\text{Crest } above \text{ still water} = \frac{H}{2} + \cdot 7854 \frac{H^2}{L}.$$

$$\text{Trough } below \text{ still water} = \frac{H}{2} - \cdot 7854 \frac{H^2}{L}.$$

These formulæ, he states, are exact only for water of considerable depth as compared with the wave's length.

Edinburgh THOMAS STEVENSON

CYCLONES IN THE INDIAN OCEAN

SEVERAL cyclones have passed Mauritius since the latter part of January. From the 24th to the 30th of that month the barometer at the Observatory fell from 29·888 to 29·708 inches, with the wind squally from E. At 10 A.M. on the 30th it was intimated to the newspapers that there were "indications of a hurricane approaching the island;" but at 2 P.M., the wind having in the interval veered to N. of E, it was announced that there was "little danger."

This storm was encountered by the schooner *Emily*, on her passage from Tamatave, from Jan. 29 to Feb. 1. At the commencement of the gale, she was in 19° 31′ S., and 53° 30′ E. The wind veered from N.E. to E., S.E., S., S.W., W., and N.W., with a "tremendous sea and torrents of rain," and the lowest reading of the barometer on board was 29·00 inches. The vessel escaped with the loss of only a few sails.

The storm then curved to the S. and E, and was experienced by the barques *Gladiateur* and *Abbotsford* on Feb. 2 and 3, in 31° to 29° S., and 54° to 55° E. With the former vessel the wind veered from E. to N.E. and N., blowing at one time with great violence. The barometer at 8 A.M. on the 2nd was at 28·80, and the wind from E.N.E. The *Abbotsford* had the wind from the same direction, and her barometer was at 28·40 at 5 A.M. on the 2nd. Both vessels had a "tremendous sea and torrents of rain," and they lost sails and bulwarks.

On Feb. 5 the barometer at Mauritius, after rising to 29·790, again began to fall, and on the 7th was at 29·606. The wind was squally from S.E., and it veered to S. by W., from which point there was a gentle breeze at 9.30 P.M. on the 7th, with fine clear weather.

At 10 A.M. on the 7th it was announced that "the weather of the last two or three days indicated the passage of another storm, which then broke between E.N.E. and E.;" and at 10 A.M. on the following day that "the storm had curved to the S. and S.E."

This storm was encountered by the barque *Elizabeth*, from Melbourne to Mauritius, on the 7th and 8th, in 20° 16′ S., and 68° E. The wind was strongest from E.N.E. to N.N.E, and the lowest barometer was 29·20. There were "torrents of rain." By standing back to the E. the *Elizabeth* avoided all danger.

On Sunday, Feb. 11, the barometer at the Observatory, after rising to 29·870, again began to fall, with the wind squally from S.E., and the weather fine. During the 12th it fell ·060 inch, and ·090 inch more during the 13th, with the wind still squally from the same quarter. At 10 A.M. on the 14th the following notice was sent to the newspapers:—"A hurricane since the 11th. It now bears about E.N.E. of us. There are some signs that it will pass to the E. and S. of the island, but there is danger." The barometer still falling, and the wind increasing to strong breezes from S. by E. to S.S.E, at 3 P.M. a telegram was sent to Port Louis (6 miles off), stating that "the centre of the hurricane was about 350 miles to the E.N.E., and approaching the island," and soon afterwards storm signals were hoisted at the railway stations. The barometer at 3 P.M. stood at 29·612, and the wind, which was then S. by E, was blowing with an estimated force of 2·5lbs. on the square foot.

At 9 A.M. on the 15th the barometer was at 29·478, with a strong gale from S.E., and it was estimated and announced that the "centre of the storm bore about N.N.E. 150 to 200 miles, and that it was still approaching the island." At 3 P.M. the wind being from E.S.E. to E. by S. in increasing gales, and the barometer at 29·382, it was telegraphed to Port Louis that "the centre was about 150 miles to N. by E., and that it would probably pass, with an increase of wind, to N.W. and W. of the island, without doing much damage."

During the night the wind increased considerably from E.S.E. to E. by S., and the barometer attained its lowest reading (29·328) at 1 A.M. on the 16th; but the mercury was oscillating, being at 2 A.M. at 29·356, and at 3 A.M. 29·330; and the time of the greatest depression of the mercury, as shown by the barograph (at the Magnetic Observatory, three miles off) was 2.40 A.M. At 9 A.M. the barometer was at 29·440, with the wind at E. to E. by N., and it was announced that "the centre bore N.N.W., and that there was no danger."

The barometer then continued to rise, until, at noon on the 18th, it was at 29·682, with a moderate breeze from N.E.

It is worthy of remark that the wind never went beyond N.N.E., but gradually backed to East.

This storm was more or less encountered at sea by the *Harpesia, Gryfe, Oleander, St. Germaine, Misser, S. S.*

Danube, *Staffordshire*, *William Fairbairn*, *Pendragon*, *Odalisk*, and *Paolo Revello*, some of which suffered severely.

At 5 A.M. on the 15th, the *Staffordshire*, in about 18 30′ S. and 61° E., was thrown on her beam ends, and in great danger of foundering. The *William Fairbairn*, a fine iron vessel of 1,293 tons, lost all her masts and sails, and had her decks almost completely swept. On the 13th, in 19° 2′ S., and 64° 40′ E., she had a strong gale from S.E., which increased to a hurricane. About 7 P.M. her barometer was at 28·70, and early on the 14th the wind shifted from S.E. to N.W. The *Paolo Revello*, on the 14th, in 18° 8′ S. and 61° 54′ E., was completely gutted. The captain's papers and log-book, cabin furniture, &c., together with the chief officer and nine men, were washed overboard.

From the logs hitherto received it appears that the storm was formed between the S.E. trade-winds, and the N.W. monsoon from the 7th to the 9th. On the 10th the centre was in 13° 10′ S. and 78° 30′ E.; on the 12th in 15° 6′ S., and 71° 34′ E.; on the 14th in 17° 15′ S., and 63° 28′ E.; on the 16th in 20° 7′ S., and 55° 50′ E.; and on the 18th in 22° 15′ S. and 51° 50′ E. During the first six days it travelled on a W.S.W. course, and then curved a little towards the south. It passed about 165 miles north of Rodrigues at noon on the 14th, about 65 miles north of Mauritius early on the 16th, and N.N.W., &c., of Reunion from noon on the 16th to noon on the 17th. Its average rate of progression was nine miles an hour, and the area over which the wind blew from strong breezes to hurricane violence was about 800 miles.

The fact that in this, as in other storms, the wind at Mauritius did not veer more than twelve points, seems to be explained by the incurving of the air towards the centre.

On the evening of the 15th, or morning of the 16th, seventeen vessels put to sea from the roadsteads of Reunion, and their fate is not yet known. If they held to the N.W., with the wind from S.E., they probably got into the heart of the storm.

CHARLES MELDRUM

Mauritius, March 8

P.S.—The aurora seen here on the night of the 4th to 5th February, was also seen at sea by several vessels. Here are extracts from their logs :—

Olive Branch in 27° 47′ S. and 59° 48′ E.—"At 10 P.M. the sky became very red and fiery—southern lights."

Abbotsford in 30° 9′ S. and 56° 10′ E.—"Dull atmosphere. Aurora australis reflecting brightly in the south, giving light over all the ship. Clouds tinged with deep red."

Elizabeth in 20° 33′ S. and 78° 3′ E.—"At 10 P.M. Aurora australis unusually bright."

Gladiateur in 30° 32′ S. and 57° 28′ E.—"At 8 P.M. a red and yellow and strange looking sky. Midnight, sky the same."

Pendragon in 13° 43′ S. and 84° 13′ E.—"At midnight very suspicious-looking weather to the S., the sky being quite red."

William Fairbairn in 32° 57′ S. and 60° 2′ E.—"At 10 P.M. looking ugly, and meteorological signs of a hurricane. Midnight same, and up till 3 A.M. when it cleared off."

Caton in 31° 31′ S. and 108° 10′ E.—"Midnight, red sky, like fire to E.S.E."

Oleander in 38° 26′ S. and 31° 53′ E.—"From 7.30 to 11.30 P.M. the sky was illuminated with a very brilliant Aurora australis."

There is little doubt that the suspicious-looking weather to the S., seen by the *Pendragon* in about 14° S., was the aurora. Captain McKenzie of the *W. Fairbairn* reports that his standard compass was affected to the extent of ¾ of a point, and his other compass to the extent of two to three points. C. M.

PHYSICAL SCIENCE IN GLASGOW UNIVERSITY

THE Physical Laboratory of Glasgow University, which till quite lately was the only one in this country, dates from the year 1852. It was with difficulty that room could be found for a laboratory of any kind in the old building; but in the new building, of which this is the second year of habitation, considerable space has been set apart for Experimental Natural Philosophy.

At present six rooms belong to the department, exclusive of the Professor's private sitting-room and the store-rooms, and on the completion of the tower, which is not yet finished, additional rooms will be devoted to it. The whole suite of rooms is arranged so as to be in direct communication with those of the professors of mathematics, engineering, and astronomy.

The chief lecture-room is 42ft. long by 35ft. broad, its side windows look nearly north and south, and over the lecture table there is a glass-covered turret, or louvre, the top of which is 40ft. from the floor. The windows of the room are completely darkened with the greatest ease by means of double curtains of blue baize, an inner and an outer curtain for each window, and these can be unfurled and furled at a moment's notice; two baize screens, one below the other, are drawn across the base of the louvre. The room is ventilated, as are all the rooms in the new University building, on Mr. Phipson's plan. Pure air is drawn down a shaft in the tower by fanners, which are worked by a small steam engine. The air is passed through a dry chamber, containing hot water pipes, and is then driven mixed with any quantity of fresh cold air that may be required, into the class-room. It enters at the top of the room, and the used air is drawn off through passages below the floor.

Benches are arranged for about 150 students. They are not on a level, but rise at an angle of 25°, and beneath them there is a large convenient space, with shelves for 50 or more cells of Daniell's battery, which I shall describe immediately.

Of the other five rooms one is an additional lecture and experiment room, one is the general laboratory, one is the principal apparatus room and museum, and the remaining two are used for storing apparatus and for occasional experimenting. The laboratory is on the ground floor, and is below the lecture-room, which is on the second story. It is a room 52½ft. long by 34ft. broad. It has six windows, three looking north and three looking south, and these can be darkened like those in the lecture-room by means of drop curtains of baize. Three quarters of the floor is wood, the remainder concrete, covered with Portland cement; but in order to get perfectly steady tables, piers of masonry, built on the foundation, rise through the floor, and on them the feet of the tables rest. The flooring does not touch the piers at all, and thus, however much the floor may shake, the table remains comparatively steady. This arrangement gives far greater steadiness than a complete stone floor. Besides these piers there are two somewhat larger stone constructions, which are also unconnected with the flooring; one of these is intended for a large steady table; and on the other there is a massive stone erection (Fig. 1), on which is to hang a pendulum for a clock, or for experiments on the force of gravity. It is intended that the point of suspension of the pendulum shall be perfectly free from vibration.

Some of the tables are ordinary working tables On others, instruments such as the electrometer and electrodynamometer are set. Below the table there are frames for supporting 500 cells of a constant Daniell's battery, which were in use in the old college, and a great part of which are now re-charged.

In one corner of the room there is a wooden enclosure, which is fitted up as a small chemical bench. The ordinary reagents and apparatus for chemical testing are thus at hand.

There are large gas holders, each holding eighteen cubic feet of gas, in the laboratory. The construction of the gas-holders is the same in principle as that used in ordinary gas works. Each is, in fact, a large copper bell, with its mouth dipped under water in a deep tank. All the stop-cocks connected with the gas-holders are kept constantly enclosed in vessels full of water, in order to prevent leakage. The holders are filled at the beginning of the session, one with oxygen and the other with hydrogen, and the lime light is thus always ready.

With this brief account of the general arrangement of the premises, I shall now describe more particularly some of the apparatus and conveniences of the lecture-room and laboratory, and some of the experimental investigations going on at present.

The lecture-table in the lecture-room is 26ft. long by 2¾ft. It is not straight, but made of three pieces, so as to be concave on the lecturer's side. A portion of the top of the table is removable; and when it is taken away a large trough suited for showing waves in water, and for other hydrodynamic experiments, is exhibited. The trough is as long as the table, and is 14in. broad and 12in. deep. It opens out at one end

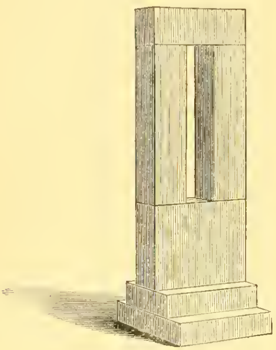


FIG. 1

into a tank 26in. broad and 20in. deep. The lecture-table is, of course, furnished with the usual supply of coal, gas, and water; and besides pipes, which give hot water and steam, are led to it. These pipes come from the boilers that heat the air with which the University buildings are warmed and ventilated. Pipes are also led to the table from the oxygen and hydrogen gas holders in the lower laboratory, so that the oxyhydrogen light is always at command at a moment's notice; and it is found a great convenience to have it so. It is used very frequently, and enables us to show to a large class many experiments which we could not attempt without it—experiments, for instance, with the reflecting galvanometer and electrometer. The preparation for such experiments generally requires much time and trouble; but with the permanent gas-holders filled once for all at the beginning of the session and always ready, the oxyhydrogen light gives less trouble than an ordinary oil lamp.

A powerful battery, which I shall have to describe immediately, is always ready. Very thick electrodes, consisting of nine ply of No. 16 copper wire of high conductivity, plaited together, pass from binding screws on the lecture-table to the battery below the lecture-room seats, and thence down to the lower laboratory.

For instruments that require a very steady support there are two pillars, one at each end of the lecture-room table. These are unconnected with the flooring. They pass through it without touching the boards, and rest on the stone arches that cover a gateway beneath.

On each side of the lecture-room there is a clock. One of them is governed by electricity on Jones's principle; the other is an electric clock by Bain, and has a current from a single cell for its motive. The former is an ordinary eight-day clock, and is regulated in the following way:—The bob of the pendulum is a hollow coil of insulated wire. The plane of the coil is perpendicular to that of the motion of the pendulum. The ends of the coil are carried up the pendulum rod, and are connected with telegraph wires which proceed from the Observatory of Glasgow University. Fig. 2 gives a front view of the pendum, and shows the coil and a pair of permanent magnets pointing towards the coil. When the pendulum swings the hollow coil passes over the end of the magnet at each side. Fig. 3 shows the suspension of the pendulum, which consists of two flat springs, to which the wires coming up the pendulum rod are joined. The springs are attached to insulated brass pieces, to which are connected, by means of binding screws, the wires from the Observatory. There is a clock in the Observatory which is constantly kept right, and by means of a make-and-break arrangement connected with its pendulum, a galvanic cur-

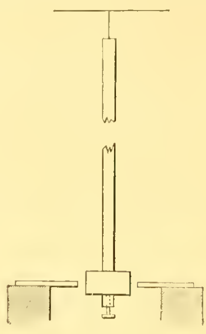

FIG. 2

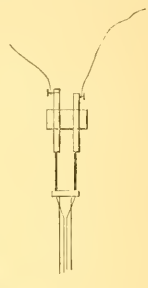

FIG. 3

rent is sent once in each second through the wire that proceeds from the Observatory, and thus through the coil at the extremity of the pendulum of the clock that is to be controlled. The coil is thus once in each second converted into a temporary magnet, and is attracted and repelled by the permanent magnets between which it swings. It will be readily understood that with this arrangement a clock that is going slightly too slow may be accelerated a little, and a clock that is going slightly too fast may be retarded a little, at each passage of the current. To be able to set the controlled clock to agree with the Observatory clock, it is necessary to have some way of distinguishing one second from another. This is done by means of a galvanoscope or indicator, which is included in the circuit, and which beats seconds with the currents. The instrument is placed close to the clock in a place convenient for comparison of it and the seconds hand of the clock. It is arranged that there shall be no beat on the last second of each minute; and that in the last minute of each hour there shall be an interval of twenty seconds without any current. Thus the ends of the minutes and the ends of the hours are distinguished.

Of mechanical apparatus almost daily employed for lecture illustrations may be mentioned various kinds of vibrators, weighted spiral springs, a Coulomb's torsion vibrator, a cycloidal and a common pendulum arranged for comparison, a friction brake, &c., &c. Over the lec-

ture-table there is suspended from the top of the louvre already mentioned a pendulum, which is intended to show the rotation of the earth. The length of it is 38 ft.; and it thus executes one complete vibration in rather less than seven seconds. In showing the rotation of the earth by Foucault's method, everything depends on perfect symmetry in the suspension of the pendulum. The suspension used here is quite new, and, I think, will prove satisfactory. I hope to take an opportunity of describing it hereafter, when I can make a statement as to results obtained.

I believe that every one who has ever had to work in a laboratory with a large battery has felt how much a powerful and constant cleanly and easily managed battery is wanted. A dozen batteries have been invented, and some of them patented within the last two or three years. Most of them are only fit for such purposes as ringing an electric bell for an instant, and even at such work as that they do not last long, and not one of them is even tolerably constant, though constancy is pretended for almost all. What is wanted is a battery that will remain constant for six months or a year without more attention than that of occasionally wiping the outsides of the cells, and replenishing them with some salt or acid and with water; and which is powerful enough for an electric light or for any other class experiment. Freedom from acid fumes is also in most laboratories an essential. A great many experiments have been made here with the view of getting such a battery as I have described, and at last, as we hope, with some success.

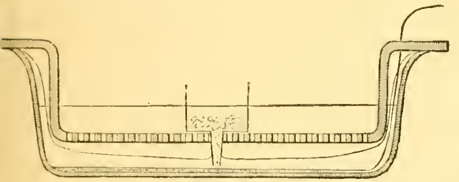

Fig. 4

Since the invention of Grove's battery, that and Bunsen's modification of it have been almost exclusively used for the electric light. These, as far as high electromotive force and smallness of resistance are concerned, are preferable to any other; but there are great objections to the use of them in the necessity for discharging them frequently, and in the emission of acid fumes, which cannot but be injurious to the person who discharges the battery, and which are very destructive to apparatus unless the battery be kept in a special chamber. The battery which we are employing in Glasgow, and which gives great promise of being really successful, is a modification of Daniell's battery.

Sir William Thomson described (Proc. R. S., Jan. 1871, quoted in NATURE of Feb. 2, 1871) a gravitation battery, in which advantage is taken of the fact that water saturated with both sulphate of zinc and sulphate of copper is denser than either saturated solution of sulphate of zinc alone or sulphate of copper alone. A horizontal copper plate being put at the bottom of the cell and a plate of zinc near the top, the cell is charged with saturated solution of sulphate of zinc, and crystals of sulphate of copper are placed in a funnel, whose delivering tube passes down to the bottom of the cell. The superior density of the solution containing sulphate of copper in addition to the sulphate of zinc, is that which keeps the sulphate of copper from surrounding the zinc plate and attacking it. This arrangement, if the sulphate of copper travelled towards the zinc solely by diffusion, would have great advantages over any in which the zinc and copper plates are placed vertically, and a porous separator is used.

It was thought that the form of cell described then would turn out admirably, and it is excellent in many ways; but it was found that a constant evolution of hydrogen takes place at the copper plate, bubbles rising perpetually from it. These cause so much stirring up of the solutions that sulphate of copper is carried rapidly up to the zinc plate, and both eat the zinc away, and it is itself wasted in depositing copper on the zinc plate. The reason of this bubbling appears to be that particles drop from the zinc on to the copper plate, and, forming small circuits there, send up hydrogen bubbles through the liquid. We have now done away with the difficulty in the following way, and we have got a cell which, so far as we have been able to test it, promises to be in all respects satisfactory. The under surface of the zinc is now covered with a sheet of parchment paper (known as manilla) the edges of which are brought up round the zinc, so that it is enclosed in a porous cell of this material. The paper, while it does not add sensibly to the resistance of the cell, acts most beneficially by hindering the particles which drop off the zinc from falling on to the copper plate; and if there are any bubbles rising from below, it prevents them from bringing sulphate of copper up to the zinc plate.

We are now employing two kinds of cells, and have forty of each kind in action. The first is very similar to that described by Sir W. Thomson in the paper already referred to. The cell is of glass (Fig. 4); and this is an advantage, as the condition of the solutions and metals which it contains may be seen at any time. It is a circular pan* with a flat bottom The diameter is 21 inches. A disc of thin sheet copper is laid on the bottom; and a thick copper wire covered

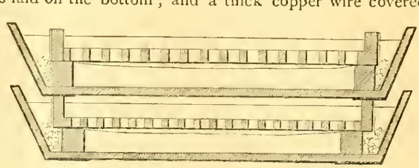

Fig. 5

with gutta percha is soldered to the copper disc and rises to the top of the cell as an electrode. In the upper part of the cell is a heavy mass of zinc, cast into the form of a circular gridiron, with three ears or projections which rest on the edges of the glass. The gridiron shape is adopted in order to permit the hydrogen, which we find constantly being liberated, to escape. The distance between the zinc and copper plates is about 2½in. A large sheet of parchment paper covers the under side of the zinc, and the corners and edges of the paper are brought up round the vertical sides of the zinc so as to form a kind of bag round it. The parchment paper is thus a separator between the mass of liquid in the cell and that immediately surrounding the zinc. There is a circular hole in the middle of the zinc, and the tube of a glass or earthenware funnel passes through this and through a hole in the parchment paper, the edges of which are tied round the tube, down to the bottom of the cell. The cell is then filled up with saturated solution of sulphate of zinc till the level of the liquid is higher than that of the top of the zinc; and on the top of this a layer of pure water two or three inches deep is poured carefully, so as to avoid mixing. The pure water forms an atmosphere into which the sulphate of zinc formed during the action of the battery may diffuse, and thus crystallisation is avoided. To set the cell in action crystals of sulphate of copper are put into the funnel just described. The dense solution

* The pans that we are using are, I believe, made by glass-blowers for milk pans. They are inexpensive, and answer excellently. To make the bottom horizontal we cover it with sand moistened with saturated solution of sulphate of zinc, and carefully level it by comparison with a little of the liquid lying on the top. It is essential to have it level if we wish to use up all the charge of sulphate of copper, as described in the text, to the best advantage.

flows down over the copper plate at the bottom, and in less than five minutes the cell is in full work.

We have at present forty cells such as I have just described. The average resistance of one cell is 0·19 of an Ohm. The electro-motive force of a Daniell's cell is 1·07 Volts.

The second form of cell is of the following construction. A shallow wooden tray, square, and with slightly slanting sides, is lined with sheet lead; and this, after being electrotyped with copper, forms both the containing vessel for the liquids and the copper plate of the cell. Copper trays were used at first, but they were soon eaten through by the solution. The lead is not attacked at all. The length of a side of the lead tray is 21in., and its depth is 3¾in. In each corner is set a small block of wood 1¼in. high. The zinc plate, which is like a square gridiron, rests at its corners on these blocks. The zinc has parchment paper tied round its lower surface and sides. The cell is filled up with saturated solution of sulphate of zinc, and crystals of sulphate of copper are dropped in when required round the edges outside the parchment paper. For connecting these cells together in series, the lead lining is carried over the wooden tray at the corners and down the outside to the under surface of the bottom of it. Here it is soldered to a small square of thick sheet tin. The cells are piled up one on the top of the other, the tin plates of the second cell resting on the zinc of the first, and so on. The tin connections—a suggestion of Mr. Varley—are most excellent. Two of these cells are shown in section Fig. 5. The resistance of each of these cells is on an average 0·19 of an Ohm. They are now used at all the telegraph stations where Sir William Thomson's siphon recorder is employed.

In using these batteries in a laboratory where they are not perpetually at work, the best way of managing them may possibly be not to charge them with sulphate of copper except when they are about to be used, and only to put in as much as will do the work required. To calculate the quantity is easy; and any small excess might be worked off through a low resistance. We have been keeping them at work almost night and day. They require no attention except to be occasionally supplied with sulphate of copper crystals, and to have the sulphate of zinc that creeps up over their edges wiped away with a cloth.

At present our battery is tested very frequently, generally once in four or five days. The electromotive force and the internal resistance of each cell is determined. We have now had the greater number of the eighty cells in action for three months, and some of them for five or six months. During all that time they have been most satisfactory, the electromotive force of them having remained perfectly constant.

We test them by means of the reflecting electrometer, or the tangent galvanometer.

J. T. BOTTOMLEY

(To be continued.)

NOTES

AFTER we went to press last week, a most cheering telegram was received in this country respecting the fate of Dr. Livingstone, as follows:—' Aden, May 1, 1872.—The *Abydos* has returned from Zanzibar. She brings news that Dr. Livingstone is safe with Stanley. The news is brought by natives." It may fairly be hoped that still more authentic intelligence will shortly be received respecting the fate of the great traveller, with respect to whom such anxiety has been manifested in this country. Another despatch speaks also of the destruction of a large portion of the town of Zanzibar by a terrible hurricane on April 15.

THE eruption of Vesuvius, respecting which we gave such details as were accessible last week, appears to be over. Whether any scientific results have been obtained by any observers besides Palmieri it is too early yet to know. We hope it may be so, and shall return to the subject as soon as the authentic accounts have been collated.

THE Annual Visitation of the Board of Visitors to Greenwich Observatory will take place on Saturday, June 1st.

THE President, Vice-President, and Council of the Pharmaceutical Society of Great Britain will hold a *conversazione* at the South Kensington Museum on Wednesday evening next, May 15.

AT a meeting of Convocation at Oxford last week, it was carried that in all the schools, except that of theology, examiners might be appointed who were not members of the University. The liberal change which had already been granted for the Natural Science School will do much to widen the general course of reading at that University, and to prevent the studies pursued there partaking too much of any narrow or special character.

MR. CHARLES TOMLINSON, F.R.S., lectures this evening at the London Institution, Finsbury Circus, on Solution and Supersaturation.

AT the Annual Meeting of the Literary and Philosophical Society of Manchester, held on the 30th ult., the following officers were elected for the ensuing year:—President, Mr. E. W. Binney, F.R.S., F.G.S.; Vice-Presidents, Dr. Jas. P. Joule, F.R.S., Dr. E. Schunck, Dr. Robert Angus Smith, F.R.S., and the Rev. W. Gaskell; Secretaries, Prof. H. E. Roscoe, F.R.S., Mr. J. Baxendell. As members of the Council, Mr. Peter Spence, Mr. W. L. Dickenson, Mr. H. Wilde, Mr. R. D. Derbyshire, Prof. Osborne Reynolds, Mr. W. Boyd Dawkins, F.R.S., Prof. Balfour Stewart, F.R.S. Few local societies can boast such a distinguished list of names as the above.

TWO Scholarships of the annual value of 30*l*. and 20*l*. respectively, tenable for two years, have been founded by the Governors of the Middlesex Hospital, for the encouragement of the study of medicine and surgery, in memory of the late Francis Broderip, a munificent benefactor to the hospital. These scholarships will be open to competition, at the end of each winter session, amongst the general students of the hospital who shall have completed their third year of study at the Medical College. The successful candidates will be required to attend and work at the hospital for a fourth year, during which period they will be eligible for the various resident appointments.

TWO Scholarships, of the annual value of 25*l*. and 20*l*. respectively, will be offered for competition at Middlesex Hospital at the commencement of the Winter Session 1872-73. Each scholarship is tenable for two years, provided the scholar conducts himself satisfactorily. These scholarships are open to all gentlemen who commence their medical studies in October 1872. Successful candidates will be required to become general students of the College. The examination will take place on September 27 and following days, and the result will be declared on October 5. The following are the subjects for examination:—Latin, Greek, French or German, Mathematics, Natural Philosophy, Chemistry, Botany, Zoology. Candidates will be examined in any three of the above subjects they may select; but only one Modern Language and two out of the last three subjects are permitted. An equal number of marks will be given to each subject, and candidates will be expected to attain a certain standard of proficiency in the subjects they select. Candidates must send in their names in writing, addressed to the Dean, at the Middlesex Hospital, stating the subjects which they elect for their examination, on or before September 24.

WE referred recently to Tilghman's ingenious process for cutting hard substances by means of a jet of sand. The Committee on Science and the Arts, constituted by the Franklin Institute of the State of Pennsylvania, for the promotion of the mechanic arts, to whom the process was referred for examination, report that they have seen the operation, and that the invention seems capable of extensive use in the arts. Some of the products of the invention appear to present new and valuable features. Glass ornamented by this process can only be compared with that etched by powerful acids, yet the entire absence of all undercutting, no matter how deeply the glass is cut, renders it superior. The great merit of the invention consists in its extended utility. By means of this sand-blast effects have been produced which would be hard to imitate by any other known mechanical process, and with an ease and precision truly remarkable. They consider the invention original and of the highest utility, and deem it worthy of any mark of approbation it may be thought fit to bestow upon its originator. They therefore recommend the bestowal on the inventor of the Elliott Cresson medal of the Franklin Institute, in accordance with the rules governing such award.

PRIZES to the amount of 25*l*. are offered by the proprietors of the *Gardeners' Magazine* for dinner-table decorations in fruit and flowers, or flowers only, arranged for effect in artificial light. The competition is to take place in connection with the Royal Horticultural Society's Exhibition in Birmingham, in June.

PROF. HULL, head of the Geological Survey of Ireland, has in the press a work designed to render practical service to builders and architects by information about the varieties of stone and their respective advantages for building purposes. "In arranging the matter treated in this work," says Prof. Hull, "I have not followed any very definite order, but rather that which the subject seemed to indicate." Regretting the incorrect nomenclature which is employed in the architectural classification of natural building materials, and yet feeling that the adoption of the mineral basis of rocks as the principle of arrangement would render his book less useful for reference by architects, the author has followed the plan drawn out on his fourth page. "Commencing with the noblest of all rocks, granite, I have been naturally led onwards to the allied rocks, such as syenite, porphyry, and from those to other plutonic or volcanic rocks. After these the metamorphic serpentines and marbles form a transition series through the simpler and rarer ornamental stones into those adapted for building, and of aqueous formation." The work will be published by Messrs. Macmillan and Co.

OUR readers will be glad to learn that Dr. Bastian's "Beginnings of Life" will be published shortly after Whitsuntide. This book will be a complete exposition of those views of its author upon vital phenomena, and the conditions of their appearances, which have already excited so much interest and discussion.

THE Rugby Council for Promoting the Education of Women has just published a very useful Calendar of women holding University certificates and engaged in teaching. It contains also all the needful information for those intending to try for the examinations for women and girls conducted by the Universities of Oxford, Cambridge, London, Dublin, Edinburgh, Durham, and the Queen's University for Ireland, and will thus be of essential aid, not only to these, but also to those who are seeking the services of women who have shown themselves capable of obtaining the highest educational honours as yet open to them. It may be obtained of Mrs. F. E. Kitchener, Rugby.

THE Report of the Rugby School Natural History Society for 1871 lies before us. The preface refers with modest pride to several subjects of congratulation by the Society:—nearly all the published papers, some of them of considerable merit, are written by actual members of the school; a meteorological and astronomical section was begun in 1871, in consequence of the establishment of the Temple Observatory, and has been heartily carried out by those members of the school who were competent to serve; a large entomological section is springing up; the members of the Society have doubled during the year; and during the present spring each section has begun fortnightly meetings, from which all but real workers are to be excluded. Every year shows more and more the important place which the Natural History Societies of our public schools are taking in the scientific education of the country.

THE Report of the Marlborough College Natural History Society, now eight years old, for the half-year ending Christmas, 1871, contains no paper bearing directly on the natural history of the district. That good local work is being done by members of the Society is, however, evidenced by the excellent list of entomological notices appended. We cannot unite with the sentence in the Preface that "it is an almost utter impossibility to get any original matter from beginners, and it would be unreasonable to expect any." It ought to be the special aim of school Natural History Societies to cultivate original work rather than mere collecting; the opportunities for it, even for beginners, are endless; and there is no over-estimating the value to the observer of the least morsel of such original work. The papers printed in this Report are excellent in their way; Mr. Babington's on "The Malay Archipelago and its Inhabitants," is a model of what such a paper should be. The Report is illustrated by an admirable plate of *Clavaria fusiformis*, drawn by Mr. F. C. Hulme. We would venture to suggest to the Committee the propriety of excluding in future from a published report personal matters, which, though of great importance to the Society itself, do not interest the outside public.

THE Royal Cornwall Polytechnic Society has published its thirty-ninth Annual Report for 1871. Among the more important lectures and papers contained in it may be mentioned "On the Comparative Health and Longevity of Cornish Miners," containing a large number of very valuable statistics, by Mr. R. Blee; and the "Meteorology of West Cornwall and the Scilly Islands for 1871," by Mr. W. P. Dymond, besides descriptions of a number of mechanical inventions and applications especially valuable to those engaged in mining operations.

THE first excursion of the Geologists' Association to Watford took place on April 13, under the guidance of Messrs. W. Whitaker and J. Hopkinson. The first section visited was a fine one of the Glacial Drift now exposed by the side of the railway near Watford to a depth of 30 feet. The drift is the "Middle Glacial," and consists of sand and sub-angular gravels with pebbles of various rocks, some of which are evidently from very distant localities. After passing through Cassiobury Park, the party proceeded to Bushey Heath, at which place the "Basement Bed" of the London Clay is exposed, with the upper portion of the Woolwich and Reading series. This section was described by Mr. Whitaker, as was also one at Bushey Heath Kiln, where the Woolwich and Reading series is again seen. The formation is, however, represented by beds of sand at the former place, and by pebble beds at the latter. The next excursion was to Hampstead on April 27, directed by Messrs. J. R. Pattison and C. Evans. The party assembled at the Swiss Cottage station, and crossed the fields to Hampstead; but before the village was reached the structure of the hill was described, and the indications of the junction of the London Clay and the Bagshot Sands were observed. The summit of the hill consists of an outlier of the Bagshot Sands overlying the uppermost sandy beds of the London Clay, containing *Pectunculus decussatus* and *Voluta nodosa*. The Conduit spring was visited, and the line of junction of the two formations, indicated by springs and pools, was followed as far as the Vale of Health pond. The highest point of the Heath was then soon gained, and

here the physiography of the district was pointed out. After passing through the West Heath valley, in which a thin bed of water-bearing sand above the clay has produced a swamp, the party visited the residence of Mr. C. Evans, and inspected that gentleman's fine collection of Tertiary fossils.

THE new School of Science and the new Museum and Art Gallery at the rear of the Hartley Hall, Southampton, are fast approaching completion. There are two class rooms of about 20ft. by 16ft. 6in. and 16ft. high, and a large drawing-class room, 32ft. by 16ft. 6in. and 16ft. high. In the Art Gallery and Museum are two large rooms, 42ft. by 20ft., and about 18ft. high, lighted from the roof and connected with the Science School and the Art School.

A FREE Museum has lately been opened at Nottingham in Wheeler-Gate. The greater portion of the objects of interest which are in the museum, now the property of the town, originally belonged to the Nottingham Naturalists' Society, and a considerable number of valuable objects were added from time to time until the museum assumed its present dimensions.

ACCORDING to the Stockholm *Aftonbladet* an important discovery has been made in Sweden. An extensive coal-bed of remarkable depth and excellent quality has been struck near Raus, in Schonen. An enterprising company formed some time ago was encouraged by promising geological indications to institute borings, but the first results were hardly satisfactory. At a depth of 566ft. eleven strata of coal had indeed been pierced, but none of these exceeded in depth 1¼ft. Five feet farther down, however, a bed was struck with a thickness of 8¾ft. The borings have been continued, and are believed to prove satisfactorily the existence of an extensive coal-bed.

A MOST violent cyclone occurred at Madras on May 1. Many vessels were driven on shore, and completely wrecked. The pier has been again breached, and great damage done to the city and suburbs. On Friday, the 3rd, the storm was slightly abating.

AT a recent sitting of the French Academy a letter was read from the French Consular agent at Mostar on the earthquakes felt throughout the Herzegovina during the months of February and March last. The first was felt on the 6th of February, two days after the great aurora borealis. Other oscillations followed on the 7th and 8th, apparently in a N.W. and S.E. direction On the 13th a longer shock was experienced, followed by a loud rumbling sound like distant cannon. On the 25th and 27th stronger shocks, accompanied by noise, were felt, making about forty since the 6th. On March 2 and 3 the manifestations increased in intensity; but neither Ragusa nor Serajevo, so subject to earthquakes, appear to have been at all affected all the time.

SOME time in the summer of 1871 it was stated that Mr. Octave Pavé, a young Louisiana Frenchman, had started toward the North Pole by way of Siberia and Wrangell's Land, and that, in the absence of news from him, the assistance of the Siberian Government had been invoked, in consequence of grave fears for his safety. It now appears that he has not yet started on his mission, but is to sail from San Francisco in May for Kamschatka, where he will take in supplies, and proceed to Cape Yakan, on the north-east coast of Siberia. Here the vessel is to be abandoned, and a further exploration attempted on an India-rubber raft, composed of four rubber cylinders fastened together on the decks by wooden slats, to which the masts and rigging are attached. It is intended to head, after leaving Cape Yakan, for Wrangell's Land, a large island discovered by Captain Long in 1867. This being reached, the island is to be crossed on sledges; and if an open sea occur beyond, he is to take the raft again, and endeavour to sail to Greenland or Spitzbergen. The entire enterprise is conducted at the expense of the traveller; and however hazardous or chimerical the plan may be, we cannot but wish him success in his movements.

*HISTORY OF THE NAMES CAMBRIAN AND SILURIAN IN GEOLOGY**

(*Continued from page* 17)

WHAT then was the value and the significance of the Silurian sections of Murchison, when examined in the light of the results of the Government surveyors? The Llandeilo rocks, having throughout the characteristic *Orthis* so much insisted upon by Murchison, were shown to be the base of a great conformable series, and to the eastward, in Shropshire, to rest on the upturned edges of the Longmynd rocks; while westward, near Bala, they overlie unconformably the Lingula-flags, and in the island of Anglesea repose directly upon the ancient crystalline schists. According to the author of the "Silurian System," there existed beneath the base of the Llandeilo formation a great conformable series of slaty rocks into which this formation passed, and from which it could not be distinguished either zoologically, stratigraphically, or lithologically. The sequence, determined from what were considered typical sections in the valley of the Towey in Caermarthenshire, as given by Murchison, for several years both before and after the publication of his work, was as follows:—1. Cambrian; 2. Llandeilo flags; 3. Caradoc sandstone; 4. Wenlock and Ludlow beds; 5. Old Red sandstone; the order being from north-west to south-east. What then were these fossiliferous Cambrian beds underlying the Llandeilo and indistinguishable from it? Sedgwick, with the aid of the Government surveyors, has answered the question in a manner which is well illustrated in his ideal section across the valley of the Towey. The whole of the Bala or Caradoc group rises in undulations to the north-west, while the Llandeilo flags at its base appear on an anticlinal in the valley, and are succeeded to the south-east by a portion of the Bala. The great mass of this group on the south-east side of the anticlinal is however concealed by the overlapping May Hill sandstone—the base of the unconformable upper series which includes the Wenlock and Ludlow beds. (Philos. Mag. IV. viii. 488) The section to the south-east, commencing from the Llandeilo flags on the anticlinal, was made by Murchison the Silurian system, while the great mass of strata on the north-west side of the Llandeilo (which is the complete representative of the Caradoc or Bala beds, partially concealed on the south-west side) was supposed by him to lie beneath the Llandeilo, and was called Cambrian (the Upper Cambrian of Sedgwick). These rocks, with the Llandeilo at their base, were in fact identical with the Bala group studied by the latter in North Wales, and are now clearly traced through all the intermediate distance. This is admitted by Murchison, who says:—"The first rectification of this erroneous view was made in 1842 by Prof. Ramsay, who observed that instead of being succeeded by lower rocks to the north and west, the Llandeilo flags folded over in those directions, and passed under superior strata, charged with fossils which Mr. Salter recognised as well-known types of the Caradoc or Bala beds." ("Siluria," 4th ed., p. 57, foot-note.)

The true order of succession in South Wales was in fact:—1. Llandeilo; 2. Cambrian (= Caradoc or Bala); 3. Wenlock and Ludlow; 4. Old Red sandstone; the Caradoc or Bala beds being repeated on the two sides of the anticlinal, but in great part concealed on the south-east side by the overlapping May Hill or Upper Llandovery rocks. These latter, as has been shown, form the true base of the upper series which, in the Silurian sections, was represented by the Wenlock and Ludlow. Murchison had, by a strange oversight, completely inverted the order of his lower series, and turned the inferior members upside down. In fact, the Llandeilo flags, instead of being, as he had maintained, superior to the Cambrian (Caradoc or Bala) beds, were really inferior to them, and were only made Silurian by a great mistake. The Caradoc, under different names, was thus made to do duty at two horizons in the Silurian system, both below and above the Llandeilo flags. Nor was this all; for by another error, as we have seen, the Caradoc in the latter position was made to include the Pentamerus beds of the unconformably overlying series. Thus it clearly appears that, with the exception of the relations of the Wenlock and Ludlow beds to each other and to the overlying Old Red sandstone, which were correctly determined, the Silurian system of Murchison was altogether incorrect, and was moreover based upon a series of stratigraphical mistakes, which are scarcely paralleled in the history of geological investigation.

It was thus that the Lower Silurian was imposed on the scientific world; and we may as well ask with Sedgwick, whether

* Reprinted from advance sheets of the *Canadian Naturalist*.

geologists "would have accepted the Lower Silurian classification and nomenclature, had they known that the physical or sectional evidence upon which it was based had been from the first positively misunderstood." Feeling that his own sections were, as has since been fully established, free from error, Sedgwick naturally thought his name of Upper Cambrian should prevail for the great Bala group. Hence the long and embittered discussion that followed, in which Murchison in many respects occupied a position of vantage as against the Cambridge professor, and finally saw his name of Lower Silurian supplant almost entirely that of Upper Cambrian given by Sedgwick, who had first rightly defined and interpreted the geological relations of the group.

In a paper read before the Geological Society in June, 1843 (Proc. Geol. Soc. iv. 212-223), when the perplexity in which the relations of the Upper Cambrian and Silurian rocks were involved had not been cleared up by the discovery of Murchison's errors in stratigraphy, Sedgwick proposed a compromise, according to which the strata from the Bala limestone to the base of the Wenlock were to take the name of Cambro-Silurian; while that of Silurian should be reserved for the Wenlock and Ludlow beds, and for those below the Bala the name of Cambrian should be retained. The Festiniog group (including what were subsequently named the Lingula flags and the Tremadoc slates) would thus be Upper instead of Middle Cambrian, the original Upper Cambrian being henceforth Cambro-Silurian; it being understood that, wherever the dividing line might be drawn, all the groups above it should be called Cambro-Silurian, and all those below it Cambrian. This compromise was rejected by Murchison, who in the map accompanying the first edition of his "Siluria," in 1854, extended the Lower Silurian colour so as to include all but the lowest division of the Cambrian, viz., the Bangor group. When, however, the relations of Upper Cambrian and Silurian were made known by the discoveries of Sedgwick and the Government surveyors, this compromise was seen to be uncalled for, and was withdrawn in 1854 by Sedgwick, who re-claimed the name of Upper Cambrian for his Bala group.

In June 1843, Sedgwick proposed that the whole of the fossiliferous rocks below the horizon of the Wenlock should be designated Protozoic, and on Nov. 29, 1843, presented to the Geological Society an elaborate paper on the Older Palæozoic (Protozoic) Rocks of North Wales, with a coloured geological map. This paper, which embodied the results of the researches of Sedgwick and Salter, was not, however, published at length, but an abstract of it was prepared by Mr. Warburton, then president of the society, with a reduced copy of the map (Proc. Geol. Soc. iv. 212 and 251-268; also Geol. Jour. i. 5-22). In this map of Sedgwick's three divisions were established, viz., the hypozoic crystalline schists of Caernarvonshire, the Protozoic, and the Silurian. On the legend of the reduced map, as published by the Geological Society, these latter names were altered so as to read "Lower Silurian (Protozoic)" and "Upper Silurian." These changes, in conformity with the nomenclature of Murchison, were, it is unnecessary to say, made without the knowledge of Sedgwick, who did not inspect the reduced and altered map until it was appealed to as an evidence that he had abandoned his former ground, and had recognised the equivalency of the whole of his Cambrian with the Lower Silurian of Murchison. The reader will sympathise with the indignation with which Sedgwick declares that his map was "most unwarrantably tampered with," and will, moreover, learn with surprise that an inspection of the proof sheets of Warburton's abstract of Sedgwick's paper was refused him, notwithstanding his repeated solicitations. The story of all this, and finally of the refusal to print in the pages of the *Geological Journal* the reclamations of the venerable and aggrieved author, make altogether a painful chapter, which will be found in the *Philos. Magazine* for 1854 (IV. viii. pp. 301-317, 359-370, and 483-506), and more fully in the "Synopsis of British Palæozoic Rocks," which forms the introduction to McCoy's "British Palæozoic Fossils."

In connection with this history it may be mentioned that in March 1845 Sedgwick presented to the Geological Society a paper on the Comparative Classification of the Fossiliferous Rocks of North Wales and those of Cumberland, Westmoreland, and Lancashire, which appears also in abstract in the same volume of the *Geological Journal* that contains the abstract of the essay and the map just referred to (i. 442). That this abstract also is made by another than the author is evident from such an expression as "the author's opinion seems to be grounded on the following facts," &c. (p. 448), and from the manner in which the terms Lower and Upper Silurian are applied to certain fossiliferous rocks in Cumberland. Yet the words of this abstract are quoted with emphasis in "Siluria" (1st ed, 147), as if they were Sedgwick's own language, recognising Murchison's Silurian nomenclature.

II.—*Middle and Lower Cambrian*

Investigations in continental Europe were, meanwhile, preparing the way for a new chapter in the history of the lower palæozoic rocks. A series of sedimentary beds in Sweden and Norway had long been known to abound in singular petrifications, some of which had been examined by Linnæus, who gave to them the name of *Entomolithi*. They were also studied and described by Wahlenberg and by Brongniart, the latter of whom, from two varieties of the *Entomolithus paradoxus*, Linn, established in 1822 two genera, *Paradoxides* and *Agnostus*. In 1826 appeared a memoir by Dalman on the Palæadæ, or so-called Trilobites; which was followed, in 1828, by his classic work on the same subject ("Ueber die Palæaden oder so-genannten Trilobiten," 4to, with six plates, Leipsic). In these works were described and figured, among many others, two genera—*Olenus*, which included *Paradoxides* Brongn. and *Battus*, including *Agnostus* of the same author. Meanwhile, Hisinger was carefully studying the strata in which these Trilobites were found in Gothland, and in the same year (1828) published in his *Anteckningar*, or Notes on the Physical and Geognostical Structure of Norway and Sweden, a coloured geological map and section of these rocks as they occur in the county of Skaraborg, where three small circumscribed areas of nearly horizontal fossiliferous strata are shown to rest upon a floor of old crystalline rocks, in some parts granitic and in other gneissic in character. The section and map, as given by Hisinger, show the succession in the principal area to be as follows, in ascending order: (1) granite or gneiss, (2) sandstone, (3) alum-slates, (5) orthoceratite-limestones, (4) clay, slates. By a curious oversight the colours on the legend are wrongly arranged and wrongly numbered, as above; for in the map and section it is made clear that the succession is that just given, and that the clay-slates (4) instead of being below, are above the orthoceratite-limestones (5).

In 1837 Hisinger published his great work on the organic remains of Sweden, entitled *Lethæa Suecica* (4to, with forty-two plates). In this he gives a tabular view, in descending order, of the rock-formations, and of the various genera and species described. The rocks of the areas just noticed appear in his fourth or lowest division, under the head of *Formationes Transitionis*, and are divided as follows:—

a. Strata calcarea recentiora Gottlandiæ.
b. Strata schisti argillacei.
c. Strata schisti aluminaris.
d. Strata calcarea antiquiora.
e. Strata saxi arenacei.

The succession thus given was however erroneous, and probably, like the mistake in the legend of the same author's map just mentioned, the result of inadvertence, the true position of the alum-slates (*c*) being between the older limestone (*d*) and the basal sandstone (*e*). This is shown both by Hisinger's map of 1828, and by the testimony of subsequent observers. In Murchison's work on the Geology of Russia in Europe, published in 1845, there is given (p. 15 *et seq.*) an account of his visit to this region in company with Prof. Loven, of Christiania; which, with figures of the sections, is reproduced in the different editions of "Siluria." The hill of Kinnekulle, on Lake Wener, is one of the three areas of transition rocks delineated on the mad of Hisinger above referred to. Resting upon a flat region of nearly vertical gneissic strata, we have according to Murchison, (1) a fucoidal sandstone, (2) alum-slates, (3) red orthoceratite limestone, (4) black graptolitic slates, the whole series being little over 1,000 ft. in thickness, and capped by erupted greenstone. Above these higher slates there are found in some parts of Gothland, other limestones with orthoceratites, trilobites, and corals, the newer limestone strata (*a*) of Hisinger; the whole overlain by thin sandstone beds. These higher limestones and sandstones contain the fauna of the Wenlock and Ludlow of England; while the lower limestones and graptolitic slates afford *Calymene Blumenbachii*, *Orthis calligramma*, and many other species common to the Bala group of North Wales. The alum-slates below these however contained, according to Hisinger, none of the species then known in British rocks, but in their stead five species of *Olenus* and two of *Battus* (*Agnostus*).

In 1854 Angelin published his *Palæontolologica Scandinavica*, part 1, *Crustacea formationis transitionis* (4to, forty-one plates), in which he divided the series of transition rocks above described by Hisinger into eight parts designated by Roman numerals, counting from the base. Of these I. was named *Regio Fucoidarum*, no organic remains other than fucoids being known therein; while the remaining seven were named from their characteristic genera of trilobites, which were as follows, in ascending order; certain letters being also used to designate the parts:—II. (A) Olenus: III. (B) Conocoryphe; IV. (BC) Ceratopyge; V. (C) Asaphus; VI. (D) Trinucleus; VII. (DE) Harpes; VIII. (E) Cryptonymus. In the *Regio Olenorum* (II.) was found also the allied genus *Paradoxides*. With regard to the characteristic genus of Regio III., the name of *Conocoryphe* was proposed for it by Corda in 1847, as synonymous with Zenker's name of *Conocephalus* (*Conocephalites*), already appropriated to a genus of insects.

Meanwhile the similar crustaceans which abound in the transition rocks of Bohemia had been studied and described by Hawle, Corda, and Beyrich, when Barrande began his admirable investigations of this ancient fauna and of its stratigraphical relations. He soon found that beneath the horizon characterised by fossils of the Bala group (Llandeilo and Caradoc) there existed in Bohemia a series of strata distinguished by a remarkable fauna, entirely distinct from anything known in Great Britain, but closely allied to that of the alum-slates of Scandinavia, corresponding to Regiones II. and III. of Angelin. To this he gave the name of the first or primordial fauna, and to the rocks yielding it that of the Primordial Zone. Resting upon the old gneisses of Bohemia appears a series of crystalline schists designated by Barrande as *Etage A*, overlain by a series of sandstones and conglomerates, *Etage B*, upon which repose the fossiliferous argillites of the Primordial Zone or *Etage C*. The rocks of the Etages A and B were by Barrande regarded as azoic, but in 1861, Fritsch of Prague, after a careful search, discovered in certain thin-bedded sandstones of B the traces of filled-up vertical double tubes; which, according to Salter (Mem. Geol. Sur. iii. 243), are probably the marks of annelides, and are identical with those found in the rocks of the Bangor or Longmynd group in Great Britain; which will be shown to belong to the Primordial Zone. It is, therefore, probable that the Etage B, which apparently corresponds to the Regio Fucoidarum or basal sandstone of Scandinavia, should itself be included in the Primordial Zone. It may here be noticed that it is in the crystalline schists of A that Gümbel has found *Eozoön bavaricum*. To the Etage C in Bohemia, Barrande assigns a thickness of about 1,200 feet, and to this his first fauna is confined, while in the succeeding divisions he distinguished a second and a third. The second fauna, which characterises Etage D, corresponds to that of the Bala group; while the third fauna, belonging to the Etages E, F, G, and H, is that of the May Hill, Wenlock, and Ludlow formations of Great Britain.

This classification of the ancient Bohemian faunas was first set forth by Barrande in 1846, in his *Notice Préliminaire*, in which he declared that the first fauna was below the base of the Llandeilo of Murchison, unknown in Great Britain, and, moreover, "new and independent in relation to the two Silurian faunas (his second and third) already established in England." This opinion he reiterated in 1859. These three divisions form in Bohemia an apparently continuous series, and being connected with each other by some common species, Barrande was led to look upon the whole as forming a single stratigraphical system; and finally to assert that these three independent faunas "form by their union an indivisible triad which is the Silurian system." (Bul. Soc. Geol. de Fr. II. xvi. 529-545.) Already, in 1852, in his magnificent work on the Silurian System of Bohemia, Barrande had given to the strata characterised by his first fauna the name of Primordial Silurian. It is difficult to assign any just reason for thus annexing to the Silurian—already augmented by the whole Upper Cambrian or Bala group of Sedgwick, (Llandeilo and Caradoc)—a great series of fossiliferous rocks lying below the base of the Llandeilo, and unsuspected by the author of the Silurian system; who persistently claimed the Llandeilo beds, with their characteristic second fauna, as marking the dawn of organic life.

Up to this time the primordial palæozoic fauna of Bohemia and of Scandinavia was, as we have said, unknown in Great Britain. The few organic remains mentioned by Sedgwick in 1835 as occurring in the region occupied by his Lower and Middle Cambrian, on Snowdon, were found to belong to Bala beds, which there rest upon the older rocks; nor was it until 1845 that Mr. Davis found in the Middle Cambrian remains of *Lingula*. In 1846, Sedgwick, in company with Mr. Davis, re-examined these rocks, and in December of the same year described the Lingula beds as overlaid by the Tremadoc slates and occupying a well-defined horizon in Caernarvon and Merionethshire, beneath the great mass of the Upper Cambrian rocks. (Geol. Jour. ii. 75, iii. 139.) Sedgwick, at the same time, noticed about this horizon certain Graptolites and an *Asaphus*, which were supposed to belong to the Tremadoc slates, but have since been declared by Salter to pertain to the Arenig or Lower Llandeilo beds, the base of the Upper Cambrian. (Mem. Geol. Sur. iii. 257, and Decade II.)

This discovery of the Lingula flags, as they were then named, and the fixing by Sedgwick of their geological horizon, was at once followed by a careful examination of them by the Government surveyors; and in 1847, Selwyn detected in the Lingula flags, near Dolgelly, in Merionethshire, the remains of two crustacean forms, the one a phyllopod, which has received the name of *Hymenocaris vermicauda* Salter, and the other a trilobite, which was described by Salter in 1849 as *Olenus micrurus*. (Geol. Survey, Decade II.) A species of *Paradoxides*, apparently identical with *P. Forchammeri* of Sweden, was also about this time recognised among specimens supposed to be from the same horizon. It has since been described as *P. Hicksii*, and found to belong to the basal beds of the Lingula flags—the Menevian group.

Upon the flanks of the Malvern Hills there are found resting upon the ancient crystalline rocks of the region, and overlain by the Pentamerus beds of the May Hill sandstone (originally called Caradoc by Murchison) a series of fossiliferous beds. These consist in their lowest part of about 600 feet of greenish sandstone, which have since yielded an *Obolella* and *Serpulites*, and are overlain by 500 feet of black schists. In these, in 1842, Prof. John Phillips found the remains of trilobites, which he subsequently described, in 1848, as three species of *Olenus* (Mem. Geol. Survey ii. part 1, 55). These black shales, which had not at that time furnished any organic remains, were by Murchison in his "Silurian System" (p. 416) in 1839 compared to the supposed passage beds in Caermarthenshire between the Llandeilo and the Cambrian (Bala) rocks; which, as we have seen, were newer and not older strata than the Llandeilo flags. From their lithological characters, and their relations to the Pentamerus beds, these lower fossiliferous strata of Malvern were subsequently referred by the Government geologists to the horizon of the Caradoc proper or Bala group; nor was it until 1851 that their true geological age and significance were made known. In that year, Barrande, fresh from the study of the older rocks of the Continent, came to England for the purpose of comparing the British fossils with those of the Primordial Zone which he had established in Bohemia and Scandinavia, and which he at once recognised in the Lingula flags of Sedgwick and in the black schists at Malvern; both of which were characterised by the presence of the genus *Olenus*, and were referred to the horizon of his Etage C. This important conclusion was announced by Salter to the British Association at Belfast in 1852 (Rep. Brit. Assoc., abstracts, p. 56, and Bull. Soc. Geol. de Fr. II. xvi. 537). Since that time the progress of investigation in the Middle and Lower Cambrian rocks of Wales has shown a fauna the importance and richness of which has increased from year to year.

The palæontological studies of Salter, while they confirmed the primordial character of the whole of the great mass of strata which make up the Middle Cambrian or Festiniog group of Sedgwick (consisting of the Lingula flags and the Tremadoc slates), led him to propose several sub-divisions. Thus he distinguished on palæontological grounds between the upper and lower Tremadoc slates, and for like reasons divided the Lingula flags into a lower and an upper portion. For the discussion of these distinctions the reader is referred to the memoirs of the Geol. Survey (iii. 240-257). Subsequent researches led to the division of the original Lingula flags into three parts, an upper and a middle, to which the names of Dolgelly and Maentwrog were given by Mr. Belt, and a third consisting of the basal beds, which were separated in 1865 by Salter and Hicks, with the designation of Menevian, derived from the ancient Roman name of St. David's in Pembrokeshire. It was here that in 1862, Salter found *Paradoxides* with *Agnostus* and *Lingula* in fine black shales at the base of the Lingula flags, resting conformably on the green and purple grits of the Lower Cambrian or Harlech beds. The locality was afterwards carefully studied by Hicks,

and it was soon made apparent that the genus *Paradoxides*, both here and in North Wales, was confined to a horizon below the great mass of the Lingula flags, which, on the contrary, are characterised by numerous species of *Olenus*. These lower or Menevian beds are hence regarded by Salter as equivalent to the lowest portion of the Etage C of Barrande.

Beneath these Menevian beds there lies, in apparent conformity, the great Lower Cambrian series, frequently called the bottom or basement rocks by the Government surveyors; represented in North Wales by the Harlech grits, and in South Wales, near St. David's, by a similar series of green and purple sandstones, considered by Murchison and by others as the equivalent of the Harlech rocks. They were still supposed to be unfossiliferous until, in June 1867, Salter and Hicks announced the discovery in the red beds of this lower series, at St. David's, of a *Lingulella*, very like *L. ferruginea* of the Menevian (Geol. Jour. xxiii. 339; Siluria, 4th ed. 550). This led to a further examination of these Lower Cambrian beds, which has resulted in the discovery in them of a fauna distinctly primordial in type, and linked by the presence of several identical fossils to the Menevian; but in many respects distinct, and marking a lower fossiliferous horizon than anything known in Bohemia or in Scandinavia.

The first announcement of these important results was made to the British Association at Norwich in 1868. Further details were, however, laid before the Geological Society in May 1871 by Messrs. Harkness and Hicks, whose paper on the Ancient Rocks of St. David's Promontory appears in the Geological Journal for November 1871 (xxviii. 384). The Cambrian sediments here rest upon an older series of crystalline stratified rocks, described by the geological surveyors as syenite and greenstone, and having a north-west strike. Lying unconformably upon these, and with a north-east strike, we have the following series, in ascending order:—1, quartzose conglomerate, 60ft.; 2, greenish flaggy sandstone, 460ft.; 3, red flags or slaty beds, 50ft., containing *Lingulella ferruginea*, besides a larger species, *Discina*, and *Leperditia cambrensis*; 4, purple and greenish sandstones, 1,000ft.; 5, yellowish gray sandstones, flags and shales, 150ft., with *Plutonia*, *Conocoryphe*, *Microdiscus*, *Agnostus*, *Theca*, and *Protospongia*; 6, gray, purple and red flaggy sandstones, with most of the above genera, 1,500ft.; 7, gray flaggy beds, 150ft., with *Paradoxides*; 8, true Menevian beds, richly fossiliferous, 500ft. The latter are the probable equivalent of the base of Barrande's Etage C, and at St. David's are conformably overlain by the Lingula flags, beneath which we have, including the Menevian, a conformable series of 3,370ft. of uncrystalline sediments, fossiliferous nearly to the base, and holding a well-marked fauna distinct from anything hitherto known in Great Britain or elsewhere.

The Menevian beds are connected with the underlying strata by the presence of *Lingulella ferruginea*, *Discina pileolus*, and *Obolella sagittatus*, which extend through the whole series; and also by the genus *Paradoxides*, four species of which occur in the lower strata, from which the genus *Olenus*, which characterises the Lingula flags, seems to be absent. To a large tuberculated trilobite of a new genus found in these lowest rocks the name of *Plutonia Sedgwickii* has been given. Hicks has proposed to unite the Menevian with the Harlech beds, and to make the summit of the former the dividing line between the Lower and Middle Cambrian, a suggestion which has been adopted by Lyell. (Proc. Brit. Assoc. for 1868, p. 68, and Lyell, Student's Manual of Geology, 466—469.)

Both Phillips and Lyell give the name of Upper Cambrian to the Lingula flags and the Tremadoc slates, which together constitute the Middle Cambrian of Sedgwick, and concede the title of Lower Silurian to the Bala group or Upper Cambrian of Sedgwick. The same view is adopted by Linnarsson in Sweden, who places the line between Cambrian and Silurian at the base of the Llandeilo or the second fauna. It was by following these authorities that I, inadvertently, in my address to the American Association for the Advancement of Science in August 1871, gave this horizon as the original division between Cambrian and Silurian. The reader of the first part of this paper will see with how much justice Sedgwick claims for the Cambrian the whole of the fossiliferous rocks of Wales beneath the base of the May Hill sandstone, including both the first and the second fauna. I cannot but agree with the late Henry Darwin Rogers, who, in 1856, reserved the designation of "the true European Silurian" for the rocks *above* this horizon. (Keith Johnston's Physical Atlas, 2nd ed.)

T. STERRY HUNT

(*To be continued*)

*ACOUSTICAL EXPERIMENTS**

SHOWING THAT THE TRANSLATION OF A VIBRATING BODY CAUSES IT TO GIVE A WAVE-LENGTH DIFFERING FROM THAT PRODUCED BY THE SAME VIBRATING BODY WHEN STATIONARY

The Apparatus

FOUR tuning-forks mounted on resonant cases and giving the note UT^3, = 256 complete vibrations per second, were obtained. I will designate them as Nos. 1, 2, 3, and 4.

Nos. 1 and 2 were brought into perfect unison by a process to be described.

No. 1 was placed before a lantern, and just touching one of its prongs was a small ball (5 or 6^{mm} diam.) of good cork, suspended by a silk fibre. The images of the fork and of the cork ball were projected on a screen.

No. 3 had one prong weighted with wax, so that it gave two beats a second with No. 1 or 2.

No. 4 had the ends of its prongs filed off, until it also gave two beats per second with 1 or 2; thus No. 4 gave two vibrations a second more than No. 1, while fork No. 3 gave two vibrations a second less than No. 1.

The Experiments

In the experiments one to seven inclusive, fork No. 1 remains before the lantern, with the suspended cork ball just touching one of its prongs.

EXP. 1. Fork No. 2, screwed on its case, was held in the hand, at a distance of 30 to 60 ft. from No. 1, and sounded; the ball was projected from the prong of fork 1, which vibrated in unison with 2.

EXP. 2. I stationed myself 30 ft. distant from fork No. 1, and fork No. 2 was screwed off its case and vibrated in one hand, while the case was held in the other. I now walked rapidly toward fork 1, and after I was in regular motion I placed the fork on its case, and just before I ceased walking I took it off; although, when I did so, I was only about a foot from fork 1, yet the cork ball remained at rest against its prong.

EXP. 3. Again I walked toward 1, as in Exp. 2, but I did not remove the fork from its case after it was placed on it. The ball remained at rest until the moment I suddenly stopped walking; at that instant the ball flew from the fork, while an assistant, whose ear was close to the case of fork 1, while his eye was directed to the screen, found that at the instant I stopped walking, the fork 1 sounded, while the ball jumped from its prong.

EXPS. 4 and 5. These experiments were exactly like Exps. 2 and 3, except that I walked away from fork 1 instead of approaching it. The results were the same as in Exps. 2 and 3.

EXP. 6. Fork No. 3, giving 254 vibrations per second, was sounded as in Exp. 1. It had no effect in moving the ball. I now screwed the fork off its case, and, standing about 30 ft. from fork 1, with my arm I swung the case toward fork 1, and while it was approaching it I placed fork No. 3 on the case; the proper velocity (from eight to nine feet per second) having been obtained, the ball was suddenly projected from fork 1. On greatly increasing or decreasing the above velocity of the moving case, the vibrations of fork 3 produced no effect on fork 1.

EXP. 7. Fork No. 4, which gives two vibrations per second more than No. 1, was substituted in Exp. 6, but was placed on its swinging case when this was receding from fork 1. The effect of this motion and of varying velocities was the same as in Exp. 6.

EXP. 8. I placed fork 3 before the lantern, and swung fork 1 as in Exp. 7. The effects were the same as described in Exp. 7.

EXP. 9. I now placed fork 4 before the lantern, and moved fork 1 as in Exp. 6. The effect on the ball was the same as in Exp. 6.

By these simple experiments I have shown the change of wave-length produced by the translation of the vibrating body, and have given an experimental proof of the important theorem which Doppler established in 1841. By analogy they clearly unfold that exquisite modern method of determining the motions

* By Alfred M. Mayer, Ph.D., Professor of Physics in the Stevens Institute of Technology, Hoboken, New Jersey (reprinted from the *American Journal of Science and Arts*, vol. iii., April, 1872).

of a heavenly body by variations in the refrangibility of the rays which it emits—motions often impossible even to detect by any other means. I therefore deem it proper that I should proceed to state the delicate conditions on which depend the perfection of experiments which so satisfactorily elucidate the nature of those grand and refined problems offered to spectral observation.

It is, first of all, essential that forks 1 and 2 should really be in unison. Two forks, sounded together, may give no perceptible beats, for they may constrain each other into a common forced oscillation, and thus both will give the same number of vibrations, yet may be removed from equality when separately vibrated. The process I have adopted is as follows: Three forks are taken which are supposed to give the same number of vibrations in a given time. They are supported on india-rubber tubing, and are thus insulated One of the forks is now loaded so that it gives two or three beats in a second, with one of the other two that are to be brought into exact unison. The interval of time occupied by twenty or thirty of these beats is accurately determined by means of a chronograph (one of Casella's registering stop-watches does very well). The interval occupied by the same number of beats given with the second fork is now ascertained, and if it differs from that given by the first, the quicker vibrating fork is made to give the same number of beats as the slower by loading it with wax. When the forks have thus been carefully adjusted, I have had no difficulty in projecting the ball, in Exp. 1, at a distance of sixty feet, and I believe that it could have been accomplished at a distance of 100 feet. The ball of cork should be *spherical*, so that it will always just touch the fork, no matter how much it may rotate around its suspending thread, which latter should consist of only one or two fibres of unspun silk. The cork is rendered as smooth as possible and is then *varnished*; this is important, for the varnish gives a firm coating to the ball, without sensibly increasing its weight, and is especially useful in covering the minute asperities or elastic projections on its surface, which otherwise would act as "buffers" to the impacts of the fork and deaden its projectile effects.

The above-stated conditions having been obtained, no physicist will have any difficulty in repeating these experiments.

A machine has been devised by which a uniform motion of translation can be given to the forks, and with this I propose making a quantitative investigation of the phenomena, using an apparatus essentially the same in its action as the one here described.

We may substitute for the suspended cork-ball a light plane mirror, held between two stretched vertical fibres, while one of its edges touches the fork. The motions of a beam of light reflected from the mirror to a screen, indicate most beautifully the vibrations of the fork. This ingenious and most delicate device for detecting vibrations is due to Prof. O. N. Rood, of Columbia College, N.Y., who first used it in a public lecture, delivered in New York on the 28th of last December. We have, however, in our special work, found the image of the projected ball more convenient, and sufficiently delicate, for our experiments.

Quantitative relations in the experiments and analogical facts in the phenomena of light.

The UT_3, No. 1 fork, makes 256 complete vibrations in one second, while fork No. 3 makes 254, giving for the respective wave-lengths of these vibrations 4·367 and 4·401 feet, which we will designate in order as λ and λ'. We will take 1,118 feet per second as the velocity of sound at 60° F.

Now 256 vibrations in 1,118 ft. make $\lambda = 4{\cdot}367$ ft.
and 254 „ „ $1{,}118 - 2\lambda\,(=1{,}109{\cdot}266)$ give $\lambda = 4{,}367$ ft.

As the velocity of propagation of the vibrations and λ are the same in both cases, it follows that $\left(n = \frac{V}{\lambda}\right)$, the number of vibrations in a second, reaching a distant point, is the same, and, therefore, 256 vibrations from a body at rest will produce the same effect on a distant surface, as 254 vibrations emanating from a body which moves toward that surface, with a velocity of 2λ, or of 8·734 feet per second; and this is the velocity we gave the fork in Exps. 6 to 9.

We will now examine the analogical phenomena in the case of light. Let fork No. 1, giving 256 vibrations a second, stand for 595 millions of millions vibrations a second, which we will take as the number of vibrations made by the ray D_1 of the spectrum. Then fork No. 3 will represent 590 millions of millions vibrations per second, which gave a wave-length ·0000042 millimetre longer than that of D_1, and nearly corresponds with an iron line situate ·42 div. below D_1 on Angström's chart. We saw that fork No. 3, giving 254 vibrations a second, had to move toward the ear with a velocity of 8·734 ft, to give the note produced by 256 vibrations per second, emanating from a fixed point; so a star sending forth the ray which vibrates 590 millions of millions times a second, will have to move toward the eye with a velocity of 28,470 miles per second to give the colour produced when ray D_1 emanates from a stationary flame.

SCIENTIFIC SERIALS

Annalen der Chemie und Pharmacie, October 1871. Naumann has made a long series of experiments on the dissociation-tensions of ammonic carbonate; he finds that when it is volatilised it is entirely decomposed into ammonia and carbonic anhydride, and that for lower temperatures the dissociation-tensions of this body increase by increase of temperature precisely as the tensions of other substances. Leist has obtained three compounds of bismuth oxide with sulphuric acid, all of which are basic salts, he has not been able to form the normal salt except in combination with potassium. Faust has made a series of experiments on the derivatives of phthalic acid, he has obtained nitrophthalic, bromophthalic, and dechlorophthalic acids. Faust and Saame have made a careful examination of the chloro-compounds, both addition and substitution of naphthaline: this work has already been performed many years ago by Laurent; the authors have thought fit to commence a revision of the subject, but it is as yet far from complete. A very long paper by Schutzenberger follows "on the acetyl derivations of carbo-hydrates, mannite and its isomerides, and on certain vegetable products," this contains some interesting though complicated results. A translation of Dr. Mills' paper on the nitration of chloroform, and two other papers of less interest complete this number.

Annales de Chimie et de Physique, March 1872.—The greater portion of this number is occupied by the second part of MM. Pierre and Puchot's researches on some of the bodies produced in fermentation. They give the results of a very detailed study of propylic alcohol, its haloid ethers, the formiate, acetate, propionate, butyrate, and valerate, and propylic aldehyde; butylic alcohol and the same series of ethers as above, and amylic alcohol with its butyrate and valerate. Besides these we have the detailed description of several other ethers, methyl valerate, and ethyl propionate and valerate, forming altogether a very complete and exhaustive monograph on these subjects. The author has also made some interesting observations on the "simultaneous distillation of water with certain alcohols insoluble therein." Thus a mixture of water and amylic alcohol, when submitted to distillation, boils at 96°, and a definite proportion of the two bodies is found in the distillate, at this temperature 2 parts of water and 3 of amylic alcohol invariably condense; should the water be in excess the whole of the amylic alcohol will pass over, the thermometer remaining at 96°. Butylic alcohol and water distil over at 90·5° when a constant mixture of 5 parts of alcohol and 1 part of water condenses.—M. Bourgoin has electrolysed a solution of potassic phthalate, and finds that it splits up into water, carbonic oxide, and carbonic anhydride, an aqueous solution of phthalic acid does not appear to be decomposed by the electric current.

THE *Scottish Naturalist* for April contains a number of short articles on various branches of Scottish Natural History. Among the more interesting may be mentioned especially a note by Dr. Buchanan White on the discovery in Braemar of a colony of *Zygæna exulans*, a common moth in the Alpine districts of Southern Europe and in Scandinavia, but hitherto unknown in Britain. Dr. White considers it, like some of the characteristic plants of the district, a relic of the glacial epoch which once overspread Scotland; its characters are intermediate between the northern and southern forms.—Mr. George Sim contributes an important paper, comprising a list of the stalk-eyed Crustacea of the north-east coast of Scotland, with descriptions of new genera and species, and a plate.—The instalment of the catalogues of Insecta Scotica includes a continuation of the Lepidoptera by Dr. Buchanan White, and the commencement of the Coleoptera by Dr. D. Sharp.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 2.—"On some Elementary Principles in Animal Mechanics.—No. V. On the most perfect form of a Plane Quadrilateral Muscle connecting two Bones.—No. VI. Theory of Skew Muscles, and investigation of the conditions necessary for Maximum Work." By Rev. Prof. Haughton, F.R.S.

"On the Rings produced by Crystals when submitted to Circularly Polarised Light." By William Spottiswoode, Treas. R.S.

Geological Society, April 24.—Prof. Ramsay, F.R.S. V.P. in the chair. 1. "An Extract from a Despatch from H.M. Minister in Teheran." This letter described the effects of some severe earthquake shocks experienced at Khabooshan in North-Western Khorassan. On December 23, 1871, an earthquake occurred which destroyed half the town of Khabooshan, and buried about 2,000 of its inhabitants in the ruins. On January 6, 1872, another severe shock destroyed the remainder of the town, and killed about 4,000 people. Four forts near the town were so completely buried that not a trace of them can be seen. It was estimated that 30,000 lives were lost in Khabooshan, Bojnoord, and the surrounding villages by the effects of these earthquakes. 2. "Notes on the Geology of the Colony of Queensland," by R. Daintree. The author stated that Alluvial deposits are very scanty in Queensland, except on the northern shores of Carpentaria and near the mouths of the larger rivers. The fossil remains of extinct Mammalia (*Diprotodon*, *Macropus*, *Thylacoleo*, *Nototherium*, &c.) are found in old brecciated alluvia, representing beds of old watercourses, through which modern creeks have cut their channels. With these mammalia are found shells of existing species. Of Cainozoic deposits the most important is called the "Desert Sandstone" by the author; it consists of horizontal beds of coarse grit and conglomerate, nowhere exceeding 400 feet in thickness, forming a sandy barren soil by their disintegration. The only fossils found in it are rolled fragments of coniferous wood; and its stratigraphical position is determined solely by its resting unconformably upon beds containing apparently Cretaceous fossils. The author considered that this deposit formerly covered nearly the whole of Australia. Beds containing Mesozoic forms of fossils, and referred by the author to the Cretaceous series, occur upon the Upper Flinders. At Marathon these deposits consist of a fine-grained yellow sandstone, and below this a series of sandstones and argillaceous limestones, containing four species of *Inoceramus*, with a species of *Ichthyosaurus* and two of *Plesiosaurus*. At Hughenden station, near Mount Walker, there is a series of calcareo-argillaceous beds, probably inferior to those of Marathon, and containing two species of Ammonites, with *Avicula gryphæoides*, a *Pecten*, &c. At Hughenden Cattle Station, twenty miles farther up the river, numerous Belemnites are found loose upon the surface. The Mesozoic rocks also extend down the Thompson River and its tributaries. The author referred to the fossils described by Mr. Charles Moore as probably Oolitic, and stated that it is more than probable that Oolitic and Cretaceous rocks extend throughout the whole of Central Queensland, and thence to Western Australia. On the eastern side of the dividing range a small patch of ferruginous grit containing *Panopæa plicata* occurs near Pelican Creek; and from Gordon Downs species of *Panopæa*, *Pholadomya*, and *Cucullæa* have been obtained. These beds probably represent a lower horizon than those on the Flinders River; and a large portion of the colony east of the dividing range is covered by freshwater deposits, containing plant-remains (including *Tæniopteris*), and in their upper part a fauna apparently intermediate between the Gordon Downs and Flinders River series. In these deposits, on the Cnodamine, Brisbane, and Mary rivers, numerous Coal-seams exist. The author supposes that, contemporaneously with the deposition of a series of marine beds to the west of the dividing range, during the Oolitic and part of the Cretaceous period, a vast lacustrine deposit was accumulated over a large area to the eastward of the range, to which the sea subsequently obtained access. Among the Palæozoic deposits, the author distinguished Carboniferous and Devonian rocks. The *Carboniferous* series was said to be represented in Northern Queensland by an extensive Coal-field. The upper portion of the series (grits, sandstones, and shales) contains chiefly fossil plants, the most abundant being a *Glossopteris*. The lower strata (generally *argillaceous* limestone) contain *Producti*, *Spiriferæ*, &c. of true Carboniferous type, intermixed with scanty and imperfect remains of the above-mentioned plants. A set of fossils from the head of the Don River were said to agree with those found in the Hunter River series of New South Wales. *Devonian* rocks extend from 18° S. lat. to the southern boundary of Queensland and for 200 miles inland. They consist of slates, sandstones, and Coral-limestones. The upper portion of this series contains an abundance of fossil plants, the deposits containing which, at Mount Wyatt, are interstratified with beds containing *Spiriferæ*, and other fossils of Devonian type occur in beds reached by shafts sunk through these strata. In the limestone of the lower portion of the series corals are very numerous. On the Broken River this formation may be best studied. Gold is found in many parts of the Devonian district, and the author entered in considerable detail into its mode of occurrence there. Metamorphic rocks were described by the author as occurring in various localities. At the Cloncurry, Cape River, Gilbert, Peak Downs, Black Snake, Kilkwan, and Goaroomjain Diggings there are mica- and hornblende-schists, whilst at the Ravenswood Diggings the rock is a granite with triclinic felspar. The latter, which contains more or less hornblende, the author regarded as of metamorphic origin. The author noticed the connection between the presence of certain trappean rocks in these metamorphic areas and in the Devonian area, and the production of auriferous and cupriferous lodes. True *Granites* crop out along the eastern coast of Queensland, and these vary much, passing into porphyry and quartz-porphyry, but monoclinic felspar always predominates in them. The intrusive Trappean rocks, which are regarded as influencing the production of auriferous vein-stones in the Devonian and Metamorphic rocks, are noticed at considerable length by the author, and consist of pyritous porphyrites and porphyries, pyritous diorites and diabases, chrome-iron serpentines and pyritous felsites; the author considers that this order probably indicates the succession of these rocks in time. The veinstones he thinks were probably deposits of mineral matter from the hydrothermal action which preceded, accompanied, and continued long after the cooling of the traps themselves. The volcanic rocks, in the author's opinion, have played a most important part in determining the elevation and present physical outline of North-eastern Queensland; they follow the line of greatest elevation on the main watershed at altitudes of from 1,500 to 2,000 feet above the sea-level. The general arrangement of the other rocks referred to is epitomised by the author as follows:—"With the exception of the McKinlay ranges, a line drawn parallel with the eastern coast at a distance of 250 miles would include all the Palæozoic, Metamorphic, Granitic, Trappean, and Volcanic rocks represented in the colony, both coal-groups lying within the same area. The Mesozoic and Cainozoic systems occupy the surface area to the westward. The descent going eastward is first locally a thin capping of 'Desert Sandstone,' next Carboniferous, then Devonian, and possibly Silurian, with patches of metamorphic and granitic rocks interspersed. The chief granitic mass extends from Broad Sound to Cape York, with an occasional capping of 'Desert Sandstone.'" The paper contained numerous analyses of the various rocks, and the fossils have been worked out by Messrs. Etheridge and Carruthers, whose lists and descriptions of them are appended to the paper.

Linnean Society, May 2.—Mr. G. Bentham, president, in the chair.—Dr. Joseph Leidy, of Philadelphia, and Prof. Notaris, of Genoa, were elected to the two vacant places in the list of foreign members.—On *Alibertia edulis*, by Senor Correa de Mello.—Mr. Miers exhibited a substance which he had received from the Brazilian Government, which it was thought might, to a certain extent, become a substitute for cotton. It is a product of the liber of a climbing plant of unknown relationship, and can be procured in any quantity, furnishing a fibre of very strong and silky texture.

Anthropological Institute, May 6.—Sir John Lubbock, Bart., president, in the chair. The following papers were read:—"Note on the Peculiarities of the Australian Cranium," by Mr. S. M. Bradley, F.R.C.S.; "Notes on a Scaphoid Skull," by Dr. Barnard Davis, F.R.S.; "On Certain Points concerning the Origin and Relations of the Basque Race," by Rev. W. Webster and Mr. Stuart Menteath; "Mann: its names and their origins," by Mr. J. M. Jeffcott; "Vocabulary of Original Dialects of Queensland," by Mrs. Barlow; "On the Mode of Preparing the Dead among the Natives of the Upper Mary River, Queensland," by Mr. A. McDonald.

DUBLIN

Natural History Society, February 7.—Prof. E. Perceval Wright, M.D., in the chair.—The following gentlemen were

elected as officers and council of the society for the present session:—President—Prof. E. Perceval Wright, M.D.; Vice-Presidents—Mr. William Archer, Dr. Alexander Carte, Dr. Robert M'Donnell, Lord Ventry; Honorary Treasurer—Mr. A. Andrews; Honorary Secretaries—Mr. William Andrews and Dr. A. W. Foot; Council—Mr. R. Ball, Mr. H. Barton, Rev. S. Haughton, M.D., M. A. Jacob, M.D., Mr. T. Kift, Mr. A. Macalister, M.B., Mr. D. Moore, Mr. M. Barrington, Mr. Edward Crowe, Dr. Fraser, Rev. T. O'Mahony, M.A., Rev. Eugene O'Meara, M.A., and Mr. George Porte. Dr. E. P. Wright returned thanks to the members for the honour they had conferred upon him, and stated that, at the suggestion of the Hon. Secretary, he would defer the introductory address to the next meeting of the Society.

Kilkenny

Royal Historical and Archæological Association of Ireland, April 3.—Rev. P. Moore in the chair.—The secretary exhibited an ancient ecclesiastical seal of the Primatial See of Armagh, and read a report on the state of the Round Tower of Kilmacduagh, County Galway. The following papers were read: "On the old Church of Donaghmore, County Limerick, with a photograph," by the Rev. M. Malone; "On the old Kilkenny Canal," by A. Walters; "On the Corrack or Ancient Wicker Boat covered with Skin," by W. F. Wakeman; "On an Ancient Bell found near the old Church of Drumrath, County Tyrone, with a photograph, and on a Silver Ring-brooch found in the Crannog of Aghalougher, County Antrim," by J. Nolan.

Vienna

Imperial Academy of Sciences, March 21. — Prof. Hlasiwetz presented a memoir by M. A. Exner, on the synthesis of hyponitric acid, N^2O^4. — Prof. Suess made a preliminary communication on the structure of the Italian Peninsula, in which he showed that the mountain chain which forms the Calabrian peninsula is a fragment of the tectonic axis of the peninsula, but that the continuation of this axis lies concealed under the Tyrrhenian sea. The southern half of the western part of the Alps is also sunk beneath the plain of Lombardy. The Appenines form the north-eastern, and Sicily a fragment of the south-western, subsidiary zone of the Tyrrhenian mountain chain; and the volcanoes stand for the most part either in series on the margins of fracture, or in groups in the middle of the regions of depression. The relation of the Hungarian trachytes to the Carpathians is the same as that of the Italian volcanoes to the Appenines.—Prof. E. Weiss reported upon the difference of longitude between the observatory of Vienna and that at the Military Academy of Wiener-Neustadt.—Dr. H. W. Reichardt reported upon the Botanical Results of the Polar Expedition of 1871. The number of species brought by Lieutenant Payer was about thirty; they were collected in the southern part of Spitzbergen and some adjacent islands, and in Hope Island.

EXAMINATIONS IN TECHNOLOGY

NO subject has been more talked about of late years than Technical Education. No term has been more vaguely or indefinitely used than this, even in education, that region of loose definition; yet it cannot be doubted that at the present time no subject is of more vital importance to this country, to enable it to maintain its manufacturing position, than a general diffusion of sound technical knowledge—a knowledge, that is, which rests on a thorough apprehension of the scientific principles which lie at the root of the various arts and manufacturing processes.

Bacon, in the first of his "General Aphorisms for Interpreting Nature and Extending the Empire of Man over Creation," says:—"Man, who is the servant and interpreter of Nature, can act and understand no further than he has, either in operation or in contemplation, observed of the method and order of Nature." And he proceeds, "neither the hand without instruments, nor the unassisted understanding, can do much; they both require helps, the understanding no less than the hand, to fit them for business. . . . . The knowledge and power of man are coincident; for whilst ignorant of causes he can produce no effects, nor is Nature to be conquered but by submission. And that which in speculation stands for the cause, is what in practice stands for the rule." The men of science of our day are not open to Bacon's rebuke to the mathematician, the physician, and the chemist of his day, that they were concerned in the works of Nature, but all of them superficially and to little purpose. Day by day sees them conquering Nature by submission. Are the thousands engaged in our manufacturing industries capable of taking advantage of their conquests? How painfully true with respect to them still are his words, written some 250 years ago, "The works hitherto discovered are owing rather to accident and trial than to the sciences."

Playfair remarks on this, "One of the considerations which appear to have impressed Bacon's mind most forcibly was the vagueness and uncertainty of all the physical speculations existing in his time, and the entire want of connection between the Sciences and the Arts." The vagueness and uncertainty of physical speculation is rapidly clearing away. Is the connection between the Sciences and the Arts as rapidly being cemented? We fear not. The world has become imbued with the truth of Bacon's saying, that "in works men can do no more than put natural bodies together and take them asunder; all the rest is performed by the internal operations of Nature." But how little is the order of Nature which should regulate this putting together and taking asunder understood in our workshops! How much is trusted to trial and error! How little is the store of knowledge accumulated by our men of science drawn upon! How great is the waste of our resources!

We therefore hail with satisfaction a scheme of technological examinations proposed by Captain Donnelly, R.E., which the Society of Arts has adopted on the recommendation of an able committee of scientific and professional men to whom it was referred, and which it appears, from a paper lately issued, the Society intends to carry out if the requisite support be forthcoming.

The proposal of Captain Donnelly is briefly that every year the Society of Arts should arrange for the examination in the science and technology of certain arts and manufactures. A committee qualified to advise on the subject is to prepare a syllabus of the examination in each branch of industry. It is an instruction to them "that it is essential that the candidate should possess, on the one hand, such an elementary knowledge, at least of science, as will prove that he understands the scientific principles of which his art is an application; and, on the other hand, such a knowledge of the application of those principles in his trade, as will show that he is practically conversant with the various processes and manipulations of the factory or workshop. The theoretical knowledge must not be a mere 'cram' of empirical dicta, nor the practical knowledge a mere committal to memory of descriptions of manufactures picked up from text-books." This instruction shows that the technology which it is proposed to cultivate by means of these examinations is thoroughly sound.

The requirements from a candidate fall naturally under three heads. We have first those branches of abstract science which are involved in the special industry under consideration; secondly, the special applications of those abstract or general sciences to that industry; and lastly, a practical knowledge of the machinery, processes, and manipulation.

The examinations of the Science and Art Department, which are now held pretty generally in all parts of the kingdom, and which can be extended to any place which desires to avail itself of them, by the simple process of forming a local committee of superintendence, provide the ready means of testing the candidates' knowledge of any branches of general science. It is only necessary then to determine what branches of science are the foundation of the technology of any industry, and to specify the examination which the candidate shall pass for each grade of certificate. The Society of Arts, working in concert with the Science and Art Department, proposes to avail itself therefore of these examinations to determine the candidate's knowledge of pure science.

As respects the technology or special applications of general science, the committee will prepare a syllabus for each industry. And the examination in these matters will also be conducted by means of the local committees after the general science examinations, the papers of questions being prepared by special examiners, to whom the answers will be submitted. Finally, the candidate's practical knowledge will be ascertained by a return of his employment in the factory or workshop, giving his rate of wages, &c., certified by his employer, somewhat in the form of the return required from candidates for Whitworth Scholarships. No more reliable criterion of a candidate's practical knowledge could be afforded than this. It is in the workshop, and in the workshop alone, that a true practical education can be obtained. It is a great advantage that this scheme wholly avoids running counter to the just susceptibilities of our manufacturers on this cardinal doctrine, and pro-

poses simply to strengthen and ennoble this practical education by combining it with sound scientific instruction. The whole machinery of the examination is simple, effective, and, by means of local co-operation—a machinery which already exists—readily applicable, at small cost, to all parts of the kingdom.

The examinations are to be adapted to three grades of certificates: an elementary, or "Workman's" certificate; an advanced, or "Foreman's" certificate; and an honours, or "Manager's" certificate.

No syllabus has yet been issued, but we have seen the syllabus for paper manufacture, which, though not finally adopted by the committee, is in a forward state. How many candidates will come up to the mark? We fear but few. There is no use shutting our eyes to the fact. Among manufacturers how many are there who could pass a fair examination in the Science and Technology of their trade? And yet the committee have not pitched their standard too high. One great benefit—if no other—will be conferred by these committees. They will show at least what ought to be known.

As a commencement, Captain Donnelly proposes that those industries should be taken for examination which form the subjects of the Annual International Exhibitions, and that the Royal Commissioners for the Exhibition of 1851 should be asked to provide the requisite funds. The committee endorse Captain Donnelly's view, and think that the Council of the Society of Arts "may find it advantageous to include those Arts and Manufactures." We trust that it may be found practicable to include annually many more, and that this important movement will not be left to depend on the Annual Exhibitions alone, however ready the Commissioners may be to support it. It is for the manufacturers of this ountry, for the City Companies, and the large towns, whose very existence depends on their manufacturing supremacy, to come forward and aid this important work, and do for their several industries what Sir Joseph Whitworth has done for mechanical engineering by his noble endowment.

By this means a stimulus will be given to the extension of scientific instruction; an aim and organisation afforded of which it stands in much need; and a decided step taken to re-establish our manufacturing supremacy, which, in consequence of the superior educational position of our continental rivals, is now trembling in the balance.

WATTS'S DICTIONARY OF CHEMISTRY

A Dictionary of Chemistry. By Henry Watts, F.R.S., B.A., &c. *Supplement.* (Longmans, Green, and Co., London, 1872.)

ENGLISH chemists will hail with gladness the appearance of the supplemental volume to "Watts's Dictionary." It was evident almost before the completion of the last volume of the original work, that a supplementary volume would be required very shortly. In these days of progress chemical books are quickly left behind, and it needs energetic measures for our literature to keep pace with fresh chemical discoveries. Chemistry has much to be thankful for at the hands of Mr. Watts. The present volume brings up our knowledge to the end of 1869, and also includes several additions, corrections, &c., which have appeared in 1870 and 1871. The scope of this volume is, as in former volumes, sufficiently wide; the contents are not entirely confined to chemistry, but include articles on electricity, heat, light, &c. The connection between these subjects and chemistry is so close that no book would be perfect which did not enter into and explain some of the effects caused by these forces. The plan of "Watts's Dictionary" is too well known to require any comment. The present volume is strictly a continuation of the former ones; and, as time rolls on, other supplemental volumes will be required to make this record of chemical history complete. As it is, we now possess in "Watts's Dictionary" a complete account of chemical discovery up to the end of 1869; and in the abstracts of foreign papers published by the Chemical Society we have a contemporaneous record of all new facts, beginning, however, with the year 1871. It is, perhaps, unfortunate either that Mr. Watts did not bring out his Supplement one year later, or that the Chemical Society did not commence their extremely valuable work one year earlier. At the present time, therefore, we have one year to a certain extent unrepresented. We have, however, gained a great step; instead of having to wait two or three years for the appearance of the "Jahresbericht," we have now the abstracts of foreign papers a month or so after their publication. It is worthy of remark that Mr. Watts's dictionary has outstripped the "Jahresbericht," the third volume of which, for 1869, has not yet appeared. The author has fortunately succeeded in obtaining the assistance of some of the former contributors to his work, thus Prof. C. G. Foster contributes two very clear articles on recent discoveries in electricity and heat, whilst Prof. Roscoe has written the articles on "Light and on Spectrum Analysis," which give a very excellent *résumé* of the work done in these branches of science, and which, perhaps, might have been lengthened with advantage. The article on "Proteids" is written by Prof. M. Foster, whose name is a sufficient guarantee for its excellence. Dr. Paul and Mr. Wanklyn have also contributed to the Supplement, the latter having written on acetic ether (in part), on butyl alcohols, &c. The only possible objection to this outside help is that, in some instances, undue prominence may be given to certain of the author's theories or remarks, to the comparative overlooking or slighting of the work of other chemists. We must not, however, omit to speak in the highest terms of many of the articles contributed by Mr. Watts himself, such as the extremely clear and succinct account of the aromatic series as explained by Kékulé's hypothesis, the article "On Atomicity," and many others too numerous to mention. We cannot give the volume greater praise than by saying it is quite equal to the former productions of the author. Since the publication of the last volume, the chemistry of the aromatic series seems to have usurped the principal attention of chemists, as we find by long articles on benzine, on its derivatives and homologues, no less than forty-five pages being thus occupied; then again the substitution derivatives of benzoic acid and of phenol occupy a considerable space. Another subject which seems to have attracted a considerable amount of attention, and to have yielded very interesting results, is that of the alcohol

cyanides and nitriles. An article on inorganic analysis, by Bunsen's flame reactions, will be found of great interest, and will repay a considerable study. In fact, the whole volume is most complete, and must be looked on with great satisfaction. A. P.

OUR BOOK SHELF

Index der Petrographie und Stratigraphie der Schweiz und ihrer Umgebungen. Von B. Studer, Professor der Geologie. Pp. 272. (Bern: K. Schmid. London: Williams and Norgate)

TWENTY years having elapsed since the publication of the "Geologie der Schweiz," Prof. Studer thinks that some new account of the geology of his country cannot be deemed superfluous. Since the date of that work numerous separate volumes, papers, maps, &c., relating to the geology of Switzerland have appeared. Many of these, however, are difficult of access, and not a few have been to all intents and purposes lost sight of. As a consequence of this, it is exceedingly difficult or even impossible for the student of Swiss geology to find out what has been written. This is easily understood when we remember that Switzerland has been a favourite field of study with geologists of all nations, and that descriptions of her rock-masses and formations are to be met with in the publications of almost every scientific society in Europe. Prof. Studer complains, and not without reason, that many of the names of rock-divisions and formations are derived from little obscure outlying places, for which we look in vain on the best maps, or from fossils which are familiar to only a few adepts, and that the same rock or formation, as the case may be, is known by different names in different regions, thus giving rise in the student's mind to confusion worse confounded. This index (the preparation of which must have cost its author a world of labour) will smooth the way to learners, and will, we are persuaded, be of scarcely less value to professors themselves. Petrological and stratigraphical synonyms are clearly explained, and the equivalents of the Swiss rocks met with in adjoining countries are given. The index is arranged alphabetically, and the list of "articles" leaves nothing to be desired. The descriptions are short, clear, concise, and at the same time comprehensive, those which relate specially to Swiss geology being of course the fullest. The author modestly says that his index makes no pretensions to be a text-book, and refers his readers for greater details to the works of Naumann, Zirkel, Senft, Cotta, &c.; yet we think that the very absence of minute details will be one of its chief recommendations to the geologist, who can always turn to the text-books and other sources when he feels inclined, for the index literally bristles with references. A long list of localities is added, by consulting which we are referred to the various articles in which they are mentioned. Thus, with a good map and Prof. Studer's index before him, one may gather a very clear conception of Swiss geology. The book is not bulky, and will be an invaluable companion to any geologist who thinks of trying his hammer in the "playground of Europe." J. G.

On the Early Stages of an Ascidian (Cynthia pyriformis). By Edward S. Morse, Ph.D. (Boston: 1871.)

IN this communication, reprinted from the Proceedings of the Boston Society of Natural History, Dr. Morse gives an account of his examination of the tadpole-like larva of a sessile Tunicate at Eastport, Maine, in July 1870. He confirms the statements of Kowalewsky and Kupffer, and describes "a remarkable structure in the caudal fin, which vividly recalled the fine diverging rays seen in the embryo fish. These rays were exceedingly delicate, though plainly marked. They ran off nearly parallel to the longitudinal axis of the tail, and were confined to the last five segments." This observation, if confirmed, will be of importance; it points rather to general piscine affinities in the Tunicata than to their special connection with *Amphioxus.* We are glad to see that Dr. Morse is alive to the danger of mistaking the effects of preserving fluids for natural appearances in microscopic specimens. Some neat figures illustrate the paper, which we hope is only the beginning of more complete investigation of this deeply interesting subject by the writer.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Magnetism in Copper Slags

ON examining the magnetic properties of some ores and minerals, I observed that a specimen of ore furnace slag from copper smelting was strongly polar magnetic.

Being surprised at this phenomenon, I mentioned it to Dr. Percy, Professor of Metallurgy at the Royal School of Mines, who kindly gave me permission to examine some of his slags, and also some of those exhibited in the Geological Museum.

I examined several specimens of ore furnace slags, and found they were all more or less magnetic and strongly polar; this even extended to some very small pieces the size of a pea. Most of these were of the ordinary kind, and of a porphyritic appearance, from the pieces of white quartz imbedded in their mass.

One specimen was of a vitreous character. This was not so strongly magnetic as the ordinary kind.

Metal slags from the second fusion.—Those examined were polar magnetic. They were Museum specimens, beautifully crystallised; the magnetic properties were distinct throughout the mass, though more feeble than in the ore slags.

Roaster slags from the third fusion.—I examined two specimens of this class; both were polar magnetic, but the magnetism was confined to a few points, and was not developed in the whole mass, resembling the consequent points in magnetism.

Refinery slags.—I examined one specimen; it was very feebly magnetic, though not polar, and the magnetism was confined to a few points in the mass.

In the analysis of copper slags, the iron present is always estimated as protoxide in combination with silica, forming a silicate of protoxide of iron. Unless this silicate is magnetic, it is difficult to understand how the whole of the iron is thus combined. Further analysis must decide this point.

EDMUND F. MONDY

The Volcanoes of Central France

GEOLOGISTS state that the volcanoes of Auvergne have not been in action in historic times (see Lyell, last ed., p. 479; also Jukes and Geikie, p. 354). I find, however, that the Rogation Days were appointed by Mamercus, Bishop of Vienne, in Gaul, about A.D. 460, for the purpose of chanting litanies to stay the volcanic eruptions which were then devastating his diocese (see Robertson's "Hist. Ch. Church," 4th ed., vol. i. p. 589; also "Proctor on Book of Common Prayer," note, page 251.)

The Eruption of Vesuvius in 1855

IT has occurred to me that, at the present moment, the subjoined extract from the travelling notes of my husband, the late Dr. Marshall Hall, might be thought worthy of insertion in your valuable periodical. We happened to be at Naples when the eruption of Vesuvius in May 1855 occurred, of which the following gives some description:—

"During five years Vesuvius had remained in a state of inactivity, when, on May 1, 1855, indications of an eruption manifested themselves.

"Early on the morning of the 1st smoke and fire appeared,

occupying a point on the north-west side of the mountain, and red-hot lava began to flow down the Atrio del Cavallo.

"On May 2 we all left our hotel at a quarter-past 5 P.M. for Vesuvius, driving up to the Hermiage, and then walking about a mile to the incandescent stream.

"The distant view presented a zig-zag line of fire. As we approached we saw the movement of this stream of lava; in some points solid masses were turned over and moved downwards; in others, bright points occurred where some tree or other combustible was inflamed. Nothing could be more splendid. It was a river of fire from fifty to one hundred yards in breadth.

"We had seen the Falls of Niagara and the glaciers of the Alps, all of a stupendous beauty; but this was sublime and fearful.

"The lava on which we stood, near this stream was warm and on raising a portion the substratum was red-hot. Was it quite safe to be there?

"The view was magnificent, and our position possessed quite sufficient of the fearful to make it sublime: a scene of moving molten masses of liquid fire.

"The stream issued, not from the summit of the mountain, as heretofore, but from its north-western side, on which seven apertures existed. From the highest of these a burst of fire took place upwards from time to time.

"The stream seems to issue in a viscid half-liquid state, whilst its surface, and especially its edges, cold by contact with the atmosphere, become solid, forming a channel and floating or rolling masses. The lava remains long incandescent, even when it has become solid, being a bad conductor of heat. On the same principle the masses of consolidated lava are formed in minor masses, giving to the general mass of surface the most irregular forms, frequently with sharp and prominent edges and projections. Even when these masses are the smallest, it is difficult and even dangerous to walk upon them.

"On Saturday, May 5, I ascended to the summit with Dr. Bishop and my son. From the great crater at the summit there issued much smoke, consisting chiefly of sulphurous acid gas. This proved extremely irritating to the nostrils and bronchia, inducing sneezing and coughing. Three openings existed near together along the edge of the crater at the very summit, which emitted a similar vapour. At points considerably lower, three larger openings were formed on the north side of the cone, from which immense quantities of smoke issued, mingled with fire, differing somewhat in colour, and depositing sulphur of a light green, orange, and bright yellow colour. At a distance the green sulphur, spread over ancient lava, was mistaken, even by our guide, for vegetation, but proved to be sulphur on a nearer examination.

"Below the third of these larger openings there was a cascade of red-hot lava from the edge of a precipice, of immense dimensions, presenting a sublime fall of liquid fire.

"Along this part of the cone masses of stone continually rolled down the slope, dislodged by the movement of the cone (for none were ejected), which some of our party felt distinctly.

"Below the fall the lava proceeded in a continuous stream, consisting partly of flowing, partly of rolling masses, pursuing an irregular course downwards in the Atrio del Cavallo, in one place dividing into two, in others taking a zig-zag turn. From its surface a dense smoke arose generally, but in some places the existence and combustion of a tree gave a bright blaze of light.

"The surface of some parts of the lava stream had already cooled and consolidated sufficiently to admit of our walking over it. This surface was crisp and wave-like, and in some parts sounded hollow when struck with our staffs.

"We picked up one specimen of porous lava, in a crevice of which a fly of considerable size was imprisoned, a miniature picture of Herculaneum or Pompeii. Our boots were torn to tatters." CHARLOTTE HALL

Brighton, May 10

Earthquakes and Permanent Magnets

IN a notice by Dr. A. B. Meyer in No. 116, vol. v. of NATURE, respecting earthquakes in the Island of Celebes, he states that the often-repeated story of the keepers of permanent magnets detaching themselves, and falling at the moment of an earthquake shock, was never verified in his experience. If I remember rightly, this peculiar action was first mentioned by a Frenchman living on the west coast of South America, and much doubted by many at the time. It is not likely that there is any difference between the effect of an American and an Asiatic earthquake on the magnet, if any such exists; but I must state, in corroboration of Dr. Meyer's note, that I have had a permanent magnet and keeper suspended in my study for many years, expressly for the purpose of testing this matter, and on no occasion of an earthquake has the keeper fallen from the magnet, not even in the terrific earthquake of 1863, which was so destructive to the city of Manila and the neighbouring provinces.

The terrestrial disturbances still continue in the Philippines, and almost every post brings us intelligence of earthquakes in the provinces. More has occurred lately: an eruption of the Mayou, a magnificient volcano in the province of Albay, unaccompanied, however, by any serious disasters. As I have already mentioned in my notice of the new volcano which suddenly broke out in the island of Camiguin,* the past year has been remarkable for the great number of earthquakes throughout the Archipelago, especially in the great island of Mindanao, where the new military colony on the great river suffered greatly.

Manila W. W. WOOD

The Australian Eclipse Expedition

IN your number of NATURE for December 7, 1871, it is stated, in regard to the Eclipse Expedition, that "notwithstanding the supineness displayed by the other Australian colonies, it was still hoped that the Government of Victoria would render such pecuniary assistance as would make it possible for the Expedition to set out with some chance of success in obtaining results of scientific value."

Now, while giving all honour to the Royal Society of Victoria for originating and carrying out the expedition, it is only bare justice to the colonies of New South Wales and Queensland to state that, but for the liberal way in which they responded to the cause of science, there would have been no Eclipse Expedition here. No steamer could be obtained in Victoria within the means of the Royal Society, and, at the instance of the Government of New South Wales, who were moved by their astronomer, the Government of Queensland lent a steamer and contributed 115*l*. in money; while the Government of New South Wales contributed 330*l*. to the funds of the Royal Society of Victoria for the Eclipse Expedition, and upwards of 130*l*. towards the expense of steamer and their own observing party, besides sending Lieut. Gowlland, without whose aid in navigating the ship in those dangerous waters, the ship would not have been lent, and there would have been no Expedition here.

A SYDNEY MEMBER OF THE ECLIPSE EXPEDITION

Sydney, March 25

*** Our information was derived from correspondents in Australia. We gladly notify the correction, and give the Governments of Queensland and New South Wales their due.—ED. NATURE.

Waterspouts in the Fen-land

THE letter of Mr. Gray on a waterspout observed by him on the river Ebwy, which appeared in your number for April 25, vividly recalled a similar case which has come under my notice in the Fen-land.

During the summer of 1870, while in Deeping Fen on a day when the wind was blowing in gusts, carrying the dry powdery peat-dust in clouds before it, I observed a whirling column of dust advancing towards me. It was like those smaller pillars so frequently seen in the streets of a town on such a day, but was considerably larger, being from 15 to 20 feet in height. When it was first seen it was advancing from the far side of a *ground*, as the unenclosed fields are called, towards me at the rate of about six miles an hour, and was distant some five hundred yards. It moved with an unsteady staggering motion, accompanied with a rushing noise. I stayed to watch it cross a dyke about 15 feet wide, which ran directly across its path. The smaller dykes it seemed to cross without affecting them, but on reaching the one in question it whisked the water up into a waterspout some 10 feet high with a gurgling hissing sound, and steering directly across the dyke burst on reaching the opposite shore, projecting a considerable quantity of water upon the land. This effort seemed to spend its force, for the dust-column resumed on the opposite

* In some accounts of this phenomenon, the island of Camiguin on the coast of Mindanao, has been confounded with another island of the same name in the Bataanes, to the north of Luzon.

land was but small in proportion, and after swaying about for a few yards, died away.

I have been informed of similar cases in this district, but the above is the only instance in which I observed a waterspout myself. SYDNEY B. J. SKERTCHLY

H.M. Geological Survey, Wisbech, May 2.

The Geologists' Association at Watford

IN the notice in your last number of the excursion of the Geologists' Association to Watford there is a slight error which perhaps I may be permitted to correct.

The sections of the Woolwich and Reading Series which were examined are at Watford Heath Kiln and at Bushey Kiln (*not* Bushey Heath), and the formation, although varying very much in the short distance (scarcely a mile) that these places are apart, is at each place represented by beds of clay, sand, and pebbles. The pebble beds are, however, better seen at the latter than at the former place. JOHN HOPKINSON

Temperature of Hill and Valley

IN NATURE of May 2, page 19, there is an interesting report of a paper by Mr. Dines "On the Temperature of Hill and Valley," showing that (to use Mr. Gaster's words in the discussion) "the air is colder on the top of the hill than in the valley, by day, when the sun is shining, and warmer at night when it is not shining." This appears anomalous at first sight, but I believe it has long been known, and it is easily explained. The temperature of the hill top is not produced where it is observed. As Mr. Glaisher stated in the same discussion, the higher we go in a balloon the less is the range of temperature; and the temperature at the top of a hill which is at all isolated, or even steep on one side, approximates to that observed in a balloon at the same absolute height.

The reason why temperature has a less range in the higher atmospheric strata, is that the earth has very much more power of both absorbing and radiating heat than the molecules of air, and consequently heats more rapidly in the daytime and cools more rapidly at night. The temperature of air at the surface of the earth is determined much more by the absorption and radiation of the earth than by its own.

The truth of this view is shown by the fact that the law is quite different for table-lands from that which we have seen to be true for isolated hills. On table-lands the diurnal range of temperature is greater than on low plains, though on isolated hills it is less. These facts appear to show that while, other conditions being given, the mean temperature of a station chiefly depends on its height above the sea level (or, in other words, the thickness of the atmosphere above it) the diurnal range at the station (whether hill top or balloon) chiefly depends on the proximity of the atmospheric stratum surrounding it to the surface of the earth.

The fact stated in the same paper that "in cold weather the air on the top of the hill is never so cold as that in the valley," is no doubt partly due to the cause above stated, but partly also, I think, to the fact that cold air is heavier than warm, and seeks the lowest position. I believe there is no doubt this is the explanation of the *glacières* or freezing caverns of the Jura described in the Rev. Harold Browne's book.

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Co. Antrim, May 8

Meteors

I OBSERVED a meteor at about half-past eleven on the night of the 8th inst., in the constellation Scorpio, which passed very close to the star Antares, travelling from right to left.

It appears to me worth remarking from the fact of its course lying very near, and roughly parallel to, that part of the ecliptic which corresponded to the earth's position in her orbit.

It traversed some eight or ten degrees of arc, and was visible for three or four seconds, gradually increasing in brightness till it was nearly on a par with Antares, which star it also resembled in colour. Its slow apparent motion immediately suggested the idea that it was moving in the same plane and direction as the earth; in fact, that it was overtaking us in an orbit just outside our own.

The course of another meteor, seen about half an hour earlier from a westerly window, and described to me as not very inferior to Jupiter, appears also to have lain in the direction of the ecliptic, but from left to right, in the neighbourhood of the constellations Gemini, Cancer, or Leo.

It is rash to generalise from such insufficient data, but I conceive these meteors may both have belonged to a system whose orbit lies nearly in the plane of the earth's; the apparent retrograde motion of the last-named being caused by the direction of its path crossing our orbit at a point behind the earth's then place instead of in advance of it.

Cardiff, May 10 GEO. C. THOMPSON

The Ivory Crayfish

I THINK it may be interesting to some of the readers of NATURE to know that a specimen of the "Ivory crayfish," or *Astacus (Cambarus) pellucidus*, mentioned in the very interesting communication of Dr. Packard on the Mammoth Cave of Kentucky in NATURE, April 18, has been living in the aquarium-house in the Regent's Park for a considerable time. The specimen was brought over at the close of the last year by Mr. Boyd from the Mammoth Cave; it is now placed in the first fresh-water tank on the right hand of the visitor as he enters the aquarium. Its dark-loving habits do not permit it to be seen much, as it generally burrows partially under a large stone, from beneath which only the tips of its white claws can be seen.

Culverlea, Winchester, May 8 W. A. FORBES

THE AMERICAN ACADEMY OF SCIENCES

THE Annual Meeting of the National Academy of Sciences was convened, on the 16th of April last, at the Smithsonian Institution in Washington. The existence of this body was authorised by an Act of Congress passed in 1863; and it was originally limited to fifty members, designed to represent the most eminent men of science in the country, who were to be organised for the purpose of serving as advisers to the United States Government in questions of a scientific nature. The Academy has rendered excellent service in this capacity, and has had referred to it very many important questions, the satisfactory solutions of which have saved much money to the Government, and increased the efficiency of many of its bureaus. One condition of membership is that all such service to the Government is to be performed without charge.

As this Society, by its national character, takes the lead of State Institutions for a similar object, and the number of members was at first limited, considerable dissatisfaction was felt by many persons who believed themselves worthy of membership, but were excluded by this restriction. The Academy, therefore, after mature deliberation, decided to ask Congress to remove the limitation as to number, which being done, the principal business of the Academy at its late meeting consisted in the increase of its force. Twenty-five new members were selected, representing the various branches of theoretical and applied science, and the number is to be increased by five each succeeding year. Very few papers or communications were presented to the Academy, as all the time of the meeting was required in carrying out the changes involved by the alteration of the charter, including the formation of a new constitution and rules for its government.

The following is the list of members elected:—Prof. C. A. Young, Dartmouth; Prof. E. D. Cope, Philadelphia; Prof. J. Lawrence Smith, Louisville; W. S. Sullivant, Columbus; Prof. W. B. Rogers, Boston; J. H. Trumbull Hartford; Prof. J. P. Cooke, Cambridge; Dr. A. S Packard, jun., Salem; Prof. W. P. Trowbridge, New Haven; J. E. Oliver, Massachusetts; Prof. E. W. Hilgard, Oxford, Maine; Prof. R. Pumpelly, State Geologist, Missouri; Prof. J. H. Lane, Coast Survey; Prof. A. E. Verrill, New Haven; Dr. J. W. Crafts; Theodore Lyman, Boston; Prof. A. M. Mayer, Stevens Institute, Hoboken; Prof. H. J. Clarke, Amherst; J. Ericsson; Prof. Hadley, New Haven; Dr. F. A. Genth, Philadelphia; Charles A. Schott, Coast Survey; Prof. A. H. Worthen, State Geologist, Illinois; Captain J. B. Eads, St. Louis; General H. L. Abbott, U.S.A.

NATURAL SCIENCE SCHOLARSHIPS AT OXFORD

FOR WHICH ELECTIONS WILL BE MADE DURING THE YEAR 1872

BALLIOL COLLEGE.—One Scholarship, value 70*l.* per annum, and tenable for three years, is generally given. There are two such Natural Science Scholarships on the foundation of Miss Brakenbury, and a third is usually added by the College. Papers are set in Physics, Chemistry, and Biology; the Examination in Chemistry and Biology will be partly practical if necessary. Candidates, if Members of the University, must not have exceeded eight Terms from their Matriculation. The Examination takes place in November.

CHRIST CHURCH.—Not less than one Studentship, of the annual value of 75*l.*, together with rooms rent free, and tenable for five years from the day of Election. The subjects of Examination are Physics, Chemistry, and Biology; but no Candidate is expected to offer himself for examination in more than two of the three. Candidates must not have exceeded the age of twenty on the 1st of January preceding the election. The Examination is held in the middle of February.

JESUS COLLEGE.—One open Scholarship, value 80*l.* per annum, is occasionally given. It is tenable to the close of the twentieth Term from the Scholar's Matriculation. Papers are set in Chemistry, Physics, and Biology; but answers are not expected in more than two subjects. Candidates will have to satisfy the Electors of their ability to pass the ordinary Classical Examinations required by the University. Candidates must not on the day of Election be full twenty-four years old. The Examination takes place in October, and full notice is given early in June. Two Scholarships have been given.

MAGDALEN COLLEGE.—One or more Demyships, value 95*l.* per annum, inclusive of all allowances, and tenable for five years, provided that the holder does not accept any appointment which will, in the judgment of the Electors, interfere with the completion of his University Studies. No person will be eligible who shall have attained the age of twenty years. In conducting the Examination, Questions will be put relating to General Physics, to Chemistry, and to Biology, including Human and Comparative Anatomy and Physiology, with the principles of the classification and distribution of Plants and Animals; but a clear and exact knowledge of the principles of any one of the above-mentioned Sciences will be preferred to a more general and less accurate acquaintance with more than one. The Examination in Biology and Chemistry will be partly practical, if necessary. Candidates have also to satisfy the Electors of their ability to pass the ordinary Classical Examinations required by the University, and for this purpose will have:—*a.* To translate a passage of English Prose into Latin. *b.* To bring up for Examination one Greek author, or a portion, such as five books of Homer, or two Greek Plays, or any equivalent; one Latin author, or a portion, such as the Georgics, or five books of the Æneid of Virgil, or three books of the Odes and the De Arte Poetica of Horace, or any other equivalent. *c.* To answer Questions in Greek and Latin Grammar. Very superior excellence, however, in Natural Science will be allowed to compensate for any deficiency which Candates may have shown in the Classical part of the Examination. Candidates will be required to bring with them a Certificate of Birth, with testimonials of good conduct and character, extending over a period of at least three years, from the Head Master of their School, or from the Private Tutor with whom they may have been reading. The Demyships are open without any restriction as to place of Birth or Education to all Candidates, whether already Members of the University or not, who are found to satisfy the above-named conditions. The Examination will be held in common with Merton College, at the same time and with the same Papers. Each Candidate will be considered as standing, in the first instance, at the College at which he has put down his name, and, unless he has then given notice to the contrary, will be regarded as standing at the other College also. The Examination usually commences on the first Tuesday in October. No Entrance Fees or Caution Money are required by the College. The University Fees payable on Matriculation amount to 2*l.* 10*s.*

MERTON COLLEGE.—One Postmastership, value 80*l.* per annum, tenable for five years, or so long as the holder does not accept any appointment incompatible with the full pursuance of the University studies. Papers will be set in Chemistry, Physics, and Biology; and an opportunity will be given of showing a knowledge of practical work in Chemistry and Biology. The Postmastership will be given for special excellence in one subject, or for excellence in two of the three subjects; but no Candidate will be examined in more than two subjects. There is no limit of age for the Candidates, but a limit of six Terms of University standing. The Examination will be held in common with Magdalen College at the same time, and with the same Papers. Each Candidate will be considered as standing, in the first instance, at the College at which he has put down his name, and, unless he has given notice to the contrary, will be regarded as standing at the other College also.

NEW COLLEGE.—Candidates for Exhibitions may offer to be examined in Natural Science, in addition to the Classical Examination, or in lieu thereof. There is no restriction of age, but no Candidate must have already entered on residence in another College or Hall. The Examination usually takes place in March.

UNIVERSITY SCHOLARSHIP.—*Burdett-Coutts Scholarship.*—One Scholar is elected every year in Lent Term. Candidates must have passed all the Examinations necessary for the Degree of B.A., and not have exceeded the twenty-seventh Term from their Matriculation. The Examination is in Geology, and in Chemistry and Biology as bearing on Geology.—*Radcliffe's Travelling Fellowship.*—One Fellowship, value 200*l.* per annum, and tenable for three years, is filled up each year in Lent Term. For conditions of Examination and Election, see "The Oxford University Calendar."

A LECTURE ON THOMSON'S GALVANOMETER

DELIVERED TO A SINGLE PUPIL IN AN ALCOVE WITH DRAWN CURTAINS

THE lamp-light falls on blackened walls,
And streams through narrow perforations;
The long beam trails o'er pasteboard scales,
With slow-decaying oscillations.
Flow, current! flow! set the quick light-spot flying!
Flow, current! answer, light-spot! flashing, quivering, dying.

O look! how queer! how thin and clear,
And thinner, clearer, sharper growing,
This gliding fire, with central wire
The fine degrees distinctly showing.
Swing, magnet! swing! advancing and receding;
Swing, magnet! answer, dearest, what's your final reading?

O love! you fail to read the scale
Correct to tenths of a division;
To mirror heaven those eyes were given,
And not for methods of precision.
Break, contact! break! set the free light-spot flying!
Break, contact! rest thee, magnet! swinging, creeping, dying.

$\frac{dp}{dt}$

*ON MEASURING TEMPERATURES BY ELECTRICITY**

THE truth revealed to us by one of the younger branches of physical science, which has been cultivated and expounded nowhere more effectually than within these walls, has divested heat and electricity of their mysterious character, and has taught us to regard them simply as "modes of motion."

Light also has been shown to be identical in its nature with heat, and the only remaining physical agency, "chemical affinity," has been recognised as a force differing only in "quality of action" from the others. According to these views, force, in whichever type of action it presents itself, is as indestructible as matter itself, and is therefore capable of being stored up and measured with the same certainty of result. We have a unit of force, or the foot lb., and a unit of heat, or the heat necessary to raise the temperature of 1 lb. of water through 1° Fah., and it has been already proved that 772 units of force are the equivalent value of one unit of heat. Again, the chemical force residing in 1 lb. of pure coal is equal to about 14,000 heat units, or $14,000 \times 772 = 10,808,000$ ft. lbs. = 4,825 tons lifted one foot high.

Questions regarding the quantitative effects of heat present themselves, however, much less frequently for our consideration than questions regarding its intensity, upon which depends the nature of the phenomena surrounding us at every step, both in science and in ordinary life. The instrument at our command for determining moderate intensities or temperatures, the mercury thermometer, leaves little to be desired for ordinary use; but when we ascend in the scale of intensity, we soon approach a point when mercury boils, and from that point upward we are left without a reliable guide. The result is that we find in scientific books on chemical processes statements to the effect that such or such reaction takes place at a dull red heat, such another at a bright red, a cherry red, a blood red, or a white heat—expressions which remind one rather of the days of alchemy than of chemical science of the present day.

There are pyrometers, it is true, but these are either of a complex nature, or little reliance can be placed on them.

It is my purpose this evening to place before you an instrument by which I hope to fill up to some extent the existing gap. It is the result of occasional experimental research, spread over several years, and it aims at the accomplishment of a double purpose, that of measuring high temperatures, and of measuring with accuracy the temperatures of inaccessible or distant places.

But before entering upon the details of my subject, I propose to place before you an instrument which fulfils, in principle, all the conditions essentially necessary in thermometry, and is at the same time the very first instrument that was ever proposed for measuring temperatures. I speak of the air thermometer by Galileo. It can be shown on theoretical grounds that the expansion of a permanent gas at constant pressure is the most perfect index of temperature. It is, in fact, the degree of energy of the atomical motion in an elastic fluid which determines its volume, and which constitutes at the same time its temperature.

The air thermometer consists simply of a bulb of glass with a long tubular stem, open to the atmosphere at its extremity. If I heat the bulb (by dipping it, for instance, into boiling water) and put it into a holder, with the hollow stem reaching downward into a cup of mercury, the air within the bulb will no longer communicate directly with the atmosphere, because the mercury is interposed. If now I cool the air within the bulb, by the external application of iced water, its heat motion will diminish, and its volume would be reduced proportionally, if the external atmosphere could enter freely to fill up the vacancy thus created. But inasmuch as the external air cannot enter, a reduction of pressure will take place, which, according to the law of elasticity by Boyle, must be proportionate to the reduction of volume at constant pressure. The difference of pressure thus created between the bulb and the external atmosphere will be balanced by the column of mercury rising up into the tube, and the elevation to which the mercury attains is a true index of the temperature to which the air in the bulb had been previously heated. This is true with regard to all temperatures, from the lowest to the highest, and the instrument may be termed a universal thermometer. If the bulb could be cooled down to 273° Centigrade below the zero point, it would follow by the law of Charles that the elastic pressure of air would be reduced to nothing, that is to say, the motion of the particles of air, which we call heat, would have ceased, and we should have reached the point of an absolute zero, a point which has been theoretically established also by other means.

Practically, such an instrument would be most inconvenient; its indications would have to be corrected by calculation for barometrical variations; the capacity of the descending tube, which contains air not subjected to variation of temperature, would have to be taken into account, and no reliable observations could be arrived at, without taking special precautions, such as are only within reach of the experimental physicist.

[The other known methods of measuring ordinary and furnace temperatures were here passed in review, and the limits of their application pointed out. They were classified into—

- Thermometers, by expansion of liquids.
- Thermometers, by the expansion of solids.
- Pyrometers, by chemical decomposition of solids, comprising Wedgwood's and Deville's pyrometers.
- Pyrometers, by observing the melting-point of metals.
- Pyrometers, by thermo-electricity.
- Pyrometers, by exposing a copper or platinum ball of known heat capacity to the heat to be ascertained, and of quenching it in a measured quantity of water.]

The instrument which forms the subject matter of my discourse presents many points of analogy with the air thermometer, if we substitute "electrical resistance in conductors" for "expansion of gases." Both these effects are functions of temperature, increasing with the temperature according to progressive laws, which in the case of the gases we call the law of Charles, and in the case of conductors, the law of "increase of electrical resistance with temperature." The latter law, which is of recent origin, had already been partially developed by Arndsen, Swanberg, Lenz, and Werner Siemens, when my attention was directed in 1860 towards an application of the same to the measurement of temperatures at places inaccessible to the ordinary thermometer. By means of the contrivance which I shall describe presently, I was enabled to tell, in the testing cabin of a cable ship, the increasing temperature of the interior of the mass cable in the hold, and to prove the necessity of trans-shipment of the same into a vessel fitted with water-tight tanks, which have been resorted to ever since, to avoid the danger of softening the gutta-percha covering.

I have arranged an apparatus for proving to you in the first instance that the conductivity of a wire of platinum or other metal is greatly influenced by its temperature; for this purpose I direct the current of a galvanic battery at will through two branches of equal resistance, each branch comprising a free spiral wire of platinum and one of the coils of a differential galvanometer. By throwing the powerful light of an electric lamp upon the face of the differential galvanometer, and by throwing the image by means of a mirror and lens upon the screen, the audience will see any movement of the needle to the right or the left that

* Lecture delivered at the Royal Institution of Great Britain, March 1st, 1872, by C. William Siemens, F.R.S.

may take place when I complete the battery connection. The resistance of both branch circuits being the same, no deflection of the needle is observable on depressing the key,

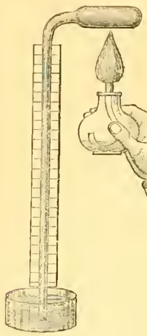

FIG. 1

but when I pass the flame of a spirit-lamp under the one platinum coil, the needle is thrown immediately over to the right, because the electrical resistance of the heated

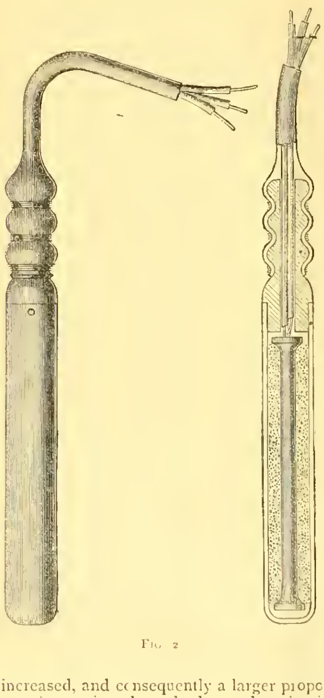

FIG. 2

wire is increased, and consequently a larger proportion of the current is passing through the cooler circuit, exercising a preponderating influence upon the galvanic needle. When I withdraw the spirit flame from the wire the needle rapidly returns to its zero position, but in passing it under the other spiral wire the needle immediately deflects in the opposite direction.

If instead of using the open spirals I were to wind thin insulated wire of any pure metal upon two small cylindrical pieces of wood, and were to enclose the tiny spirals in small silver casings, as shown in view and in section by Fig. 2, taking care that the extremities of the spiral wires were soldered to thicker insulated wires leading respectively to the battery and differential galvanometer before mentioned, it follows that no deflection of the needle ensues when both the protected and equal spirals are dropped into a jar containing iced water. But if I take one of the spirals from the water, and place it, for instance, by his kind permission, into the hands of our President, without disconnecting the same from its leading wires, the balance of resistance will no longer take place, and a deflection of the needle to the right actually takes place. I will now endeavour, however, to re-establish the equilibrium by adding warm water to the iced water surrounding the comparison coil near me until no

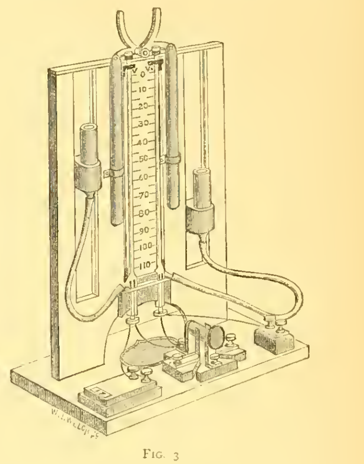

FIG. 3

deflection of the needle is observable. This result being obtained, it follows that the temperature of the water surrounding the one coil must be identical with the temperature of our President's hand, and the delicate mercury thermometer which I have placed in my solution must give me the temperature of the distant place which I intended to measure. The temperature here observed is 89·5° Fahrenheit, which is at this moment that of Sir Henry Holland's hands. This result is independent of the ratio in which the electrical resistance increases with temperature in the similar coils, and considering that the silver casings containing the coils are not larger than small pencil-cases, this method might be advantageously employed in physiological research. The one coil would only have to be placed within the cavity to be measured, to enable the observer to read the temperature from time to time, without disturbing the patient, with the accuracy of which the mercury or spirit of wine thermometer employed is capable. But the same method is applicable for measuring the temperatures of distant or inaccessible places, such as the interior of stores or cargoes of materials liable to spontaneous combustion, of points elevated above the surface of the ground, or of great depths below for

meteorological purposes, or for measuring the temperature of the sea continuously in attaching such a coil to the mariner's sounding lead. An error would in such cases arise, however, through the uncertainty of the resistance of long leading wires, if a complete remedy of error from such a source had not suggested itself. This consists in uniting three separate insulated leading wires into a cable by which the distant coil is connected with the measuring instrument. One galvanic circuit passes from the battery through one of the leading wires, through the distant spiral, and back again through the second leading wire to the differential galvanometer and the battery, and the second passes from the same battery through the near coil, and through the third leading wire up to the distant coil without traversing the same, and back again through the second leading wire to the galvanometer and battery. Thus both galvanic circuits comprise the leading wires up to the distant coil, and all variations of resistance by temperature to which the leading wires may be subjected affect both sides of the balance equally. In constructing coils for measuring deep-sea temperatures a large quantity of insulated copper or iron wire is wound upon a metallic tube open at both ends to admit the sea-water freely in order to impart its temperature to the innermost layers of the insulated wire. The coil of wire is protected externally by drawing a tube of

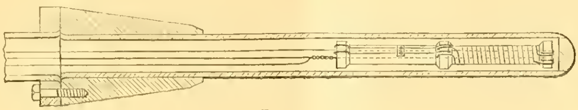

FIG. 4

vulcanised india-rubber over it, which in its turn is bound round by a close spiral layer of copper wire, whereby the sea-water is effectually excluded from the sensitive coil. By these arrangements the temperature of distant or otherwise inaccessible places can be accurately ascertained; but the method is limited to the range of temperature which can be obtained and measured in the comparison bath. In order to realise a pyrometer by electrical resistance, it is necessary to rely upon the absolute measurement of the electrical resistance of a coil of wire which must be made to resist intense heats without deteriorating through fusion or oxidation. Platinum is the only suitable metal for such an application, but even platinum wire deteriorates if exposed to the direct action of the flame of a furnace, and requires an external protection. The platinum wire used has, moreover, to be insulated and supported by a material which is not fused or rendered conductive at intense heats, and the disturbing influence of leading wires had in this case also to be neutralised. These various conditions are very fully realised by the arrangement represented on the preceding diagram, Fig. 4.

Thin platinum wire is coiled upon a cylinder of hard-

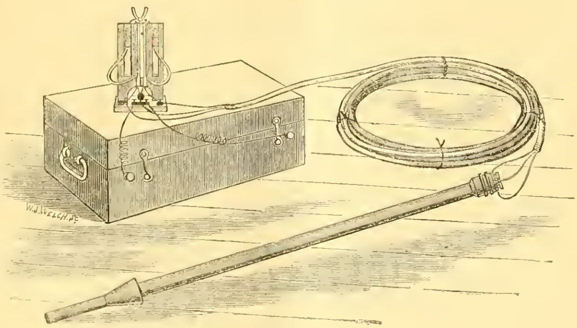

FIG. 5

baked porcelain, upon the surface of which a double-threaded helical groove is formed for its reception, so as to prevent contact between the coils of wire. The porcelain cylinder is pierced twice longitudinally for the passage of two thick platinum leading wires, which are connected to the thin spiral wire at the end. In the upper portion of the porcelain cylinder the two spiral wires are formed into a longitudinal loop, and are connected crossways by means of a platinum binding screw, which admits of being moved up or down for the purpose of adjustment of the electrical resistance at the zero of Centigrade scale. The porcelain cylinder is provided with projecting rims, which separate the spiral wire from the surrounding protecting tube of platinum, which is joined to a longer tube of wrought iron, serving the purpose of a handle for moving the instrument. If the temperatures to be measured do not exceed a moderate white heat, or say 1,300° Centigrade = 2,372° Fah., it suffices to make the lower protecting tube also of wrought iron, to save expense. This lower portion only, up to the conical enlargement or boss of iron, is exposed to the heat to be measured. Three leading wires of insulated copper united into a light cable connect the pyrometer with the measuring instrument, which may be at a distance of some hundred yards from the same. They are connected by means of binding screws at the end of the tube to three thick platinum wires passing down the tube to the spiral of thin platinum wire. Here two of the leading wires are united, whereas the third traverses the spiral, and joins itself likewise to one of the two former, which forms the return wire for two electrical circuits, the

one comprising the spiral of thin wire, and the other returning immediately in front of the same, but traversing in its stead a comparison coil of constant resistance. The measuring instrument may consist of a differential galvanometer as before, if to the constant resistance a variable resistance is added. If the pyrometer coil were to be put into a vessel containing snow and water, the balance of resistance between the two battery circuits would be obtained without adding variable resistance to the coil of constant resistance, and the needle of the differential galvanometer would remain at zero when the current is established. But on exposing the pyrometer to an elevated temperature, the resistance of its platinum coil would be increased, and resistance to the same amount would have to be added to the constant resistance of the measuring instrument, in order to re-establish the electrical balance. This additional resistance would be the measure of the increase of temperature, if only the ratio in which platinum wire increases in electrical resistance with temperature is once for all established. This is a question which I shall revert to after having completed the description of the pyrometric instrument.

Although I have explained that by means of a differential galvanometer and a variable resistance (constituting in effect a Wheatstone bridge arrangement) the increasing resistance of the platinum spiral may be measured, it was found that the use of a delicate galvanometer is attended with considerable practical difficulty in iron-works and other rough places where it is important to measure elevated temperatures, or on board ship for measuring deep-sea temperatures. I was therefore induced to seek the same result by the conception of an instrument which is independent in its action from tremulous motion, or from magnetic disturbance caused by moving masses of iron, and which requires no careful adjustment or special skill on the part of the operator. This instrument is represented by Fig. 3 on page 48, and may be termed a chemical resistance measurer or "differential voltameter." The immortal Faraday has proved that the decomposition of water in a voltameter expressed by the volumes of gases V, is proportionate in the unit of time to the intensity I of the decomposing current, or that

$$I = \frac{V}{T}.$$

According to Ohm's general law, the intensity I is governed by the electro-motive force E, and inversely by the resistance R, or it is

$$I = \frac{E}{R}.$$

It is therefore

$$\frac{V}{T} = \frac{E}{R} \text{ or } V = \frac{ET}{R};$$

or the volume V would give a correct measure of the electrical resistance R, if only the electro-motive force E and time T were known and constant quantities. But the electromotive force of a battery is very variable; it is influenced by polarisation of the electrodes, by temperature, and by the strength and purity of the acid employed. The volume of gases obtained is influenced, moreover, by the atmospheric pressure, and it is extremely difficult to make time observations correctly. It occurred to me, however, that these uncertain elements might be entirely eliminated in combining two similar voltameters in such a manner that the current of the same battery was divided between the two, the one branch comprising the unknown resistance to be measured, and the other a known and constant resistance. The volume of gas V^1 produced in this second voltameter, having a resistance R^1 in circuit, would be expressed by

$$V^1 = \frac{E\,T}{R^1},$$

and we should have the proportion of

$$V : V^1 = \frac{E\,T}{R} : \frac{E\,T}{R^1};$$

or E and T, being the same in both cases, may be struck out, and the expression will assume the simple form

$$V : V^1 = R^1 : R.$$

The constant resistance R of the one circuit being known, it follows that the unknown resistance R^1 is expressed by $\frac{R^v}{V^1}$; that is to say, by a constant multiplied by the proportion of gas produced in the two voltameters irrespective of time, or strength of battery, or temperature, or the state of the barometer.

The resistance R and R^1 are composed each of two resistances, namely, that of the principal coils, which we may term R or R^1, and of the voltameter and leading wires, which is the same in both cases, and may be expressed by y. The expression should therefore be written as follows:—

$$V : V^1 = R^1 + y^1 : R + y,$$

R^1 being the unknown quantity.

The mechanical arrangement of the instrument will be understood from the diagram, Fig. 3; and the whole arrangement of the pyrometer, with its leading wire and resistance measurer, from the general view given in Fig. 5. The voltametric resistance measurer consists of two calibrated vertical tubes of glass of about 3 millimetres diameter, which are fixed upon a scale showing arbitrary but equal divisions. The upper ends of the tubes are closed by small cushions of india-rubber pressed down upon the openings by means of weighted levers, whereas the lower portions of the tubes are widened out and closed by plugs of wood, through which the electrodes in the form of pointed platinum wires penetrate to the depth of about 25 millimetres into the widened portions of the tubes. By a side branch the widened portion of each vertical tube communicates by means of an india-rubber connecting pipe to a little glass reservoir containing acidulated water, and supported in a vertical slide. In raising the weighted cushions closing the upper ends of the vertical tubes, and in adjusting the position of the small reservoirs, the acidulated water will rise in both tubes to the zero line of the scale. In turning a button in front of the tubes the battery current is passed through both pairs of electrodes, the one circuit comprising the permanent resistance R and the leading wires up to the pyrometer, and the other the leading wires and the pyrometer coil. If the resistance of the pyrometer coil should be equal to the permanent resistance R, then $R^1 + y$ will be equal to $R + y$, and therefore $V = V^1$, but as the resistances differ, so will the volumes. Necessary conditions are, that both reservoirs are filled with the same standard solution of pure water with about 10 per cent. of sulphuric acid, that all the electrodes are of the same form and size, and that their polarity is reversed frequently during the progress of each observation, in order to avoid unequal polarisation. With these precautions, which involve no particular skill or knowledge of electrical observation on the part of the operator, very accurate results are obtained; but in order not to incur considerable error of observation, it is advisable not to continue the current, reversing the same, say twice, until at least forty divisions of gases are produced in the least activated tube, which operation will occupy from two to three minutes, if a battery of from four to six Daniel elements is employed. The volumes V and V^1 being noted, after having allowed half a minute for the gases to collect after the current has ceased, the weighted cushions upon the tubes are raised in order to allow the gases to escape, when the water levels will immediately return to their zero position, to make ready for another observation. By inserting the observed values for V and V^1 into the ex-

pression above given, the unknown resistance R^1 can be easily calculated; but in order to facilitate the use of the instrument, I have prepared a table which gives at a glance the resistance due to any two observed volumes, the volumes V governing the vertical, V^1 the horizontal columns, and the resistance being read off at the point of intersection. At each point of intersection the resistance is marked in black, and the corresponding temperature in red ink.

It now remains only to be shown what is the relation between the resistance and temperature in heating a platinum wire. The researches of Dr. Matthiesen, who has made the latest investigations on the effect of temperature upon electrical resistance, are restricted to the narrow range of temperatures between 0° and 100° Centigrade, nor do they comprise platinum. He adopted the following general expression for the pure metals:—

$$R_t = \frac{R_o}{1 + xt + yt^2}$$

which, in determining the specific values of x and y for each metal, gives a close agreement with observation between the narrow limits indicated, but is wholly inapplicable for temperatures exceeding 200° Centigrade, when the value t^2 commences to predominate and to produce absurd values for R_t.

It was necessary for my purpose to undertake a series of elaborate experiments with a view of finding a ratio of general application. Coils of thin wire, of platinum, iron, copper, and some other metals, were gradually heated and cooled in metallic chambers containing the bulbs of mercury thermometers, and for higher temperatures of air thermometers, and the electrical resistances were carefully noted. The progressive increase of electrical resistance was thus compared directly with the increasing volume of a permanent gas (carefully dried) between the limits of zero and 470° Centigrade, and a ratio established which is represented by the formula—

$$R_t = \alpha T^2 + \beta T + \gamma,$$

in which T signifies total temperature counting from the absolute zero, and α, β, and γ specific coefficients for each metal. According to this formula the electrical resistance is a constant at the absolute zero, and progresses in a ratio represented graphically by a tipped-up parabola, approaching more and more toward a uniform ratio at elevated temperatures. Although the comparison with the air thermometer could only be carried up to 470° C., the general correctness of the ratio of increase just stated has been verified by indirect means in measuring progressive heats, and by comparison with the platinum ball pyrometer.

It is important to mention here that great care must be exercised in the selection of the platinum wire for the measuring spiral, platinum wire having been met with conducting only 4·7 times better than mercury at zero C., and others conducting 8·2 times better than mercury, although both samples had been supplied by the same eminent makers, Messrs. Johnson and Mathey. The abnormal electrical resistance of some platinum wire is due chiefly to the admixture of iridium or other metals of the same group, and it appears that the platinum prepared by the old welding process is purer and therefore better suited for electrical purposes than the metal consolidated by fusion in a Deville furnace.

In conclusion, I shall show some working results of the pyrometer in measuring by means of the same protected coil a mixture of ice and water, boiling water, molten lead, and the fire itself by which the lead is melted, the readings produced being 2° C., 98° C., 330° C., and 860° C. respectively. The latter temperature signified a cherry red heat, as may be judged by the appearance of the tube when withdrawn from the fire. The instrument which I have had the honour to bring before you this evening has already received several useful applications. Through its first application an important telegraph cable was saved from destruction through spontaneous generation of heat. Prof. Bolzani, of Kasan, has made some interesting applications of it for recording the temperature at elevated points and at points below the earth's surface. Mr. Lowthian Bell has used it in his well-known researches on blast-furnace economy; and at several iron-works pyrometer tubes are introduced into the heating stoves, and permanently connected with the office, where the heat of each stove can at all times be read off and recorded. These and other applications are sufficiently self-evident, if the soundness of the principles upon which I rely is conceded; but I feel that the shortness of time at my command has hardly enabled me to do more than to pass these in review, while endeavouring to demonstrate the results obtained of recording the temperatures of distant or inaccessible places, including furnace temperatures.

NOTES

THE "Faraday lecture" of the Chemical Society will take place on Thursday, May 30, at 8 o'clock, in the theatre of the Royal Institution, Albemarle Street. This lectureship, founded in honour of the late Prof. Faraday, was inaugurated two years since by a masterly address given by M. Dumas of Paris. Prof. Cannizzaro of Palermo has consented to deliver the lecture this year, which will be anticipated with much interest; he has chosen as his subject "Considérations sur quelques points de l'Enseignement théorique de la chimie."

AT the meeting of the Royal Geographical Society held on Monday evening last, Sir Henry Rawlinson said that the opinion of the Council of the Society was favourable to the authenticity of the intelligence received by telegram respecting Dr. Livingstone. They had every reason to expect that Dr. Livingstone and Mr. Stanley would meet about the beginning of the year. But if there had been any discovery and relief, it was Dr. Livingstone that had discovered and relieved Mr. Stanley, and not Mr. Stanley who had discovered and relieved Dr. Livingstone; because Dr. Livingstone was in clover and Mr. Stanley was absolutely destitute. They knew by the last account that Mr. Stanley was without supplies, and he must have undergone much difficulty in getting to Ujiji; whereas this place was the head-quarters of Dr. Livingstone's supplies. He expected that they would have full letters in the course of a fortnight from Zanzibar, which would inform them on what was known about Dr. Livingstone and Mr. Stanley, and in the meantime he could only say that the telegram was credible.

WE exceedingly regret to have to announce the death, after a short illness (but too probably the effect of overwork), of Mr. George Robert Gray, F.R.S., Senior Assistant Keeper of the Zoological Collections in the British Museum, and an ornithologist of world-wide reputation through his numerous works. Of these we need only particularise two—but two such as have never been executed by any other man—the "Genera of Birds," in three folio volumes (1844-1849), illustrated by the late Mr. Mitchell, some time secretary of the Zoological Society, and by Mr. Wolf, showing an amount of labour at that time unparalleled; and the "Hand-list of Birds," only completed last year, and compiled with a like amount of assiduity. Both these are works found to be indispensable by advanced students of Ornithology in every country; a fact which is alone sufficient proof of their value. The magnificent bird gallery in the British Museum, probably the most popular portion of that building, owes its chief importance to Mr. Gray's labours; and we hope that, in selecting a successor to fill his post, the trustees will not hold themselves bound by any rule of routine, but will take care that the officer in whose charge the splendid collection will be

placed is one whose appointment will command the confidence of ornithologists, not in this country only, but throughout the world.

JUST before going to press we have received the new scheme for the Natural Sciences, prepared by the Board of Studies at Oxford. We can only at present note the publication of this important document, of which we will give the main features next week.

AT the meeting of the French Academy on May 6, MM. Mascart and Janssen were selected to be recommended to the Minister of Public Instruction as candidates for the Chair of General and Experimental Physics at the College of France, vacant by the resignation of M. Regnault.

A MEETING of gentlemen who have within the last fifty years attended the Natural Philosophy class in the University of Edinburgh was recently held, to consider the best means of recognising the long services of Mr. James Lindsay, Experimental Assistant to the Professor of Natural Philosophy. Mr. Lindsay has been connected with the University for the last 58 years, and has acted as Experimental Assistant to the Professor of Natural Philosophy for 53 sessions, serving successively Prof. Sir John Leslie, Principal James David Forbes, and Prof. P. G. Tait. Mr. Lindsay has assisted these gentlemen in their original investigations, and has thus been intimately associated with the progress of physical science in Scotland within the last half-century. All have borne unqualified testimony to his accuracy as an experimentalist. Mr. J. C. Young, of 4, Brighton Place, Portobello, and Mr. James Dewar, of 15, Gilmour Place, Edinburgh, are the secretaries to the committee, and will gladly receive subscriptions in aid of the fund, which, we doubt not, will speedily be collected for so worthy an object.

AT the meeting of the Zoological Society on June 4, Prof. Owen will read a paper upon a new large wingless bird recently discovered in the post-tertiary deposits of Queensland, Australia. Prof. Owen refers these remains to a new genus of *Struthiones*, allied to the Emeu (*Dromæus*), which he proposes to call *Dromornis*.

THE Conversazione of the Society of Arts is fixed to take place at the South Kensington Museum on Wednesday, the 19th of June.

THE President of the Institution of Civil Engineers, Mr. Hawksley, has issued cards of invitation for a conversazione on Tuesday, the 28th inst, in the Western Galleries of the International Exhibition Buildings at Kensington.

DR. HOOKER has just issued his Report of the Royal Gardens at Kew for the year 1871. The number of visitors has not been quite equal to either of the two preceding years; but the director attributes this entirely to the diminished number of those classes whose presence is in every way undesirable: the number of visitors who take an intelligent interest in the gardens and their productions being, he believes, steadily on the increase. The number of Sunday visitors is more than two-thirds of the total number on all the other days of the week; Monday, the "artisans' day," showing considerably the largest numbers of any of the week days, and Dr. Hooker speaks of the almost uniformly orderly conduct of the visitors on this day, contrasting in some instances favourably even with that displayed by some of the fashionable Saturday visitors. In the Botanic Gardens no change of importance has been introduced, except the making of a few more shrubberies, and bringing together various scattered young trees by threes or in clumps, so as to give more extent of lawn in certain parts, and broader masses of foliage in others. The works in the Pleasure Grounds and Arboretum have been almost uninterruptedly continued, and a very large space has been planted, partly with young trees brought from the plantations in the Queen's garden, &c., and partly with smaller things to act as a shelter to these. The interchange of living plants and seeds has been continually kept up with similar establishments abroad and in the colonies; and a gardener has been sent out to Jamaica to re-establish the Botanic Garden there, at the request of the Governor, Sir J. P. Grant.

THE following works, bearing more or less on Science, are announced as in the press:—By Messrs. Longmans—"An Exposition of Fallacies in the Hypothesis of Mr. Darwin," by Mr. C. R. Bree, M.D., F.Z.S., 8vo, with plates; "As Regards Protoplasm," by Mr. J. H. Stirling. New and improved edition, completed by the addition of Part II. in reference to Mr. Huxley's second issue, and a new preface in reply to Mr. Huxley in "Yeast;" and by Messrs. Strahan—"Town Geology," by the Rev. Charles Kingsley.

THE first part has just appeared of the long-expected Flora of British India by Dr. J. D. Hooker, published under the authority of the Secretary of State for India in Council. The territory included in the Flora is that comprised within the British territories in India (including the Malay Peninsula and the Andaman Isles), together with Kashmir and Western Tibet, but excluding Affghanistan and Beluchistan, the plants of which countries are included in Boissier's "Flora Orientalis," and belong to quite another botanical region, that of Western Asia. Of the 12,000 to 14,000 species of flowering plants and ferns belonging to British Indian botany, not a twelfth part has hitherto been brought together in any one general work on Indian plants; the description of the remainder being scattered through innumerable British and foreign journals, or contained in local floras or works on general botany; and a very large number being either very badly described, or not at all. The work is, therefore, one of considerable labour as well as importance, Dr. Hooker being assisted in it by various other botanists. There are a large number of new species described in this part; and the natural orders included in it are Ranunculaceæ, Dilleniaceæ, Magnoliaceæ, Anonaceæ, Menispermaceæ, Berberideæ, Nymphæaceæ, Papaveraceæ, Capparideæ, Resedaceæ, Bixineæ, Violaceæ, and Pittosporeæ, by Dr. Hooker and Dr. Thomson; Cruciferæ by Dr. Hooker and Dr. Anderson; Fumariaceæ by Dr. Hooker; and a part of Polygaleæ by Mr. A. W. Bennett.

THE Annual Report of the Maidstone and Mid-Kent Natural History and Philosophical Society for 1871 refers to the successful attempt made during the year to introduce instruction by means of science classes in connection with the society. The senior classes of all the schools in Maidstone have been enrolled in one great class for the study of Physical Geography, and a class of over 300 pupils, constant in their attendance, receives weekly lectures on this subject. The instruction is given gratuitously by members or officers of the Society, and the apparatus has also been provided or constructed by them. A class is also in operation for the study of Inorganic Chemistry. The Society is by this means performing a most useful function in spreading a love of science among our school-boys.

AN error has been pointed out to us in the article entitled "English Rainfall in 1871" which appeared in our issue of April 18. One inch of rain is computed at 22,500 gallons per acre, instead of, as it should be, $\frac{6,272,640}{277,274} = 22,623$ gallons, or more exactly 22,622·532, per acre. The error applies to columns γ and δ of the table there given, and to the first half of the second paragraph following, the error being equivalent to 123 in every 22,500 gallons. The correct estimate of the rainfall on a square mile during the year is $22,623 \times 640 \times 22{\cdot}42 = 324,612,902$ gallons, or 14,739,053 hectolitres, nearly.

*HISTORY OF THE NAMES CAMBRIAN AND SILURIAN IN GEOLOGY**

(*Concluded from page* 37)

THE Lingula flags and Tremadoc slates have been made the subject of careful stratigraphical and palæontological studies by the Geological Survey, the results of which are set forth by Ramsay and Salter in the third volume of the Memoirs of the Geological Survey, published in 1866, and also, more concisely, in the Anniversary Address by the former to the Geological Society in 1863. (Geol. Jour. XIX. xviii.) The Lingula flags (with the underlying Menevian, which resembles them lithologically) rest in apparent conformity upon the purple Harlech rocks both in Pembrokeshire and in Merionethshire, where the latter appear on the great Merioneth anticlinal, long since pointed out by Sedgwick. The Lingula flags (including the Menevian), have in this region, according to Ramsay, a thickness of about 6,000ft. Above these, near Tremadoc and Festiniog, lie the Tremadoc slates, which are here overlain, in apparent conformity, by the Lower Llandeilo beds. At a distance of eleven miles to the north-west, however, the Tremadoc slates disappear, and the Lingula flags are represented by only 2,000ft. of strata; while in parts of Caernarvonshire and in Anglesea the whole of the Lingula flags and moreover the Lower Cambrian rocks are wanting,† and the Llandeilo beds rest directly upon the ancient crystalline schists. In Scotland and in Ireland, moreover, the Lingula flags are wholly absent, and the Llandeilo rocks there repose unconformably upon grits regarded as of Lower Cambrian age. Thus, without counting the Tremadoc slates, which are a local formation unknown out of Merionethshire, we have (including the Bangor group and Lingula flags) beneath the Llandeilo, over 9,000ft. of fossiliferous strata, which disappear entirely in the distance of a few miles. From a careful survey of all the facts, the conclusion of Ramsay is irresistible, that there exist between the Lingula flags and the Llandeilo not merely one, but two great stratigraphical breaks in the succession; the one between the Lingula flags and the Lower Tremadoc slates, and the other between the Upper Tremadoc slates and the Lower Llandeilo.

This conclusion is confirmed by the fact that there exists at each of these horizons a nearly complete palæontological break. The fauna of the Tremadoc slates is, according to Salter, almost entirely distinct from that of the Lingula flags, and not less distinct from that of the so-called Lower Llandeilo or Arenig rocks (the equivalents of the Skiddaw slates of Cumberland). Hence, says Ramsay, it is evident "that in these strata we have three perfectly distinct zones of organic remains, and therefore, in common terms, three distinct formations." The palæontological evidence is thus in complete accordance with that furnished by stratigraphy. We cannot leave this topic without citing the conclusion of Ramsay, that "each of these two breaks necessarily implies a lost epoch, stratigraphically quite unrepresented in our area; the life of which is only feebly represented in some cases by the fossils common to the underlying and overlying formation." In connection with this remark, which we conceive to embody a truth of wide application, it may be said that stratigraphical breaks and discordances in a geological series may, *a priori*, be expected to occur most frequently in regions where this series is represented by a large thickness of strata. The accumulation of such masses implies great movements of subsidence, which, in their nature, are limited, and are accompanied by elevations in adjacent areas, from which may result, over these areas, either interruptions in the process of sedimentation, or the removal, by sub-aerial or sub-marine denudation, of the sediments already formed. The conditions of succession and distribution, it may be conceived, would be very different in a region where the period corresponding to this same geological series was marked by comparatively small accumulations of sediment upon an ocean-floor subjected to no great movements.

This contrast is strikingly seen between the conformable series of less than 2,000 feet of strata which in Scandinavia are characterised by the first three palæozoic faunas (Cambrian and Silurian) and the repeatedly broken and discordant succession of more than 30,000 feet of sediments† which in Wales are their palæontological equivalents. It must, however, be considered that in regions of small accumulation where, as in Scandinavia, the formations are thin, there may be lost or unrepresented zoological epochs whose place in the series is marked by no stratigraphical break. In such comparatively stable regions, movements of the surface sufficient to cause the exclusion, or the disappearance by removal, of the small thickness of strata corresponding to an epoch, may take place without any conspicuous marks of stratigraphical discordance.

The attempt to establish geological divisions or horizons upon stratigraphical or palæontological breaks must always prove fallacious. From the nature of things, these, whether due to non-deposition or to subsequent removal of deposits, must be local; and we can say confidently that there exists no break in life or in sedimentation which is not somewhere filled up and represented by a continuous and conformable succession. While we may define one period as characterised by the presence of a certain fauna, which, in a succeeding epoch, is replaced by a different one, there will always be found, in some parts of their geographical distribution, a region where the two faunas commingle, and where the gradual disappearance of the old before the new may be studied. The division of our stratified rocks into systems is therefore unphilosophical, if we assign any definite or precise boundaries or limitations to these. It was long since said by Sedgwick with regard to the whole succession of life through geologic time—that all belongs to one great *systema naturæ*. (Philos. Mag. IV. viii. 359)

We have already noticed that Barrande, as early as 1852, gave the name of Primordial Silurian to the rocks which, in Bohemia, were marked by the first fauna; although he, at the same time, recognised this as distinct from and older than the second fauna, discovered in the Llandeilo rocks, which Murchison had declared to represent the dawn of organic life. Into the reasons which led Barrande to include the rocks of the first, second, and third fauna in one Silurian system (a view which was at once adopted by the British Geological Survey and by Murchison himself), it is not our province to inquire; but we desire to call attention to the fact that the latter, by his own principles, was bound to reject such a classification. In his address before the Geological Society in 1842 (already quoted in the first part of this paper) he declared that the discussion as to the value of the term Cambrian involved the question "whether there was any type of fossils in the mass of the Cambrian rocks different from those of the Lower Silurian series. If the appeal to nature should be answered in the negative, then it was clear that the Lower Silurian type must be considered the true base of what I had named the protozoic rocks; but if characteristic new forms were discovered, then would the Cambrian rocks, whose place was so well established in the descending series, have also their own fauna, and the palæozoic base would necessarily be removed to a lower horizon."

In the event of no distinct fauna being found in the Cambrian series, it was declared that "the term Cambrian must cease to be used in zoological classification, it being in that sense synonymous with Lower Silurian." (Proc. Geol. Soc. iii. 641 *et seq.*) That such had been the result of palæontological inquiry Murchison then proceeded to show. Inasmuch as the only portion of Sedgwick's Cambrian which was then known to be fossiliferous, was really above and not below the Llandeilo rocks, which Murchison had taken for the base of his Lower Silurian, his reasoning with regard to the Cambrian nomenclature, based on a false datum, was itself fallacious; and it might have been expected that when the Government surveyors had shown his stratigraphical error, Murchison would have rendered justice to the nomenclature of Sedgwick. But when, still later, a farther "appeal to nature" led to the discovery of "characteristic new forms," and established the existence of a "type of fossils in the mass of the Cambrian rocks different from those of the Lower Silurian series," Murchison was bound by his own principles to recognise the name of Cambrian for the great Festiniog group, with its primordial fauna, even though Barrande and the Government surveyors should unite in calling it Primordial Silurian.

He however chose the opposite course, and now attempted to claim for the Silurian system the whole of the Middle Cambrian or Festiniog group of Sedgwick, including the Tremadoc slates

* Reprinted from advance sheets of the *Canadian Naturalist*.

† The Longmynd rocks in Shropshire are alone estimated at 20,000 feet; but their supposed equivalents, the Harlech rocks of Pembrokeshire, have a measured thickness of 3,300, while the Llanberis and Harlech rocks together, in North Wales, equal from 4,000 to 7,000 feet, and the Lingula flags and Tremadoc slates, united, about 7,000 feet. The Bala group in the Berwyns exceeds 12,000 feet, and the proper Silurian, from the base of the Upper Llandovery or May Hill sandstone, attains from 5,000 to 6,000 feet; so that the aggregate of 30,000 feet may be considered below the truth. (Mem. Geol. Survey, iii. part 2, pages 72, 222, and Siluria, 4th ed. 185.)

and the Lingula flags. The grounds of this assumption, as set forth in the successive editions of "Siluria" from 1854 to 1867, and in various memoirs, may be included under three heads: first, that the Lingula flags have been found to exist in some parts of his original Silurian region; second, that no clearly-defined base had been assigned by him to his so-called system; and third, that there are no means of drawing a line of demarcation between these Middle Cambrian formations and the overlying Llandeilo.

With regard to the first of these reasons, it is to be said that the only known representatives of the Lingula flags in the region described by Murchison in his "Silurian System" are the black slates of Malvern, and some scanty outliers which, in Shropshire, lie between the old Longmynd rocks and the base of the Stiper-stones. The former were then (as has already been shown) supposed by him to belong to the Llandeilo, or rather to the passage-beds between the Llandeilo and Cambrian (Bala); while with regard to the latter, Ramsay expressly tell us that they were not originally classed with the Silurian, but have since been included in it. (Mem. Geol. Sur. iii. part 2, page 9; and 242, foot-note)

The Llandeilo beds were by Murchison distinctly stated to be the base of the Silurian system (Sil. Sys. 222); and it was further declared by him that in Shropshire (unlike Caermarthenshire) "there is no passage from the Cambrian to the Silurian strata," but a hiatus, marked by disturbances which excluded the passage-beds, and caused the Lower Silurian to rest unconformably upon the Longmynd rocks. (Ibid, 256; and plates 31, sections 3 and 6; 32, section 4) But in "Siluria" (1st ed. 47) the two are stated to be conformable; and in the subsequent sections of this region, made by Aveline, and published by the Geological Survey, the evidences of this want of conformity do not appear. Murchison at that time confounded the rocks of the Longmynd with the Cambrian (Bala) beds of Caermarthenshire and Brecon. (Sil. Sys. 416). Hence it was that he gave the name of Cambrian to the former; and this mistake, moreover, led him to place the Cambrian of Caermarthenshire beneath the Landeilo. It is clear that if he claimed no well-defined base to the Llandeilo rocks in this latter (their typical region), it was because he saw them passing into the overlying Bala beds. There was, in the error by which he placed *below* the Llandeilo, strata which were really *above* them, no ground whatever for afterwards including in his Silurian system, as a downward continuation of the Llandeilo rocks (which are the basal portion of the Bala group), the whole Festiniog group of Sedgwick; whose infra-position to the Bala had been shown by the latter long before it was known to be fossiliferous.

It was, however, claimed by Murchison that no line of separation can be drawn between these two groups. The results of Ramsay and of Salter, as set forth in the address of the former before the Geological Society in 1863, and more fully in the Memoirs of the Geological Survey (vol. iii. part 2) published in 1866, with a preface by himself, as the director of the Survey, are completely ignored by Murchison. The reader familiar with these results, of which we have given a summary, finds with surprise that in the last edition of "Siluria," that of 1867, they are noticed in part, but only to be repudiated. In the five pages of text which are there given to this great Middle Cambrian division, we are told that the distinction between the Lower Tremadoc and the Lingula flags "is difficult to be drawn," and that the Upper Tremadoc slate passes into and forms the lower part of the Llandeilo, "into which it graduates conformably" ("Siluria," 4th ed. p. 46). In each of these cases, on the contrary, according to Ramsay, there is observed "a break very nearly complete both in genera and species, and probable unconformity;" the evidence of the palæontological break being furnished by the careful studies of Salter; while that of the stratigraphical break, as we have seen, leaves no reason for doubt. (Mem. Geol. Sur. iii. part 2, pp. 2, 161, 234). The student of "Siluria" soon learns that in all cases where Murchison's pretensions were concerned, the book is only calculated to mislead.

The reader of this history will now be able to understand why, notwithstanding the support given by Barrande, by the Geological Survey of Great Britain, and by most American geologists, to the Silurian nomenclature of Murchison, it is rejected, so far as the Lingula-flags and the Tremadoc slates are concerned, by Lyell, Phillips, Davidson, Harkness, and Hicks in England, and by Linnarsson in Sweden. These authorities have, however, admitted the name of Lower Silurian for the Bala group or Upper Cambrian of Sedgwick; a concession which can hardly be defended, but which apparently found its way into use at a time when the yet unravelled perplexities of the Welsh rocks led Sedgwick himself to propose, for a time, the name of Cambro-Silurian for the Bala group. This want of agreement among geologists as to the nomenclature of the lower palæozoic rocks, causes no little confusion to the learner. We have seen that Henry Darwin Rogers followed Sedgwick in giving the name of Cambrian to the whole palæozoic series up to the base of the May Hill sandstone; and the same view is adopted by Woodward in his Manual of the Mollusca. The student of this excellent book will find that in the tables giving the geological range of the Mollusca, on pages 124, 125, and 127, the name of Cambrian is used in Sedgwick's sense, as including all the fossiliferous strata beneath the May Hill sandstone. On page 123 it is however explained that Lower Silurian is a synonym for Cambrian, and it is so used in the body of the work.

The distribution of the Lower and Middle Cambrian rocks in Great Britain may now be noticed. The former, or Bangor group, to which Murchison and the Geological Survey restrict the name of Cambrian, and which they sometimes call the Longmynd, bottom or basement rocks, occupy two adjacent areas in Caernarvon and Merionethshire; the one near Bangor, including Llanberis, to the north-east, and the other, including Harlech and Barmouth, to the south-east of Snowdon; this mountain lying in a synclinal between them, and rising 3,571 feet above the sea. The great mass of grits or sandstones appears to be at the summit of the group, but in the lower part the blue roofing slates of Llanberis are interstratified in a series of green and purple slates, grits, and conglomerates (some of the Welsh roofing-slates are, however, supposed to belong to the Llandeilo). (Mem. Geol. Survey iii. part 2, pages 54, 258). The Harlech rocks in this north-western region are conformably overlaid by the Menevian, followed by the true Lingula-flags, or Olenus beds, of the Middle Cambrian. Upon these repose the Tremadoc slates, which are not known in the other parts of Wales. The third area of Lower Cambrian rocks is that already described at St. David's in Pembrokeshire, about 100 miles to the south-west; and the fourth, that of the Longmynd hills, about sixty miles to the south-east of Snowdon. The rocks of the Longmynd, like those of the other Lower Cambrian areas mentioned, consist principally of green and purple sandstones with conglomerates, shales, and some clay-slates. They occasionally hold flakes of anthracite, and small portions of mineral pitch exude from them in some localities. The only evidence of animal life yet found in the rocks of the Longmynd is furnished by worm-burrows, the obscure remains of a crustacean (the *Palæopyge Ramsayi*) and a form like *Histioderma*. This latter organic relic, with worm-burrows, and the fossils named *Oldhamia*, is found on the coast of Ireland opposite Caernarvonshire, in the rocks of Bray Head; which resemble lithologically the Harlech beds, and are regarded as their equivalents.

Still another area of the older rocks is that of the Malvern hills, on the western flanks of which, as already mentioned, the Lingula flags are represented by about 500 feet of black shales with *Olenus*, underlain by 600 feet of greenish sandstones containing traces of fucoids, with Serpulites and an *Obolella*. It is not improbable, as suggested by Barrande and by Murchison, that these 1,100 feet of strata represent, in this region, the great mass of the Lingula flags, and, we may add, perhaps the whole series of Lower Cambrian strata, which in Caernarvonshire and Pembrokeshire underlie them; since these sandstones of Malvern, like those of St. David's, rest upon crystalline schists, and are in part made up of their ruins.

These crystalline schists of Malvern, which are described by Phillips as the oldest rocks in England, and by Mr. Hull are conjectured to be Laurentian, seem, from the descriptions of their lithological characters, to resemble those of Caernarvon and Anglesea, with which they are, by Murchison, regarded as identical. The crystalline schists of these latter localities are by Sedgwick described as hypozoic strata, below the base of the Cambrian. Murchison, however, in the first edition of his "Siluria," adopted the suggestion of De la Beche that they themselves were altered Cambrian strata. In fact, they directly underlie the Llandeilo rocks, and were apparently conceived by Murchison to represent the downward continuation of these, upon which he had insisted. This opinion is supported by ingenious arguments on the part of Ramsay (Mem. Geol. Survey, iii. part 2, *passim*). I am however disposed to regard them, with Sedgwick and Phillips, as of pre-Cambrian age, and to compare them with the Huronian series of North America, which occupies a similar geological

horizon, and with which, as seen in northern Michigan, and in the Green Mountains, I have found the rocks of Anglesea to offer remarkable lithological resemblances.

It may here be noticed that the gold-bearing quartz veins in North Wales are found in the Menevian beds, and also, according to Selwyn, throughout the Lingula flags. These fossiliferous strata at the gold mine near Dolgelly appear in direct contact with diorites and chloritic and talcose schists, which are more or less cupriferous, and themselves also contain gold-bearing quartz veins (Mem. Geol. Survey, part 2, pp. 42, 45, and Siluria, 4th ed., 450, 547).

The following table gives a view of the lower palæozoic rocks of Great Britain and North America, together with the various nomenclatures and classifications referred to in the preceding pages. In the second column, the horizonal black lines indicate the positions of the three important palæontological and stratigraphical breaks signalised by Ramsay in the British succession (Mem. Geol. Survey, iii. part 2, page 2). In a table by Davidson in the *Geological Magazine* for 1868 (v. 305) showing the distribution of organic remains in these lower rocks, he gives, as the Festiniog group of Sedgwick, only the Dolgelly and Maentwrog beds of Belt (the Upper and Middle Lingula flags), and makes of the two divisions of the Tremadoc rocks a separate group; the whole being described as the Upper Cambrian of Sedgwick. This, however, is not the present grouping and nomenclature of Sedgwick, nor was it his earlier one. So far as

LOWER PALÆOZOIC ROCKS OF EUROPE AND NORTH AMERICA

	British Sub divisions.	North American Sub-divisions.	Nomenclatures of Sedgwick and Murchison.	Barrande's Classification.	Angelin's Divisions.
14	Ludlow.	Lower Helderberg.	Silurian, *Sedgwick.* Upper Silurian, *Murchison.*	Third fauna, including Etages H, G, F, E.	VIII. VII., or Regiones E, and DE.
13	Wenlock.	Niagara, Clinton,			
12	Upper Llandovery.	Medina, Oneida.			
11	Lower Llandovery.	Hudson-River, Utica,	Upper Cambrian or Bala group, *Sedgwick.* Lower Silurian, *Murchison.*	Second fauna, including Etage D.	VI. V. IV., or Regiones D, C, and BC.
10	Caradoc.	Trenton, Birdseye,			
9	Upper Llandeilo	Black-River.			
8	Lower Llandeilo.	Chazy.			
7	Upper Tremadoc.	Levis.	Middle Cambrian or Festiniog group, *Sedgwick.* Primordial Silurian, *Murchison.*	First fauna, or Primordial fauna, including Etage C, and probably also Etage B.	III. II. I., or Regiones B, and A, and Regio Fucoidarum.
6	Lower Tremadoc.	Calciferous.			
5	Dolgelly.	Potsdam.			
4	Maentwrog.

2	Harlech.	——— ?			
1	Llanberis.	——— ?			

regards Middle and Upper Cambrian, this discrepancy is explained by the fact already stated, that in 1843 Sedgwick proposed as a compromise the name of Cambro-Silurian for his Bala group, previously called Upper Cambrian; by which change the Festiniog or Middle Cambrian became Upper Cambrian. When the true relation between the Lower Silurian of Murchison and the Bala group was made known, Sedgwick, as we have seen, re-claimed for the latter his former name of Upper Cambrian; but this had meanwhile been adopted for the Festiniog group, in which sense it is still used by Lyell, Phillips, Davidson, Harkness, and Hicks. The Festiniog group, or Middle Cambrian, as defined by Sedgwick, however, included not only the whole of the Lingula flags, but the Upper and Lower Tremadoc rocks (Philos. Mag. IV. viii, 362).

The only change which I have made in the groupings of the British rocks adopted by Sedgwick and by Murchison, is in separating the Menevian or Lower Lingula flags from the Festiniog, and uniting it with the Bangor group or Lower Cambrian. In this I follow, with Lyell and Davidson, the suggestion of Salter and Hicks.

In the third column, the sub-divisions are those of the New York and Canada Geological Surveys; in connection with which the reader is referred to a table published in 1863, in the "Geology of Canada," p. 932. Opposite the Menevian I have placed the names of its principal American localities, which are Braintree, Mass., St. John, New Brunswick, and St. John's, Newfoundland. With regard to the classification of Angelin, it is to be remarked that, although he designates II. as *Regio Olenorum*, and III. as *Regio Conocoryphorum*, the position of these, according to Linnarsson, is to be reversed; the Conocoryphe beds with *Paradoxides* being below, and not above, those holding *Olenus*. The *Regio Fucoidarum* in Sweden has lately furnished a brachiopodous shell, *Lingula monilifera*, besides the curious plant-like fossil, *Eophyton Linnæanum*. (Linnarsson, Geol. Mag., 1869, vi. 393.)

T. STERRY HUNT

SOCIETIES AND ACADEMIES

LONDON

Zoological Society, May 7.—Prof. Newton, V.P., F.R.S., in the chair. The secretary read a report on the additions that had been made to the society's collection during the month of March, 1872, amongst which were two red-necked bustards (*Eupodotis denhami*), presented by Mr. C. D. O'Connor and Governor Ussher, and a Beatrix antelope (*Oryx ebatrix*) from the Persian Gulf, received on deposit.—Mr. P. L. Sclater exhibited and made remarks on a skull of the Hairy Tapir of the Andes (*Tapirus roulini*) obtained by Mr. Buckley during his recent expedition to Ecuador.—Prof. Owen read the eighteenth of his series of memoirs on the extinct birds of the genus Dinornis and its allies, in which was contained the description of the pelvis and bones of the leg of *Dinornis gravis*, a supposed new species allied to *D. crassus*, and a general *résumé* of the described species of the genus *Dinornis*.—The Viscount Walden, F.R.S., communicated an appendix to his paper on the birds of Celebes, read at a former meeting of the society, and containing an account of twelve species to be added to the Celebean Avifauna. This raised the total number of known species of Celebean birds to 205.—Mr. Henry Buckley exhibited the eggs of three species of North American birds, which he believed had never previously been obtained. The eggs were those of *Falco polyagrus*, *Elanoides furcatus*, and *Ictinia Mississippiensis*.—Mr. H. E. Dresser exhibited the egg of *Querquedula marmorata*, collected in Spain by Major Irby, this being probably the first authenticated instance of the breeding of this bird in Spain.—A communication was read from Mr. W. H. Hudson, containing field notes on the habits of the swallows, of the genus *Progne*, met with in the Argentine Republic. To this was added some notes on the species by Mr. P. L. Sclater.—A communication was read from Mr. G. French Angus, containing descriptions of ten new species of land and marine shells, mostly from Australia.—A second communication from Mr. Angus contained the description of a new species of *Voluta*, proposed to be called *Voluta hargravesi*.—A paper by Mr. H. Adams was read, in which he described a new species of *Geotrochus* from the Island of New Britain, proposed to be called *G. fergusoni*.—A communication was read from Dr. J. E. Gray, F.R.S., containing a description of *Peltastes forsteni*, a species of land tortoise from Celebes.—Two communications were read from Mr. J. M. Brazier, giving descriptions of land and marine shells collected in Australia and Lord Howe's Island.—A communication was read from Mr. A. Anderson, containing some additional notes on the Raptorial birds of North Western India.—A paper by Dr. J. E. Gray, F.R.S., was read, describing a young Tapir from the Peruvian Amazons, which he proposed to call *Tapirus terrestris peruvianus*.—A communication was read from Dr. J. E. Bowerbank, F.R.S., containing the third part of his contributions to a general history of the *Spongiadæ*.

Entomological Society, May 6.—Mr. H. T. Stainton, F.R.S., vice-president, in the chair.—Mr. E. Saunders exhibited a series of species of Australian *Buprestidæ*, illustrating the great sexual differences existing in these insects. Mr. F. Smith exhibited a large collection of *Hymenoptera*, chiefly *Aculeata*, sent by Mr. G. Lewis from Hiogo in Japan. The whole collection was strikingly European in its aspect, though the species were in most cases different; the genera were all represented in Europe save one genus of ants.—Mr. Verrall exhibited an example of *Syrphus lasiophthalmus* with a peculiar malformation of two tibiæ, which appeared as though they had been broken, probably when the insect had just emerged from the puparium, and badly united afterwards.—Mr. Stainton exhibited an aspen leaf, sent by Lord Walsingham from Oregon, pierced by a multitude of small oval holes, caused by small mining micro-lepidopterous larvæ, which each detached an oval case formed of the cuticles of the leaf. These cases had produced a minute moth of the genus *Aspidisca*, which he also exhibited.—Mr. E. Saunders read "Descriptions of twenty new species of *Buprestidæ*."—Mr. H. W. Bates read a memoir on the Longicorn *Coleoptera* of Chontales, Nicaragua; enumerating 242 species sent home by Mr. Belt, and describing the new forms. This collection elicited two general facts—firstly, the homogeneity of the insect fauna of the forest region of tropical America, over, probably, 45 degrees of latitude, and, secondly, the existence of a distinct northern element, whose metropolis is Central America.

Chemical Society, May 2.—Dr. Frankland, F.R.S., president, in the chair. Mr. E. Riley delivered his lecture on the Manufacture of Iron and Steel. The lecturer in his discourse treated of the influence of the elements associated with iron in the pig, and the part they play in the subsequent conversion of pig into wrought-iron and steel. Although in certain districts there is not much variation in the pig made, the same ore and fuel being constantly used, yet in others, as South Wales and Staffordshire, so many varieties of ore are employed that pig of all descriptions is produced. From the results of the analysis of samples of Yorkshire hot-blast pig (No. 1 to 6 iron) from the same works, it would appear that whilst the phosphorus is almost constant in all the kinds, namely, about 0 9 per cent, the quantity of sulphur decreases and that of silicon increases with the number. It is possible that the differences in the amount of sulphur present would explain the differences in the quality of the pig, for it is certain that sulphur makes grey iron white; but, at the same time, the different numbers of grey iron may be produced by differences in the rate of cooling. On examining the pigs from which the best wrought-iron is made, they will be found to contain silicon and phosphorus. Swedish iron, which contains no phosphorus and but little silicon, when used by itself, gives red short iron. It will be seen from this that silicon and phosphorus play an important part in the manufacture of iron. Hæmatite pig frequently contains as much as 4 or 5 per cent. of silicon. The chief constituents of pig-iron are, besides iron, carbon, silicon, sulphur, phosphorus, and manganese, traces of copper and titanium (the latter only in grey iron), frequently nickel and cobalt, and occasionally vanadium and arsenic. The per-centage of carbon in pig iron varies from 3 to 4 per cent., but the question as to whether it forms any definite compound with iron is open to great doubt. Mr. Snelus has shown that by sifting out the finer portions from the borings of Middlesboro' pig a material could be obtained containing 7 per cent. of carbon, and by elutriation one containing more than 41 per cent. The sulphur seems always to be derived from the sulphide of iron present in the fuel or ore, but from some experiments it would seem that an excess of lime may act on the sulphide in the coke and convert it into sulphide of calcium and metallic iron. Silicon is always present to a greater or less extent in iron. With respect to phosphorus, practically speaking, all that is present both in the ore and in the fuel passes into the iron. After some remarks on the comparatively small value of titanium as an ingredient of iron, the speaker discussed the quality and composition of the fuel employed in smelting, and then passed on to the process of refining. The time required for this seems to depend on the quantity of silicon present in the pig, much of it being separated during the operation, along with some sulphur and phosphorus, and a little carbon. The process of puddling was then described, and the merits of the various machines for superseding manual labour discussed, with especial reference to the results obtained with that of Mr. Danks; the great advantage of machine puddling being the uniform quality of the wrought-iron made. In conclusion the author made some remarks especially with reference to the occurrence of silicon in steel. This elaborate and exhaustive memoir was copiously illustrated by analyses.

THE OXFORD SCHEME OF NATURAL SCIENCE *

ALL true lovers of English science, we might say all discerning lovers of their country, must have watched with anxious interest the efforts which in these latter times a few able and energetic men at each of our ancient universities have been making to strengthen and widen the study of Natural Science in those so-called seats of learning; and must have admired the zeal and wisdom with which they have fought against the stubborn resistance of the powers that be. To all such the recently-issued programme of the Board of Natural Science Studies at Oxford will have particular interest; for upon the wisdom of the regulations introduced by that Board will depend in great measure the future of Natural Science at Oxford.

In calling attention to this programme we shall so far rely on our well-known admiration of the talents and energy of the members of the Board as to take leave to say nothing of its good points. These will be read and known of all men who love science; and the results of the scheme, as far as its good features are concerned, will be the reward of its framers, whether, as we hope, they succeed in establishing Natural Science at Oxford in its proper dignity and power, or whether, as we fear, they eventually succumb to all those many influences which seem slowly but surely to be pressing the life out of both Oxford and Cambridge.

We think we shall be best furthering the interests of Science if we content ourselves with pointing out the blots of the scheme, blots which stand out in the stronger relief the more one dwells on what ought to be its immediate results, viz., the destruction of mere cram-work and the encouragement of the spirit of original research.

We learn that the student who wishes to take honours in Natural Science, must undergo a previous examination in the elements of Mechanics, Physics, and Chemistry. We have no remark to make on this, except to suggest that if the elements of Biology had been added, matters would have been vastly simplified, and much of the confusion to which we shall have presently to refer entirely done away with.

Having passed this previous examination, the student may elect to be examined in either Physics, Chemistry, or Biology, with or without certain special subjects, such as Geology, Zoology, or Botany.

Touching the examination in Physics we will simply express our regret that there is no definite statement that the examination in this branch will be partly of a practical kind. This is of course intended, but it is not specially stated. If the distinguished Oxford Professor of Experimental Physics knew what hard work his friends had to persuade the world that his superb laboratory is a real honest workshop, and not a gorgeous palace and magnificent show-room, he would have had the instructions touching the practical part of the examination in Physics printed in capitals or italics rather than omitted altogether.

* Notice of the Board of Studies for the Natural Science School of the University of Oxford, 1872.

With regard to the Chemistry we will only remark that the restriction of the practical part of the examination to the old-fashioned inorganic analysis seems to us to mark an opportunity lost. Is the detection and estimation of a base and an acid for ever to remain the be-all and end-all of practical chemistry? We trust not. A change in this respect must soon take place in our examining bodies, and Oxford might have led the way.

It is to the biological part of the scheme that we desire more particularly to call the attention of our readers. The student who wishes to go out in Biology may take the general subject of Biology either alone or together with certain restricted special subjects, such as Comparative Osteology, Ethnology, &c., or together with either of the larger special subjects, Zoology, Botany, and Geology. The general subject of Biology comprises General and Comparative Anatomy and Histology, both animal and vegetable, Human and Comparative Physiology, with Physiological Chemistry, and "the general philosophy of the subject." Our readers will naturally wonder what is meant by this last heading. They probably have been accustomed to consider that science is philosophy, and that the philosophy, for example, of comparative anatomy, grows out of the facts organically, is borne by the subject as plants bear flowers and fruits, and cannot be pinned on, like an artificial blossom on a garland, either in an examination or elsewhere. The mystery disappears when we turn to the list of books recommended (about which we shall have a word to say), where we find under the head of Genera Philosophy Agassiz' "Classification" and Whewell's "Inductive Sciences." Evidently the Board desires to try the students as the saints of old were tried in order to be made perfect; they tempt them with courses of evil reading to see whether the truth be in them or no. But to return: the scheme, as it stands at present, does very well for a man who goes in for the general subject of Biology on the strength of his acquaintance with the contents of the Oxford Museum, and his knowledge of that Physiology falsely so called which is built up on a comparison of the organs of one animal with those of another. The practical examination in dissections and histological preparations will most likely fairly test his proficiency in these matters, and if he takes up one of the minor special subjects he will probably have a good but limited idea of one particular series of facts, *e.g.*, the various forms of stomach presented by the animal kingdom. We doubt very much if the examination and preparatory course of study will have helped to make him a fruitful man of science, working in and for ideas. Probably the reverse.

But how much better off is he than the poor botanist who goes to seek at Oxford the means and help to make a working man of science of himself. He must first go through the general examination in Biology, must cram up text-books on Human Physiology, must read up all the futilities of the modern animal histologists, and dabble in the speculations of physiological chemists, to say nothing of his knowledge of the exoskeleton of the Arthropoda and other bits of special animal morphology, before he can turn to his heart's desire, the classification of Phanerogams. And he will cram; that will be the inevitable result.*

* The prolixity of some members of the Board seems to have driven the framer of the section of Botany into the opposite extreme. We cannot think it intended that the examination in Botany should be so feeble as the programme seems to intimate.

Hardly better off is the physiologist, properly so called. What he needs as general education is a thorough knowledge of physics and chemistry, with a general acquaintance with the fundamental laws and simpler facts of animal morphology. Instead of that, this scheme takes him away from physics and chemistry, and tries to smother him with the specialities of morphology, to which he most probably has a decided natural repugnance.

Worst off of all is the geologist, who has to go in for all three general subjects before he can make his special knowledge weigh with examiners, and who therefore will be induced to keep on cramming heterogeneous knowledge up to the last moment; forasmuch as the statutes tell him that his place will depend "*on the joint result of his examination in all his subjects*."

In our humble opinion it would have been far better to have made the previous examination to include the elements of Biology, and at the same time rather more searching as a whole. Every science scholar would then have known something of everything essential in Natural Science. Freed by this examination, he might have turned at once to that something of which he ought to know everything—to Geology, to Botany, to Animal Morphology, to Physiology, to Chemistry, to Physics. He would thus have, on the one hand, a sound foundation, with an insight into "the general philosophy," properly so called, of all science, and by early training in a special branch would have had his face set towards original work. We have no space left to criticise the various items of the special directions under Biology, Geology, &c.; but we cannot refrain from uttering our protest against the pernicious habit, carried to an excess in this programme, of recommending particular books for study. This always means "particular books for examination," and is the most potent nurse of cram. Nor is the evil mended much by making the list of books large and long; for rather another evil is then introduced, viz., that of giving authoritative sanction to bad books. We venture to assert that no man of science can look through the list of books appended in this programme to his own particular line without being compelled to admit that some of the books recommended are essentially bad. We have spoken freely because the matter is one we have at heart. We must confess that the scheme at Oxford, as it stands at present, is inferior to that at Cambridge (excepting always that fearful system of order of merit, which hangs like a millstone round all Cambridge studies), and decidedly inferior to what the scientific examinations of the University of London will be when some necessary changes have been made in its B.Sc.

MÄDLER'S HISTORY OF ASTRONOMY

Geschichte des Himmelskunde, nach ihrem gesammten Umfange, von Dr. J. H. von Mädler, Emeritirtem Professor und Director der Sternwarte, Dorpat. 1 Band, i. ii. iii. Lieferungen. (Braunschweig, 1872. London: Williams and Norgate.)

A PERIOD when the love of astronomical study—long confined to a few select votaries, and dormant in general estimation—has attained an unprecedented and unlooked-for diffusion, is well suited for the appearance of such a historical view of the subject as may not only form a book of reference and comparison for the more advanced cultivator of the science, but may commend itself to the less instructed student, as well by the accuracy of its statements as by the perspicuity of its views and the simplicity of its expression. The work of which the earlier portion is now lying before us, seems, as far as can be foreseen, well calculated to answer this end, and Germany may be congratulated upon the commencement, at least, of what, ere long, ought to be made popularly accessible among ourselves. We possess, indeed, already, in the "History of Physical Astronomy," by Prof. Grant, a work of the highest pretension as to accuracy and intelligence; but the subject is there regarded from a different point of view, and treated in a different manner, and there is abundant room for each of them.

For those who venerate the Observatory of Dorpat, from the high position which it took and maintained under the elder Struve, as well as for those who love to contemplate and examine in detail the wonderful features of our satellite, this work will possess a double interest, both as originating within the walls of that honoured building, and as proceeding from the pen of the leading selenographer of his own time. It is only to be hoped that the advancing years of the venerable author may not interrupt the progress of what has been so auspiciously begun. At present it has been carried only as far as the establishment of Tycho *de* Brahe, as it seems to be the inaccurate custom of the Germans to call that great man, in his island of Hween, where "lived the Prince of Astronomy in external fitness, with princely aspect and splendour." But before the science had attained this due recognition as worthy of royal patronage and aristocratic cultivation, it is needless to say that it had to pass through long periods of darkness and discouragement and difficulty, when its progress was retarded by superstitious bigotry, chilled by heedless indifference, or entangled by the substitution of imaginary hypotheses for the patient labour of protracted investigation; and in tracing through all these impediments its gradual and interrupted advance, the learned author has shown not only a full command of the subject, but great fairness and discrimination in its treatment; and if it might be hinted that the style is sometimes encumbered by a repetition of unvaried metaphors, yet it is always perspicuous and pleasing. The only point as to which positive censure would not be invidious is no fault of the author, but of the corrector of the press, who must be held answerable for some offensive errata in the Greek and Latin citations. For errors in English and Welsh, through which Bradley's benefices of Bridstow, in Herefordshire, and Llanddewi-velvre, in Pembrokeshire, appear as "Bradstone" and "Welfric," some intermediate authority must be responsible; but we may fear that our own rendering of German names is not invariably more accurate. In order not to interrupt the current of the history, much of the biographical matter appears in the form of notes at the foot of the page, frequently of especial interest; we feel, however, the want of occasional references. The intensity of the author's annoyance at the monkish system may possibly lead some readers to an occasional smile; but with the Papacy as a whole no religious difference has prevented him from dealing with the candour and justice of a true historian. Of Pliny's merits he has formed a very unfavourable judg

ment, and from this or some other cause, has not noticed a passage in that writer which seems to have been singularly overlooked, but which nevertheless possesses a certain degree of interest. It has been invariably asserted that Hipparchus was incited to the formation of his celebrated catalogue by the appearance of a new star, leaving it to be inferred that it was an object similar to the Great Star of 1572 (the possible return of which, by the way, Baron von Mädler refers to 1885, instead of the present year, as has been sometimes thought), or that of 1604. But it seems to have altogether escaped notice that the words of Pliny in reference to it expressly describe a movement which must have placed it in another class of bodies :—"Novam stellam et aliam in ævo suo genitam deprehendit: ejusque motu, qua die fulsit, ad dubitationem est adductus, anne hoc sæpius fieret, moverenturque et eæ, quas putamus affixas." Such is his statement; where he obtained it of course cannot now be ascertained; but from its explicitness it certainly carries at least a show of authority.

In adopting a more favourable idea of Ptolemy than has been admitted by many opponents of his system, the author has expressed an opinion well deserving of attention :—"When criticising the literary proceedings of Ptolemy, we should not forget how extremely different, as compared with our own, was the form which the mutual relation of authors took in those days. Instead of the hundreds of thousands, or even millions, of books which fill our libraries and catalogues, their number at that time might hardly amount to a thousand; the principal works especially were so few in number that every one, generally speaking, who read and wrote was acquainted with them. Ptolemy wrote for his own time. When he alleged anything which was the property of another without mentioning his name, nobody could then have been well deceived by it, and there could be no reasonable question of a design of plagiarism." And as an incidental parallel he remarks the use made in a similar manner by St. Paul of the expressions of Archias and Epimenides.

Some interesting, but perhaps not generally known, facts may find a suitable place in the present brief notice; such as the discovery on the site of what is conjectured to have been Cicero's house at Rome of a sun-dial, which may have been the identical one mentioned in one of his letters; the employment, in Seneca's time, of hollow glasses filled with oil to protect the eye in observing solar eclipses; the grandeur of speculation which led Cleomedes, some fifteen centuries ago, to assert that the earth would show but as a point to the sun, and from the fixed stars, even if it possessed intrinsic light, would be imperceptible; the discovery in Egypt, in 1854, of four wooden tablets covered with plaster, containing astronomical calculations—the almanac, in fact, of the great school of Alexandria in the reigns of Trajan and Hadrian; the recognition of Uranus by the ancient inhabitants of Tahiti. Relations such as these lend an additional interest to a narrative which, even without them, would not be felt as dry or tedious.

One more passage may be cited, as giving full evidence of that soundness of thought and feeling which thus (but not thus only) are shown to be united in the Baron von Mädler with the other qualifications of a historian :—

"If in those times a comet appeared, writings appeared immediately, especially in the form of religious exhortations, taking occasion from it to recommend repentance and amendment. Let no one suspect that we have even the slightest objection to offer to these admonitions. Much rather could we wish that at other times also, whether a comet were visible or not, they were employed with equal earnestness, and that the inscription on a comet medal of that date (1472)—

God grant us from this comet-blaze
To learn amendment of our ways—

were more laid to heart, especially as regards the second line. If cometary prediction had brought nothing worse to light than exhortations to amendment, we might with respect to this fancy (though the fancy itself, as such, would always remain objectionable) have been able to contemplate the whole with greater satisfaction."

T. W. WEBB

OUR BOOK SHELF

Botany for Beginners: an Introduction to the Study of Plants. By Maxwell T. Masters, M.D., F.R.S. (London: Bradbury, Evans, & Co., 1872.)

THIS is in no sense a cram-book. To take the trouble of learning it by heart, page for page, would not suffice for any botanical examination with which we are acquainted. This is a great advantage in an elementary scientific work. Not only does it enable the author to be entirely independent of the favourite points of particular examiners; but it permits him to pursue his own method of developing the subject in the learner's mind. In no science is this freedom of greater value than in botany. The text-books used and recommended by many teachers of botany would appear to have been especially designed to deter the intending student from the study of the science. Bristling at the outset with a formidable array of technical terms, which should never be introduced till a later stage of the instruction, they give a superficial countenance to the idea which is prevalent even with many who ought to know better, that Botany is a mere science of terms, unworthy to be placed by the side of Comparative Anatomy or Animal Physiology. Each teacher will no doubt have his own idea of the arrangement of his subject best calculated to interest the beginner, and to lead him on step by step to see the true dignity of the science. Dr. Masters's is recommended by his own experience as a lecturer for many years to one of our Metropolitan hospitals. He commences by taking in succession a series of flowers in the order in which they are to be met with as the spring unfolds—willow, poplar, ash, elm, tulip, hyacinth, apple, lilac, and so forth; and in plain and attractive language, bringing in technical terms at the outset only when necessary for the sake of accuracy, he explains the structure of their different parts, and the points in which they resemble or differ from one another. The more important phenomena of the physiology of plants are also brought under review as the descriptions of structure naturally lead up to them, though we think that more space might with advantage have been bestowed on this portion of the subject. A single page devoted to the decomposition of carbonic acid by the leaves, and twelve lines to the process of fertilisation of the ovule, are hardly sufficient to introduce the reader to these branches of physiology, which are not only of the highest importance themselves, but also of far greater interest to the student, if simply and intelligently brought before him, than the details of morphology or of classification. The substance of this little book has already appeared in the columns of the *Gardener's Chronicle*, and it is well illustrated with capital wood-cuts. We heartily recommend "Botany for Beginners" to teachers or parents who are desirous of interesting young persons in this science, and who can appreciate the value of a clearly-written, simple, and yet accurate elementary treatise.

A. W. B.

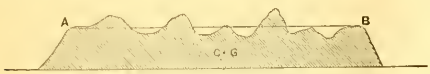
LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Error in Humboldt's Cosmos

THE following letter, from Major-General Sir Henry James, is addressed to Mr. J. Carrick Moore in reference to his communication which appeared in our columns under date April 18.

"I am much obliged to you for sending me NATURE, with your letter in it respecting the manner in which Humboldt has used the term 'Centre of Gravity of the Land,' by which he so far misled Herschel as to make him double the height of the mean elevation of the several continents. It is obvious that Humboldt determined the mean height of their surfaces, and not the height of the centres of gravity of the continents. He determined the height of A B, not of C G. The centres of gravity are, therefore, at half the heights given by Humboldt.



"I have the mean elevation of the surface of Forfarshire determined by the same method explained by you, and by which Humboldt determined the mean elevation of the surfaces of the continents; it was 856 feet above the mean level of the sea. The mean height of the surface of Europe (not of the centre of gravity) is, according to Humboldt, 671 feet, and this is quite as high as I should have expected it to be from the known height of Forfarshire, containing so large an amount of mountainous country. The mean height of the surface of Europe cannot be double this, or 1,042. The height of the water-shed between the Baltic, Black, and Caspian seas is only 1,100 feet.

"I think, therefore, both from the method of investigation and from the results, that you have taken a correct view of the subject, and that you have done science a great service in pointing out the error into which Humboldt has fallen, and by which he misled Herschel to so great an extent.

"John Carrick Moore, Esq." "HENRY JAMES
Southampton, April 22

Fertilisation of Dictamnus

AN arrangement for the distribution of the pollen of *Dictamnus Fraxinella*, which I noticed last June, may interest some of the botanical readers of NATURE. The plants will shortly be in flower, so that any one who is curious about the matter can see it for himself.

To suck the nectar of these flowers, bees stand upon the filaments, which are nearly horizontal; as the anthers are matured they are brought up in turn, generally two at a time, by the curving filaments, into such a position that they rub against the tail of a bee standing on the filaments. As soon as each pair of anthers is emptied they retire, and give place to another pair, and when the last are emptied the style curves up, and brings the stigma into the same position.

The difference in appearance between the empty and full anthers is very striking in dry weather.

Any one who knows the plants must have observed that they are very attractive to bees, and that they produce seeds in great abundance. CHRISTOPHER J. HAYDEN

Newspaper Science

THE general public cannot fail to acquire some very extraordinary as well as erroneous notions about many subjects relating to the progress and application of the different branches of Natural Science, if we are to judge from sundry scraps of information, daily communicated or reproduced for their instruction, in the columns of even the most influential newspapers. Amongst recent examples of this style style of information we might refer to the following:—

Geography.—Under the heading, "Oysters from South America," we find in the *Times* of May 16, the announcement that the steamer *Kaffraria* had last Sunday 'arrived at Hull from Norfolk, Virginia, having on board a cargo consisting of 500 or 600 tons of oysters, &c."

Geology.—The following is reproduced from the *Mechanics' Magazine* in the *Times* of May 16: —"*Per saltum.*—Nantwich in Cheshire has for some years past been gradually sinking, owing to the withdrawal of the lime from the salt lakes, which underlie the town," &c.

Chemistry.—In the *Times* of May 9 it is stated that "according to an analysis made by Prof. Zinno, the elements of the ashes that were thrown out from Mount Vesuvius are chlorine of soda, sulphate of lime, magnesia, allumen, iron, titanio, and silex."

Metallurgy.—The *Engineer* of April 12, in a paragraph on early iron making at Merthyr Tydvil, in South Wales, must rather astonish metallurgists by writing of "bones supplying sulphate of lime" in the process.

Architecture.—In a somewhat elaborate article on the new so-called Selenitic mortar, which in reality takes its name from the introduction of a little sulphate of lime, which when native forms the mineral called selenite in its manufacture, we are informed that "the name given to the improved mortar indicates to a certain extent the nature of the improvement; that it is in the direction of combining *selenious* acid with a base," &c. It would, indeed, be good tidings to chemists to find that selenious acid had become so cheap as to allow of its being used for such purposes; unfortunately, however, the last price lists inform us that selenium, from which it is made, still costs three shillings per drachm.

Although it has been said that it is not reasonable to expect scientific information from newspapers devoted to general topics, we still contend that we are entitled, when newspapers do make such statements, to demand that they shall at least be free from such gross blunders as those contained in the examples here cited, and to which many others might be added.

London, May 18 D. F.

The University of Freiberg

A LETTER signed "Undergraduate," in NATURE of May 9, confounds the School of Mines in Freiberg in Saxony with the University of Freiburg in Baden. The writer and others who wish to know where certain subjects are best taught in German universities will find much information in Ascherson's "Deutscher Universitäts-Kalender." This small book appears twice a year, giving the number of students and the names of lecturers and lectures offered each term in thirty-one universities of Germany, Switzerland, and the Baltic provinces of Russia.

Berlin, May 16 A. OPPENHEIM

Denudation of the Mendips

IN reply to the question of "Inquirer" in last week's number of NATURE, asking for explanation of a passage in my Address to the Geological Society, allow me to observe that geologists judge of the amount of denudation which hills formed by anticlinal axes, such as the Mendips and Ardennes, may have suffered, by prolonging across the range of hills the outcropping edges of the strata thrown up on the flanks of the axis, keeping each bed and each formation in its relative place. Thus, taking the thickness of the Somerset Coal measures, including the Millstone grit, to be on the north side of the Mendips about 9,000 feet, and of the Carboniferous limestone 1,500 feet; the whole of these, together with some upper part of the Old Red sandstone, forming together a mass of not less than 10,000 to 12,000 feet, have been removed from the area of the Mendips, the central axis of which is formed by strata of Old Red sandstone. In the case of the Ardennes, in addition to the Carboniferous strata, Devonian and Silurian strata are thrown up along the central axis at angles which prolonged form great arches, or rather a series of arches, over the hills; for here and there the intermediate synclinal curves bring in portions of the Coal Measures, which have thus been saved from denudation, while they show how much has been removed in the intermediate areas. The whole of the Coal measures, which are there rather thinner than in Somerset, the Lower Carboniferous series, which is much thicker than in England, together with the Devonian and part of the Silurian series, forming together a thickness probably of not less than 15,000 to 20,000 feet, are there removed from the central area.

It is, however, almost impossible to convey an exact notion of these great physical phenomena without illustrative sections and diagrams; and for these allow me to refer "Inquirer" to some papers in which such sections are given, and in which the subject, a very complicated one, is specially treated, viz., Professor Ramsay "On the Denudation of South Wales and the adjacent

counties of England" (Memoirs of the Geological Survey of Great Britain, vol. i. p. 297); Dupont's "Essai d'une Carte Géologique des Environs de Dinant" (Bulletin de l'Académie Royale de Bruxelles, vol. xx. pp. 9 and 10); Réunion Extraordinaire de la Société Géologique de France à Liège (Bulletin de la Société Géologique, 2 ser., vol. xx. p. 761); Elie de Beaumont's and Dufrenoy's Explication de la Carte Géologique de la France, vol. i. pp. 240-64; also to Lyell's Elementary Manual of Geology, article, "Denudation;" and to De la Béche's 'Geological Observer,'" p. 815.

Shoreham, Kent, May 18 JOSEPH PRESTWICH

VOLCANOES AND EARTHQUAKES

THE remarkable series of volcanic phenomena which have lately been exhibited at various parts of the earth's surface within so short a period of time, gives much matter for consideration, and must in due time afford us a rich harvest of facts with which to test the numerous theories which have been started to account for the occurrence of volcanic eruptions and of earthquakes. Even from our at present scanty information we have, I think, something to learn.

First in the series, so far as I am aware, was the very severe earthquake at Independence, Inyo County, California, which took place on Tuesday, March 26, commencing at 2 A.M., and lasting till 7 A.M., during which time "the earth was never for a moment perfectly quiet, and every few minutes heavy shocks, of a few seconds' duration, were occurring; in all there were more than fifty very heavy shocks." This place is only fourteen miles from the Black Rock, a volcano in the Sierra Nevada mountains, "the sides of which are covered with lava, and which is supposed to be an extinct volcano." It is stated that "during the time the shocks were most severe, flashes of light were seen to issue from the top of this mountain, and streams of fire ran down its sides."

The result of this earthquake is summed up in a few words as "the whole country turned topsy-turvy" (*Virginia City* (Nevada) *Enterprise*).

Then a few days afterwards came the terrific earthquake in Antioch, which commenced on April 3, and continued with greater or less severity, "in Aleppo, and as far east as Orfa, beyond the Euphrates," for more than a week, becoming very severe on April 10; here there appears to have been no actual volcanic phenomenon; but it appears from the letters of the Rev. W. Brown in the *Times*, that there exists in the immediate neighbourhood a mountain, "the peculiar conical form of which is very suggestive of an ancient volcano."

The latest African news tells us that "Several violent shocks of earthquake had occurred at Accra, on the Gold Coast, on April 14 and 15, causing considerable damage to the place." And as unwonted atmospheric disturbances have often been connected with volcanic phenomena, it may not be out of place to mention here the fearful hurricane which wrecked every vessel but one in the Harbour of Zanzibar on April 15.

And then on April 24 began the recent eruption of Vesuvius, which will be for ever memorable, not only on account of its magnitude and grandeur, but also, and still most so, by reason of the amazing intrepidity of the man, who, from a pure love of science, remained at his post, like the gatekeeper of Pompeii, throughout the whole of that terrible time, but happily was not, like that heroic soldier, buried in a shower of ashes; the world was spared the loss.

Now is there any connection between these phenomena exhibited in so distant parts of the earth's surface? One thing is certain, namely, that within the short space of a month all this has occurred, and one can hardly help thinking that somehow or other these volcanic countries must be connected underground; it has long been thought that Etna and Vesuvius are points on a volcanic area which passes north-west to the Eifel, Auvergne, and Iceland; has the neighbourhood of Antioch, with its unenviable notoriety for earthquakes, or the West African coast, anything to do with this area? But if so, what shall we say of the Sierra Nevada, why should its volcanoes be active at the same time? Why should the country there be "turned topsy-turvy" by earthquakes?

While pointing out these coincidences, we must not jump too hastily to conclusions from them; for on the one hand we are told that although the Antioch earthquake extended so far east, yet, to the north and south, even at a few miles' distance, nothing whatever was observed, and, on the other hand, that the Californian earthquake was of so superficial a character that "at Hot Springs, while severe shocks were felt on the surface, the men in the mines, 200 feet deep, felt nothing of them." Now the evidence goes to show that the latter earthquake was directly connected with the eruption of a volcano in the neighbourhood, so that, although the origin of the disturbance may be underground, possibly at a very considerable depth, the shocks are at a certain distance quite superficial, and moreover are transmitted in certain definite directions.

Taking all these facts together, they would rather seem to favour the conclusions that at any rate a great many, if not all, of the volcanic regions of the world are connected, and that they are not merely parts of the earth's surface which happen to be over isolated subterranean furnaces, but places where access to the exterior is more easy for the molten matter which lies underneath a great part, perhaps all, of the earth's crust. I must not be understood to be upholding the (shall I say exploded?) theory of the internal fluidity of the earth; I merely mean to point out that such coincidences in point of time ought to make one hesitate before rushing to the other extreme, and looking upon volcanoes as mere local eccentricities.

But it will be said, if there is any general commotion under even the volcanic area of Europe, why do not the extinct volcanoes of Auvergne break out again? Here is a difficulty which is not at all solved by the suggestion that at first occurs to one, that as the raising of the country has drained the enormous lakes, on the borders of which these volcanoes stood, there is no longer a supply of water to rouse them into action, for are there not lakes still in the Eifel, nay, are not those lovely lakes actually in the craters of extinct volcanoes?

Again, who has seen the wonderful natural harbour of Messina from the high ground above the town without believing it to be an extinct submerged crater? If there be still liquid rock below these craters, it may be that they are no longer the points of least resistance. And this is the probable explanation of their inactivity; for it must not be imagined that an eruption of Etna or of Vesuvius, or of any other volcano, necessarily means an ejection of ashes, lava, &c., from the crater, or from any crater; not at all, the weakest point in the vicinity gives way, and thus we have the numerous cones formed which surround every considerable volcano for some distance.

The mention of Auvergne leads me to make a few remarks on the disputed point, as to whether or not the volcanoes in that country have been in eruption within historic times, especially as I see that a correspondent in last week's NATURE has come to the conclusion originally drawn by "an eminent historian and antiquary, Sir Francis Palgrave," as long ago as 1844, and adopted by theological writers ever since, that because a bishop of Vienne established Rogation days on account of some alarming terrestrial phenomena which happened in his diocese, therefore the volcanoes of Auvergne were in action at the time. We have two documents which refer to this matter, a letter written by Sidonius Apollinaris (who lived in the very centre of the Chaine des

Puys, and on the border of a lake which was actually formed by the damming up of a stream by one of the most recent of the lava-currents) to Mamertus, Bishop of Vienne, in which he speaks of the earthquakes that had occurred in the neighbourhood of Vienne; of fire issuing from the earth and wild beasts taking refuge in cities; and the Rogation Homily of Alcimus Avitus, the successor to Mamertus, which mentions the same catastrophes.

Now in the first place Vienne is more than seventy miles in a direct line from the more recent Auvergne volcanoes; in the next, Sidonius himself makes no mention in his writings of any eruptions having taken place in his neighbourhood, although he wrote poems describing the beauty of the scenery: and lastly Auvergne is not mentioned by any ancient writer, neither by Cæsar, who encamped there and laid siege to Gergovia, a city situated on a table-land, with craters close at hand in almost every direction; nor by Pliny, who gives a list of all the then known volcanic countries, including some very out-of-the-way ones; nor by Strabo, nor by any of the poets, as a country where volcanoes were ever known to have been in action.

For these reasons, and because no volcano could have burst out near Vienne without leaving some traces of its existence, Dr. Daubeny concluded that the bishops of Gaul alluded to earthquakes; especially as "the underground thunder, the opening of fissures in the ground, the bursting out of flames and gases, the projection of water and of stones, the smell of sulphur, the alarm evinced by the animals of the spot and neighbourhood, the elevation or depression of the land, noticed by Sidonius and by Avitus in the passages referred to by Sir Francis Palgrave, are all reported as concomitants of the great earthquakes which have occurred in more recent times." Geologists have since accepted this conclusion as the correct one, in opposition to what I may call the theological position.

There was, however, a volcanic region which had not been visited by any English geologist, and which had not been described, viz., the basin of Montbrison, through which the Loire flows. Of this Mr. Scrope says in his work (2nd Ed., p. 28), "a further examination of this basin seems very desirable;" now as this district lies about half way in a direct line between the "Puys," about Clermont Ferrand and Vienne, it occurred to Dr. Daubeny that the disturbances spoken of as in the neighbourhood of Vienne, might have taken place around Montbrison, and accordingly in the autumn of 1866 he visited that locality, and I had the honour of accompanying him on the occasion. We examined carefully the volcanic hills of the neighbourhood, and could find no trace of recent volcanic eruptions; in his own description of this expedition published in the *Quarterly Journal of Science* for January 1867, and republished in his "Miscellanies" (vol. i. p. 74), just before his death, he says:—

"I am now prepared to say that, without pretending to have surveyed the entire district, I saw enough to convince me that no volcanic disturbance which had occurred within this area at so late a period as that alluded to could have escaped our notice, and that every indication of igneous action which presents itself throughout the country, bears marks of a much greater antiquity.

"Thus much, at least, I can venture to affirm, namely, that neither, craters, streams of lava, scoriæ, nor even cellular trap, are to be met with anywhere within the limits of this district. On the contrary, the only igneous rocks which came under our observation consisted of a compact basalt, containing nests of olivine, a material which could only have been elaborated by the aid of great pressure, and under a different configuration of the surface from that now existing."

The Doctor therefore reiterated his statement that "the lively picture drawn by Sidonius" should not "be regarded in any other light than as the offspring of a lively imagination, dwelling upon reports which had reached the author with respect to some fearful earthquake which may have occurred in the neighbourhood of Vienne."*

I will conclude by advising those who wish to study volcanic phenomena to go to Auvergne, they can do so at almost any time of the year, mid-winter, when it is far too cold for comfort, being the exception; they will there see results of volcanic action far more varied and instructive than at Vesuvius or even at Etna, and they will also be able to study the effects of denudation on a gigantic scale. Few geologists seem to appreciate the fact that within 24 hours of London is one of the largest, richest, and most beautiful of the volcanic countries in Europe.

W. H. CORFIELD

PHOTOGRAPHY AS AN AID TO SCIENCE

THE applications made of photography now-a-days are as various as they are numerous. Irrespective of the ordinary every-day uses to which the art is put in reproducing scenes and objects, or pandering to human vanity, there are, as we know, numberless ways in which it is constantly being employed as a faithful handmaiden to science. To the chemist, the surgeon, the engineer, and others, its aid is frequently of considerable importance, while to the astronomer and physicist the assistance it renders is at times indispensable. The accuracy and fidelity with which the pencil of light performs its functions, combined with the facility with which such reliable records are obtained, make photography indeed one of the greatest boons at the disposal of scientific men.

Let us take, for example, the solar records which are daily secured at the Kew Observatory. These photographs of the sun's disc, taken whenever practicable at a certain fixed period in the day, are often of considerable value, and form illustrations, as it were, of other scientific observations made at the same time. A series of prints of this kind, secured day after day, afford, in truth, a most interesting and instructive lesson to the student of astronomy, for the characteristics exhibited by the various photographs may serve as a corroboration, or otherwise, of scientific theories based upon other data and results. The nature and luminosity of the markings, or spots, upon the disc are rendered with unerring fidelity, and the way in which these are continually modified in shape and intensity, as likewise the rapidity with which they are seen to travel across from the east to west limb of the sun, to reappear again some twelve days afterwards upon the eastern edge, is all clearly and distinctly shown.

Again, another interesting application of photography to astronomic purposes is to be found in the reproduction of the stars as recently undertaken by Prof. Rutherford. In this instance the objects to be secured are so minute that special precautions are necessary in depicting them upon the sensitive film, so that their impressions may be distinguishable from accidental specks in the collodion plate. To prevent any such chance of mistake, Prof. Rutherford secures a double image of each luminary, the moving telescope to which the miniature camera is attached being halted for a short time (half a minute) between a first and second exposure of the plate, so that each star is represented by a double speck, so to speak, upon the negative, and is clearly to be distinguished therefore, from any accidental defect in the film; moreover, by stopping the telescope again after the period necessary for the second exposure, the professor is enabled to demonstrate the direction in which the stars are moving, for the brightest of them produce a tiny streak of light during the time that the camera remains perfectly still. A map or plan of the heavens is in this

* Those who wish for further information will find the whole subject discussed in Dr. Daubeny's classical work on Volcanoes, and in his papers in the *Quarterly Journal of Science* for April 1866 and January 1867.

way secured, very slight and delicate in its nature, it is true, but yet one upon which implicit reliance can be placed when undertaking astronomical measurements. To those more particularly interested in operations of this kind, we may mention that a total exposure of six minutes sufficed for the depiction of these heavenly bodies in the camera.

Turning to another branch of the subject—micro-photography—we find the camera used for several purposes as important almost as those to which we have just referred. In the study of medicine, for instance, and the many sections of Natural History, photography lends a helping hand, so firm and true that we are at once guided to our destination. The large, clearly-defined diagrams of microscopic objects and medical preparations, which we are wont to see at many schools and colleges, cannot be prized too highly, forming as they do the best and most reliable proofs in support of facts and data, and being indeed of value alike to the professor as the student. And perhaps while treating on this particular subject, we may be allowed to refer also to the use made of the micro-camera during the siege of Paris for conveying news from and to that city. We have all heard how batches of private letters and whole sheets of newspapers have been reduced by means of photography to within the most insignificant limits, and produced upon a transparent pellicle, of which a pigeon might without inconvenience carry several under its tail, and how these precious films, on arrival at their destination, were forthwith placed in an enlarging apparatus or under a microscope, to be amplified to their original dimensions. Paris, it is said, contained upwards of a thousand pigeons qualified to act as messengers, and when it is asserted that on one occasion one of these birds arrived at Tours with several thousands of private messages and despatches, we ought by no means to be surprised that the communications between the French metropolis and the provinces were so numerous and frequent.

In the chemical, physical, and meteorological sciences, and even in that of war, photography aids in many ways, and thus helps to the advancement and progress of our knowledge of these matters. But the art, or art-science, as we may call it, has in several instances done something more than render yeoman's service to higher attainments; it has also been the means of discovering phenomena which could by no other means have been ascertained. In illustration of this may be mentioned the recent researches of Dr. Ozanam, undertaken for the purpose of defining the character of the pulsations of the heart; an investigation which has brought to light facts of considerable physiological importance. The instrument used by Dr. Ozanam was a thin India-rubber reservoir of mercury, having a glass tube attached, in which the quicksilver mounted to a certain height; the reservoir, on being placed in the vicinity of the patient's heart, was influenced by the beating of the latter, and the rise and fall of the mercury in the tube was thus made to indicate the ebb and flow of the blood, precisely in the same manner as a barometer registers the variations of the atmosphere. Behind the tube was arranged, by means of clockwork, a moveable strip of sensitive paper, or other suitable material, and this, as it ran along, was impressed by light, and received, in the form of an undulating line, a register of the fluctuations of the mercury column. The sensitive film passed along at the uniform rate of a centimetre per second, so that, presuming there to be one pulsation in that period of time, the wavy line representing a single beat would occupy the space of one centimetre. Of course, by enlarging the result to ten or twenty diameters, it was then, as may be supposed, easy to see what had taken place during the hundredth or thousandth part of a second, or beat, and the knowledge thus acquired, Dr. Ozanam believes, will be highly useful in preparing the diagnosis of a patient. One fact, of itself very important, has already been discovered by the aid of this ingenious instrument, viz., that not only as Dr. Maurey had before asserted, there exists dicrotism, or a double beat, in the normal pulse, but that the pulsation is even triple and quadruple in its action. The photographic line showed indeed that the column of mercury (representing of course, the blood in the arteries) bounded with one leap to the top of the scale and then descended again to its original level by three or four successive falls. Four descriptions of dicrotism have in this way been proved to exist, the fall of the pulse sometimes taking place in successive horizontal lines and sometimes in ascendant lines, the column reascending two or three times before falling altogether.

Another instance of scientific discovery by aid of photography is afforded in the observations of the spectrum by means of the camera. In Rutherford's picture of the solar spectrum obtained in this manner, there are many portions and lines shown (the ultra-violet for instance) which, while imperceptible to the retina of the eye, impress themselves very distinctly upon the sensitive film; and thus the presence of phenomena is proved of which but little was previously known. Of course the eye again descries certain lines, the yellow ones, which are without action upon the negative plate, and are not, therefore, recorded in the photograph, and thus it is only by carefully noting the results of both methods of observation that a true reproduction of the spectrum is obtainable. As a fact, we may mention, that single lines which are but faintly rendered in the Angström and Kirchhoff tables have been recorded by photography as well-marked double lines, while in some instances actually Rutherford shows indications by means of the camera of which there appears no vestige whatever in the records of other scientific men. In certain spectroscopic observations therefore, where special reliance is required to be placed upon the results, not only must an ocular observation be made, but the photographer's evidence must also be taken before any conclusions can be drawn from the aspect of the spectrum.

And before concluding we must not forget to refer to a still more recent instance in which photography has befriended the scientific investigator; we allude to the successful, although perhaps somewhat imperfect attempt which has been made by Prof. Young, to photograph the protuberances of the sun in ordinary daylight. A distinct reproduction of some of the double-headed prominences on the sun's limb has thus been obtained by the Professor; and although as a picture or mathematical record the impression may be of little value, still there is every reason to believe, now that the possibility of the operation is known, that with better and more suitable apparatus an exceedingly valuable and reliable record may be secured. Prof. Young employed for the purpose a spectroscope containing seven prisms, fitted to a telescope of $6\frac{1}{2}$ inch apperture after the eyepiece of the same had been removed; the miniature camera, with the sensitive plate, was attached to the end of the spectroscope, the eyepiece of which acted in the capacity of a photographic lens, and projected the image on the collodion film. The exposure was necessarily a long one, amounting to three minutes and a half, and for this reason, as likewise on account of the unsteadiness of the air and the mal-adjustment of the polar axis of the equatorial, causing the image to shift its place slightly, the details of the image were somewhat blurred and destroyed. Moreover the eyepiece of the spectroscope was unsuitable for photographic purposes, and only in the centre yielded a true reproduction of the lines free from any distortion. A larger telescope will be required to secure a more defined image, and then, if more strict attention is paid to the clock-work arrangements and to the chemical manipulations, we may anticipate that a really valuable and important result will be obtained by this novel mode of observation.

H. BADEN PRITCHARD

AN EXPERIMENT TO ILLUSTRATE THE INDUCTION ON ITSELF OF AN ELECTRIC CURRENT

IT is well known that the sudden development of a current in a conductor is opposed by an influence analogous to the *inertia* of ordinary matter. A powerful movement of electricity cannot be suddenly produced; neither can it be suddenly stopped. One consequence is that a periodic interruption of a circuit in which a constant electromotive force acts is sufficient, when the self-induction is great, to stop all sensible current, even although the interruptions themselves may be of very short duration. Before any copious flow can be produced the circuit is broken, and the work has to be begun over again. Whether in any particular case the influence of self-induction is paramount, or not, will depend also on the *resistance* of the circuit, and on the rapidity of the intermittence. The magnitudes which really come into direct comparison are the interval between the breaks, and the time which would elapse while a current generated in the circuit, and then left to itself, falls to a specific fraction (such as one-half) of its original magnitude. In ordinary cases the duration of transient currents is but a small part of a second of time, so that, in order to bring out the effects of self-induction, the breaks must recur with considerable rapidity.

There is, however, one remarkable exception to the general rule, which occurs when, alongside of the principal coil to which the sluggishness is due, there exists an independent course along which the electricity can circulate. For instance, suppose that a coil with two wires, such as is often used for electro-magnets, is so arranged that one wire is included in the principal circuit, while the ends of the others are joined. The effect of the second circuit is then to neutralise the self-induction of the first, and so to increase largely the current that passes through it. Let us trace the progress of the phenomenon; supposing that the first circuit has been closed for a sufficient time to allow of the development of the full current which can be excited by the actual electromotive force.

The moment the rupture is complete, the current in the first wire must stop, but another of the same magnitude and direction is at once developed in the neighbouring circuit. In fact, in virtue of its *inertia*, the electrical motion tends to continue with as little change as possible, a result which is attained in great degree by the formation of the second current to fill the place of the first. In a short time the induced current would diminish and become insensible under the operation of resistance (analogous to ordinary friction); but we are supposing that before this takes place to any considerable extent the contact is renewed, and the electromotive force again begins, in the first circuit, to push the electricity on. It is now that the peculiarity of the arrangement manifests itself. The current instantly transfers itself back again to the first circuit, which thus, without any delay, has the advantage of the full current which the electromotive force can sustain. If it had not been for the second circuit and its current, the development in the first would only have been gradual, and by supposition so slow that it would be checked by another interruption before any considerable progress could be made. In short, the self-induction of the principal circuit is virtually destroyed.*

In my experiment the principal circuit consisted of a Smee cell and one wire of a coil belonging to a large electro-magnet, and which I may call A. The interrupter was a tuning-fork, arranged after Helmholtz, and set into regular vibrations of about 128 per second by an independent current and battery. The fork itself was forged by the village blacksmith, and the whole affair was home-made. Across one prong was placed a sort of rider of copper wire, dipping on either side into a mercury cup, and so arranged that during the vibration its ends should enter and leave the mercury, thereby establishing and interrupting the continuity of the circuit. The current was measured by means of a short wire galvanometer whose electrodes were connected with two neighbouring points of the circuit in such a manner that a small but constant proportion of the entire current passed through the instrument. The second wire of the coil. A_2, which is similar to the first and *put on with it*, formed the second circuit, when its ends were joined by a short wire. In order to increase at pleasure the effects of induction, iron wires or rods of about a quarter of an inch in diameter were provided, whose insertion in the coil materially increased the decisiveness of the result.

In the first place, the deflection produced on the galvanometer when the circuit was permanently completed was 58°, which fell to 39° when the interrupter was at work, the circuit of A_2 being open, and without iron. On closing A_2 the deflection rose to 46°. A_2 was again opened, and one iron wire introduced, which gave 30°. Two wires gave 25°, while the introduction of thirty reduced the deflection to 12°. Again closing A_2, the reading was 43°, raised to 44° only by the removal of the iron. It was clear that the second circuit almost secured the first from the influence of induction, which otherwise greatly reduced the electrical circulation. I may add that the arrangement was very efficient, the galvanometer needle remaining perfectly steady, so that the readings could be taken with ease and accuracy.

Another experiment made at the same time (about two years ago) may be noticed, if only for its contrast with the preceding. The coil A, being removed from the main circuit, was included in the branch with the galvanometer, as shown in the figure. Here neither the insertion of

iron nor the closing of A_2 made any difference; the circuit containing the coil remaining always closed, whatever might be the condition of the other. In such circumstances the average current indicated by the galvanometer is independent of the self-induction of the coil, varying only with the resistance in the branch, and with the *average* difference of potential at the points of derivation.

J. W. STRUTT

* Mathematicians familiar with the theory of electricity will follow this by putting the three induction co-efficients (in Maxwell's notation, L, M, N) equal, and the resistance of the second circuit, S, equal to zero.

SOME REMARKS ON THE HABITS OF SOME CEYLON ANIMALS, AND NOTES ON METHODS FOR KEEPING THEM ALIVE IN CONFINEMENT

AFTER my duties as member of the Eclipse Expedition were over, I spent some time in Ceylon collecting natural history specimens for the Oxford Museum. Besides preserving a large series of animals in solutions, I obtained through the kindness of my friend, Mr. G. H. K. Thwaites, F.R.S , of Peradeniya, whose kind hospitality I enjoyed, and to whom I am indebted for nearly all my best specimens and information concerning them, various living examples of the Ceylon fauna, and I kept them with more or less success in confinement. Some notes

as to my experiences with regard to them may be of interest to the readers of NATURE.

Passerita mycterizans.—A brilliant emerald green tree snake, with horizontal pupil. I obtained a fine specimen about 4½ ft. long. I put him in a small wooden box with wire-gauze cover. As usual with this species, he would not feed, but drank frequently with great eagerness. Snakes often die in confinement for want of water. In the case of tropical snakes, it should not be forgotten that the water must be warmed as soon as colder latitudes are reached. This snake is now in the Regent's Park Zoological Gardens, and has now been two months without food. The keeper tells me that a specimen formerly in the Gardens lived six months without eating.*

Lyriocephalus scutatus.—These lizards live in large numbers in the Royal Botanic Gardens, Peradeniya, frequenting the moist shady banks of the Mahawillaganga, which bounds the Gardens in one direction. The animals sit all day on tree trunks, with their head uppermost. They can run very fast, but are easily caught, as is the case with most lizards, with a slip noose of palm fibre. They allow the noose to be put over their heads with the greatest ease. When first caught they are very fierce, and display their array of sharp teeth and bright scarlet mouths whenever a finger is moved near them, and they bite hard whenever they get a chance, holding like bull-dogs, as I often experienced to my cost when feeding them. I could not get them to feed themselves either whilst in Ceylon or on the voyage home. I therefore fed them by hand, opening their mouths forcibly by pulling on the pouch-skin and pushing worms down their throats. After a time they chewed and swallowed the worms readily on their being put in their mouths. I also poured water down their throats. I kept a stock of worms alive at the bottom of the cage in moist earth. Kelaart, in his Nat. Hist. of Ceylon, says that Lyriocephalus takes boiled rice freely in confinement; and Dr. Günther, "Indian Reports," p. 129, quotes him to that effect. I think this must be an entirely erroneous statement. I forced rice down the animals' throats, but they never seemed to relish it, and they never touched it of themselves whilst under my care, nor have they done so since they have been in the Regent's Park Gardens. The lizards are remarkable for their curious lyre-shaped heads, and the large knobs on the ends of the snouts of the adults. In young specimens the knob is very little developed. It is present in both sexes. The lizards change colour with great rapidity when excited, even whilst held in the hand. They were brought home in a tall wooden cage, by the advice of Mr. Thwaites so arranged that they could rest in their usual vertical position on some rough bark nailed on to the sides of the cage for the purpose. They clung on to these supports and the perforated zinc front during all the voyage home, and in their den in the reptile house in the Gardens they are always to be seen clinging to the branches head uppermost. The cage was kept on the voyage from Alexandria to Southampton in the engine-room of the P. and O. steamship *Mooltan*, as was also the box with the tree snake, and both were taken up to town from thence wrapped in a double blanket. Four of the lizards are now alive in the Regent's Park Gardens. They are still fed by hand, but one has been seen by the keeper to help himself to worms. Some time ago an attempt was made by Mr. Houldsworth to bring Lyriocephali home alive, but his specimens unluckily died in the Channel. Perhaps they were not hand-fed.

The ground in Ceylon swarms with burrowing reptiles of various kinds, and Mr. Thwaites's coolies used to dig me up as many as twenty in an afternoon. They all came from the moist river bank. Most abundant in the various lots I received was always *Nessia monodactyla*, a lizard which, having taken to underground habits, has become snake-like, and retains the merest rudiments of both its limbs. I kept all my underground reptiles in damp moss in joints of the gigantic bamboo. The *Nessias* move with great agility through the moss, and lived well in confinement. I hardly ever saw one in which the tail was not a reproduction.

Rhinophis Bythii.—These were not half so nimble as the *Nessias*, and seemed rather more delicate.

Typhlops braminus.—These small blind-worm-like snakes were not so abundant as the *Rhinophidæ* or *Nessias*, but there were generally one or two in each batch. They are very active, escape through the smallest crack, and are with difficulty retained in the hand. I kept the *Nessias*, *Rhinophidæ*, and *Typhlopidæ* together in a bamboo. I gave them earth-worms. The worms disappeared, but also did the *Typhlopidæ*. These could not have escaped; but were probably eaten by the *Rhinophidæ*.

Cæcilians.—Epicrium glutinosum.—I had only four specimens brought me of *Cæcilia*. They came from the same bank as the *Nessias*, &c. They move along the ground with a slow helpless wriggling motion, feeling their way with their remarkable exsertile labial tentacles. These tentacles are in constant motion, being alternately protruded and retracted. They are evidently the animals great stand-by in the special-sense way, and probably contain interesting terminal nervous organs. The Cæcilians have a certain amount of prehensile power in their tails. When placed in water they are very active, moving like eels, and seeming to enjoy themselves thoroughly. I kept them in moss in a bamboo, and put worms with them, which disappeared in no small quantities.

Mygale marmorata.—This spider, a full-sized one, ate clean up five large cockroaches in the first two nights I had it. A day later it cast up a large pellet, composed of the chitinous skins of its victims, just as a rapacious bird casts up feather pellets. It spun a small quantity of irregular web against the side of its cage. As far as I could observe, the spider did not feed again in the three weeks during which I kept it alive.

Scorpion hubrŏstonos.—These large black scorpions I could not get to feed at all, though I tried them with insects and raw meat.

Land Planarians.—Bipalium Diana, *B. Proserpina*, *B. Phœbe*, and *Rhynchodemus Nietneri.*—I obtained numbers of specimens of these huge Planarians, some as much as eight inches long. I tried several times to keep them alive amongst moist leaves, but unfortunately failed. They never lived longer than four or five days, then appeared to deliquesce into a slimy mass of corruption.* The slime of these Planarians is so tough that they can suspend themselves by a thread formed of it, and I have several times had them lower themselves thus from my hand to a table by means of a thread six or seven inches long. I have only seen *Bipalium Diana* and *Proserpina* do this, not *Rhynchodemus*. The cellar slug, *Limax agrestis*, uses a mucous thread for suspension in a similar manner (Binney's "Terrestrial and Air-breathing Molluscs of the United States," vol. ii. p. 39). When in motion, the Bipaliums throw out a series of short tentacular-like papillæ from the front edge of their semicircular anterior extremity. I had all the animals I have mentioned, except the Planarians, alive as far as Suez, but unfortunately they were all killed by the intense cold of the night journey across the desert to Alexandria, except the Lyriocephali and Passeritia, which I took in the carriage with me and kept warm. The train was so crowded that I was obliged to put the rest in the van. I especially grieved over the loss of the Cæcilians; they were especially well and healthy, and I feel certain I should have got them home alive had it not been for this mishap. I had hoped to be able to get them to breed, and to watch their development.

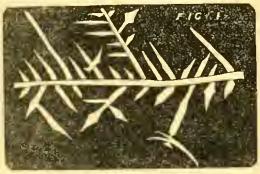
H. N. MOSELEY

* Since the above was written this snake has not only swallowed a young bird, but has also attempted to swallow another snake of a different species confined in the same cage.

* Mr. Darwin had much better success with the South American Land Planarians.—"Darwin's Journal of Researches," 1860 Edition, p. 27.

ON THE CRYSTALLISATION OF SILVER, GOLD, AND OTHER METALS *

THERE are few chemical experiments so well known as the growth of the "lead tree" a specimen of which is on the table, together with a "silver tree" that is said to have been made by the late Professor Faraday. These carry our minds back to the time of the alchemists, who called the first "arbor Saturni," and the second "arbor Dianæ;" and they may be looked upon as the types of a large number of phenomena, in which the salt of one metal in solution is decomposed by some other metal. My assistant, Mr. Tribe, and myself have been lately ex-



amining these replacements, the metallic crystals which are thus produced, and the forces that act through the liquid.

Our more special attention has been given to the mutual action of copper and nitrate of silver. If these two substances be brought into contact by the intervention of water, there grow upon the red metal what may be well

called "trees," and though the analogy between crystals and plants is a very superficial one, yet the resemblances of external form are striking enough, and a nomenclature drawn from the garden seems the most expressive.

It is very beautiful to watch the growth of these silver crystals round a piece of copper under the microscope; a blue glass underneath adds to the effect, and they are

best seen when they reflect a strong light thrown upon them. They may also be thrown upon a screen as opaque objects, but the beauty and lustre of their surface is in this way lost.

The crystals of silver thus produced differ both in colour and form, according to the strength of the solution. If it be very weak, say one per cent., the copper is fringed with black bushes of the metal, which, in growing, change their colour to white without any alteration of crystalline form that can be detected by a powerful microscope. A stronger solution gives white crystals from the commencement, which frequently assume the appearance of fern-leaves; while the growth from a still stronger liquid reminds us rather of a furze bush. If the nitrate of silver amount to 15 per cent., or thereabouts, there occurs a steady advance of brilliantly white moss; and if the solution be saturated, or nearly so, say 40 per cent., this moss is very sturdy, often ending in solid crystalline knobs, or stretching out into the liquid as an arborescent fringe.

In all these cases, however, when the solution in front of the growing crystals has been somewhat exhausted, certain prominent or well-circumstanced crystals seem to

monopolise the power, and to push forward through the remaining portions of the liquid. This gives rise to beautiful branches which assume a variety of graceful forms, which it is hopeless to attempt to pourtray by diagrams, but of which the subjoined figures give some of the more characteristic outlines greatly magnified. The weak solutions produce feathery crystals somewhat as in

Fig. 1, consisting of a straight central stem from which grow on either side crystalline rays that terminate in a sharp point, and frequently become themselves the centre stems of a similar crystalline structure. In the outlying growth of a moderately strong solution the apparent regularity of the crystalline form is lost; the main stem is built up of a confused mass of hexagonal plates, while

the side branches are an agglomeration of minute pointed crystals turning in every direction, and producing such jagged outlines as are drawn in Fig. 2. In stronger solutions still the branches lose every appearance of straightness, and they are built up of hexagonal plates so studded with crystalline specks that the whole has the rounded appearance depicted in Fig. 3. The arborescent crystals that succeed the fringes from a saturated solution, are smaller in their foliage than the last, and end in little spherical or botryoidal knobs.

* Lecture delivered at the Royal Institution of Great Britain, February 16, 1872, by John Hall Gladstone, F.R.S.

Beside these various forms, there occur all kinds of crystalline combinations, as, for instance, the spray sketched in Fig. 4, where the rough branches have terminated each in a large hexagonal plate, and the flowing past of a weakened solution has afterwards caused the growth of delicate fern-leaves. Often, too, a large expansion will take place in every direction, though joined to the parent stem by an almost invisible thread; or from the point of a long crystal there will branch out to right and left crescent-shaped structures, a process the commencement of which is seen in one of the side rays of Fig. 1. The last traces of silver in the liquid will frequently give rise to delicate crystalline filaments wandering over the surface of the glass, as in Fig. 5.

If a piece of zinc be placed in a solution of neutral terchloride of gold, containing 9 per cent. of salt, there is an immediate outgrowth of black gold, which speedily changes to an advancing mass of yellow or perhaps lilac metal in lichen-like forms, from which proceed beautiful fringes of yellow or black, ending generally in such

FIG 7

arborescent forms as are represented in Fig. 7. As these branches push into the yellow liquid, it becomes colourless even in advance of their points, and it frequently happens that yellow crystals of some salt shoot out in front of the crystallising metal, which follows them and builds up its advancing fronds at their expense. This is shown in the figure. The gold will generally shoot its yellow branches rapidly round the margin of the drop. Such a running branch has been seen to stop on touching at one point a loose piece of gold, which immediately in its turn became active, and commenced to sprout on its farther side. Copper salts give round nodules, which have no crystalline appearance when deposited from moderately weak solutions, but a very strong solution of the chloride—about 40 per cent.—yields with zinc first a black thick growth, then arborescent fringes of red metal, terminating in crystals of very appreciable size.

The fringes referred to in the case of these three metals are still more characteristically developed by bismuth. When a solution of terchloride of bismuth acts on zinc,

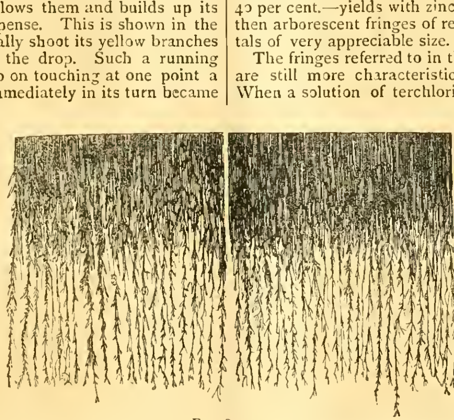


FIG. 8

there is an immediate outgrowth of black fringes, such as Fig. 8, where they are seen on an illuminated field. These, as they advance, become more and more arborescent, and as the crystalline character develops itself more they change from black to grey. Sometimes bismuth presents itself in botryoidal masses, but the tendency to form these fringes is very strong.

Chloride of antimony with zinc also gives these black fringes. Lead salts yield crystals resembling those of silver; but leaves of irregular hexagonal plates prevail, and often grow to a large size. A solution of acetate of thallium, containing 20 per cent. of salt, quickly gives a beautiful forest of thorny crystals. Sulphate of cadmium gives rise to a small leaf-like growth on zinc; but a strong solution of chloride produces an appearance of sticks covered with small spines or knobs. The new metal indium is thrown down upon zinc in the form of thick white crystals. The deposition is promoted by touching the zinc with a piece of iron.

Tin gives beautiful results. If zinc be placed in a solu-

tion of stannous chloride, it is quickly surrounded with an outgrowth of prolonged octohedra, and as these advance into the liquid it is easy to observe that the additions of new metal commence at the apex, and that the wave of chemical change proceeds down the lateral edge, occupying some seconds of time in depositing the new layer of material. Frequently, also, there is a luxuriant growth of large flat leaflets, or of symmetrical structures resembling fern-leaves, but with the fronds arranged at right angles, or combinations of these with octohedra, as shown in Fig. 6. These fern-leaves often begin of a dull grey colour; but, as they advance, suddenly change to a brilliant white.

The particular form of these crystalline growths depends, therefore, primarily, on the specific character of the metal; but this is greatly modified by the strength of the solution.

The forms assumed by native metals resemble those produced by this process of substitution. In some cases, indeed, it seems almost certain that the deposition of these minerals was effected in the same way, as, for instance, the silver which occurs sometimes in tufts, sometimes in large crystals, on the native copper of the Lake Superior district. Gold is frequently found in cubes more or less rolled, but the leaf gold from Transylvania bears a striking likeness to the crystals that form in our laboratory experiments. Silver is often found native as twisted hairs or wires of metal—a form that never occurs in the decomposition of its nitrate by copper, but which can be artificially produced in another way.

There has been noticed a singular tendency in old silver ornaments and coins to become crystalline and friable. Here is an ancient fibula from the island of Cyprus, supposed to be at least 1,500 years old, which, through the greater portion of its substance, presents a fracture something like that of cast-iron, and its specific gravity has been reduced in round numbers from 10 to 9. It contains a little copper. This property of certain metals or their alloys to change in condition and volume, is worthy the attention of those whose duty it is to make our standards. Experiments should be instituted for the purpose of learning what metals or combinations of metals are least subject to this secular change.

These metallic crystals are Nature's first attempt at building. This material is the simplest possible—in fact, what chemists look upon as elementary. But how is the building carried on? What are the tools employed? Where are the bearers of burdens that bring the prepared pieces and lay them together according to the plan of the Great Architect? We must try to imagine what is taking place in the transparent solution. The silver, of course, existed at first in combination with the nitric element, and for every particle of silver deposited on the growing tree, an equivalent particle of copper is dissolved from the surface of the plate. The nitric element never ceases to be in combination with a metal, but is transferred from the one metal to the other. On the "Polarisation Theory," the positive and negative elements of the salt constantly change places and enter into fresh combinations, one consequence of which would be a gradual passage of the nitric element from the growing silver to the copper plate. This actually takes place, and there is a diminution of the salt at the ends of the silver branches, giving rise to an upward current, and a condensation of nitrate of copper against the copper plate, which gives rise to a strong downward current. These two currents are seen in every reaction of this nature. In the case of silver and copper, however, it has been proved that the crowding of the salt towards the copper plate is more rapid than would follow from the usual polarisation theory. The instrument employed for determining this point was a divided cell in which two plates, one of silver and the other of copper, connected together by a wire, are immersed each in a solution of its own nitrate, contained in each division of the cell, and separated from one another merely by parchment paper. The crystals of silver deposited on the silver plate in this experiment are very brilliant.

There are other indications of the liquid being put into a special condition by the presence of the two metals which touch one another. Thus zinc alone is incapable of decomposing pure water; but if copper or platinum be deposited on the zinc in such a manner that the water can have free access to the junction of the two metals, a decomposition is effected; oxide of zinc is formed, and hydrogen gas is evolved. At the ordinary temperature the bubbles of gas rise slowly through the liquid, but if the whole be placed in a flask and heated pure hydrogen is given off in large quantity. We have also found that iron or lead similarly brought into intimate union with a more electro-negative metal, and well washed, will decompose pure water.

As might be expected, the action of magnesium on water may be greatly enhanced by this method; and a pretty and instructive experiment may be made by placing a coil of magnesium in pure water at the ordinary temperature, when there will be scarcely any effect visible, and then adding a solution of sulphate of copper. The magnesium is instantly covered with a growth of the other metal, and at the same time the liquid seems to boil with the rapid evolution of hydrogen bubbles from the decomposed water.

When, however, the force of the two metals in contact has to traverse a layer of water, the resistance offered by the fluid prevents its decomposition. This must also be an important element in the decomposition of a metallic salt dissolved in water, and in fact we have found that the addition of some neutral salt, such as nitrate of potassium, increases the action—apparently by diminishing the resistance of the liquid. If, too, we increase the quantity of the dissolved metallic salt, we get more than a proportional increase of deposited metal. Thus, in an experiment made with the different strengths of nitrate of silver on the table, the following results were obtained in ten minutes, all the circumstances being the same except the strength of the solution:—

1 per cent.	solution	dissolved	·025	grm. copper.
2 ,,	,,	,,	·078	,,
4 ,,	,,	,,	·224	,,

In fact it has been found that in solutions not exceeding 5 per cent., twice the amount of nitrate of silver dissolved in water gives three times the amount of chemical action; and this is true with other metals also in weak solution. It may be that this is not the precise expression of a physical law, but it agrees at least very closely with the results of experiment.

The power arising from this action of two metals on a binary liquid may be carried to a distance and produce similar decompositions there. This is ordinary electrolysis. Metals have often been crystallised from their solutions in this way, and Mr. Braham has made excellent preparations of crystalline silver, gold, copper, tin, platinum, &c., by using poles of the same metal as that intended to be deposited upon them. The forms thus obtained are precisely analogous to those produced by the simple immersion of one metal into the soluble salt of another, and illustrate still further the essential unity of the force that originates the two classes of phenomena.

NOTES

THE speech of the Prime Minister at the meeting held last week in support of the fund to pay off the debt at King's College was a striking comment on some recent utterances of members of the Government to the effect that Science is well able to support itself, and needs no assistance from the State. The claims of this fund on public assistance were earnestly and

eloquently urged on the ground that King's College was an institution founded to promote the union between Science and Religion, and therefore the happiness of mankind. In the course of the meeting it was mentioned that the works connected with the Thames Embankment have entirely destroyed the dining-hall of the College, entailing a loss of 1,400*l.* or 1,500*l.*, for which no legal redress can be obtained; and this although noble dukes receive compensation to the extent of thousands of pounds for the injury inflicted on the privacy of their gardens by the same works.

ON the occasion of the annual conferring of degrees by the University of London on the 15th inst., Mr. Lowe, who is a member of the Senate of the University and its representative in Parliament, expressed an opinion in favour of making Greek an optional subject at the Matriculation Examination, to be substituted either by an additional modern language, or by some branch of natural or physical science. The proposed change has now been before the body of graduates for the last two years, but has not yet received the sanction of Convocation. At the last meeting, on the 14th inst., the subject was referred back to the Annual Committee of Convocation for further consideration. In the course of the same speech, Mr. Lowe urged benefactors of education to leave money for the endowment of scholarships at the University, rather than of professorial chairs, on the ground that the pay of lecturers ought to be in proportion to the amount of instruction they give, *i.e.* to the number of their pupils. Mr. Lowe appears, however, to forget that quality, as well as quantity, is required in teaching, and that this quality can only be secured by original work, to devote himself to which the professor must be to a certain extent independent of the emoluments derived from actual teaching.

THE special correspondent of the *Daily News*, writing from Zanzibar under date of April 19, states that no letters had been received there from either Dr. Livingstone or Mr. Stanley up to that date, and that war was still going on in Unyanyembe between the Arabs and the natives. The terrible hurricane of the 13th had wrecked every vessel in the harbour of Zanzibar except the *Abydos*; the harbour was then one mass of wreck, and European residents expect that a famine may be the result, the cocoa-nut and clove-trees, the chief products of the island, having been almost entirely destroyed, and that trade will be brought to a standstill for some time. Mr. Horace Waller forwards to the *Times* a letter just received from Mr. Oswell Livingstone, in which he speaks of the expedition being detained in Zanzibar by the hurricane up to April 20; and Prof. Corfield sends one to the same journal from Dr. James Christie, physician to the Sultan of Zanzibar, who says that he believes Dr. Livingstone is alive and well, and that Mr. Stanley has relieved him at Ujiji, and that he would not be surprised to meet them both in Zanzibar any day.

WE are very glad to be able to announce that the United States Senate has unanimously passed a bill, appropriating 50,000 dols. to meet the expenses of the observations upon the transit of Venus in 1874, on the part of the National Observatory in Washington. The bill has been introduced into the Lower House, and will doubtless soon become a law.

PROF. PALMIERI of Naples has received an address, signed by seventy citizens of Rome, expressing their admiration of his character and conduct, and congratulating him on the success of his efforts to save numerous victims from destruction in the late terrible eruption of Vesuvius. A communication from Rome states that he is to be nominated a senator of the Kingdom of Italy.

THE Royal Danish Society of Copenhagen offers the following prizes for competition during the ensuing year:—For a description of the spectra of the planets Venus, Mars, Jupiter, Saturn, and Uranus, which shall determine the question relating to the position and special nature of the principal lines, accompanied by a critical comparison of the results previously obtained by Huggins, Secchi, Vogel, and, as respects Jupiter, by Le Sueur, of Melbourne—the gold medal of the Society, together with a sum of money of fifty Danish ducats (450 frs.). For a thorough research into the organic reproduction of one of the groups of setiferous Annelidæ, the Naididæ, Scyllidæ, or Serpulidæ, especially with relation to the question whether the same individuals are both gemmiferous and sexual, or whether the sexual and organic modes of reproduction are strictly separated in different individuals and generations, accompanied by the necessary drawings—the gold medal of the Society. The essays may be written in Latin, French, English, German, Swedish, or Danish; and must be addressed before the end of October 1873 to the secretary of the society, M. J. J. S. Steenstrup.

SOME little time ago we noticed in our columns an effort that was being made to raise a memorial to the late Sir R. Rede, the founder of the Rede Lecture at Cambridge, and we are glad to be able to state that in consequence several fresh subscribers have added their names to the list, so that the fund now amounts to 80*l.*, which is exactly one half of the sum required for the window that it is proposed to fill with stained glass in the church where the remains of this far-seeing friend to knowledge rest. The Rede Lecture is to be delivered in the Senate House, Cambridge, on Friday, 24th inst., by Mr. Edward H. Freeman, D.C.L., on the Unity of History, and it is hoped that members of the University, as well as others interested in the promotion of science, will contribute towards the completion of the memorial of which a partial commencement has been made by inserting a portion of the glass. The Rev. Professor Selwyn, D.D., has kindly consented to receive subscriptions at Mortlock's Bank, Cambridge, "Rede Memorial Fund;" and Mr. Norman Lockyer, F.R.S., the late Rede lecturer, in London, at 6, Old Palace Yard, Westminster. The names of the subscribers will be found in our advertising columns.

WE have to record with great satisfaction the appointment of Mr. M. J. Barrington Ward, B.A., F.L.S., to be one of Her Majesty's Inspectors of Schools. Mr. Barrington Ward was a scholar of Magdalene Hall, and first of his year in Natural Science at Oxford. He has recently occupied the post of Science-master at Clifton College.

THE post of teacher of Chemistry at Clifton College will be vacant at the end of the present term.

AMONG recent deaths of persons eminent in Science, *Harper's Weekly* mentions that of Dr. Samuel Jackson, former Professor of the Institutes of Medicine of the University of Pennsylvania, which took place at Philadelphia on the 5th of April last. Dr. Jackson was born in Philadelphia in 1787, and was therefore eighty-five years of age. He held the position of active professor for twenty-eight years, and retired in 1863. He was well known as a physician and surgeon of great eminence, and for a long time occupied a leading position. He was also an author of some celebrity, and popular as a lecturer. His most important work was "The Principles of Medicine," first published in 1832, and which has gone through numerous editions.

A COMMUNICATION was presented to the National Academy of Sciences at Washington, at its annual meeting, on April 16 last, from Prof. Agassiz, dated Monte Video, February 26. In this he expresses his gratification at finding evident traces of glacial action in the vicinity of Monte Video, as shown by the occurrence of phenomena which were quite satisfactory to his mind. He leaves the question undecided as to the origin of the erratic boulders found scattered over the surface, but hopes that his further investigation in the southern hemisphere will enable him to supply the necessary data.

PROF. CORFIELD will commence a course of twelve lectures on Hygiene and Public Health at University College, London, on Tuesday next, at 12 o'clock.

AT the last exhibition of the Royal Horticultural Society an Interesting feature was introduced in the shape of prizes offered for the best dinner-table decorations. The competing tables were laid out in two tents in the gardens, and were an object of great attraction. Many of them were remarkable for the taste displayed in the arrragements.

A FUND was started some time ago to promote the investigation of the Wealden formation of Sussex, especially with reference to the question of the supposed underlying coal strata. Large subscriptions have already been received for this purpose; the Duke of Devonshire has promised 250*l*., and Lord Leconfield 100*l*. It is believed by many geologists that coal in large quantities may occur in strata beneath some of the longitudinal folds of the Wealden denudation, and form a continuation of the Belgian coal beds.

THE Ethnological Collection of the Oxford Museum has lately been enriched by the presentation to it of some North Australian spears, by Captain Halpin, of the *Great Eastern*. Captain Halpin, in his capacity as chief of the Expedition which laid the cable to Australia last year, visited Port Darwin, and there obtained these weapons. One of the spears has a stone head. The stone of which it is formed is a sort of shale. The head is large, very sharp, and of the unground type. The Oxford Ethnological series is, under the hands of Prof. Rolleston, becoming a very valuable and complete one indeed, and those who are in possession of authentic crania or weapons of interest from an ethnological view, cannot do better than contribute to it. Canon Greenwell has lately presented the whole of his valuable collection.

THE *American Naturalist* is responsible for the following story, which we could hardly have credited except on such authority:—"Central Park Museum.—Destruction of Mr. Hawkins' Restorations.—A *Times* reporter called yesterday on Mr. B. Waterhouse Hawkins in order to ascertain the truth of the allegations made in a communication which appeared in yesterday's *Times* in reference to the destruction of his restorations in the Central Park Museum. Mr. Hawkins stated that all he had done during twenty-one months to restore the skeletons of the extinct animals of America (of the *Hadrosaurus*, and the other gigantic animal, which was thirty-nine feet long), was destroyed by order of Mr. Henry Hilton, on the 3rd of May last, with sledge-hammer, and carted away to Mount St. Vincent, where the remains were buried several feet below the surface. The preparatory sketches of other animals, including a mammoth and a mastodon, and the moulds and sketch models, were destroyed. Mr. Hilton did this, said Mr. Hawkins, out of ignorance, just as he had a coat of white paint put on the skeleton of a whale which Mr. Peter Cooper had presented to the Museum, and just as he had a bronze statue painted white. Mr. Hilton told the celebrated naturalist who had come from England to undertake the work, that he should not bother himself with 'dead animals,' that there was plenty to do among the living. When the skeletons were dug up again, by order of Col. Stebbins, they were found broken in thousands of pieces. Prof. Henry, of the Smithsonian Institution, when he heard of this piece of barbarism, would not believe it. 'Why,' he exclaimed, 'I would have paid them a good price for it.' Mr. Hilton, however, preferred to destroy the work of the naturalist which had cost the City at least twelve thousand dollars." The proceeding appears to have met with universal reprobation from the Americans. The *Naturalist* refers by way of contrast to the record in our columns of the preservation of the great megalithic monument at Avebury, through the public spirit of Sir John Lubbock.

THE poorest flora in the world is probably that of the island of St. Paul in the Indian Ocean, an account of which appears in the "Verhandlungen der k. k. zoologisch-botanischen Gesellschaft in Wien" for 1871. It consists, as far as flowering plants are concerned, of six grasses, a sedge, a *Plantago*, and a *Sagina*. Of these the two latter only are undescribed species, and all the remainder have probably been introduced.

THE Acclimatisation Society of Auckland, New Zealand, has printed its fifth Annual Report. The efforts of the Society during the preceding year have been chiefly devoted to the introduction of insectivorous birds from England and Australia, and of freshwater fish. In both these respects the Society has met with greater success than in previous years, and appears to be performing work of great service to the colony. The gardens of the Society have also been considerably enlarged.

SEVEN parts are now published of the new edition of Griffith and Henfrey's Micrographic Dictionary, edited by Dr. Griffith, the Rev. M. J. Berkeley, and Prof. T. Rupert Jones, of which we have already noticed the issue of the first number. They bring down the articles as far as *Confervoideæ*.

DR. CHARLES C. ABBOTT has reprinted his elaborate and profusely-illustrated article on the "Stone Age of New Jersey," which has been running through several numbers of the *American Naturalist*.

THE Danish war steamer *Fylla* has been ordered by the Danish Government to take soundings and survey landing-places for the submarine telegraph line intended to connect Scotland with Canada *viâ* the Faroe Islands. It is to be hoped that these soundings will be accompanied by dredgings, and that they will be carefully made, as much of Dr. Carpenter's early researches in deep-sea dredging, which excited so much attention at the time and since, were made in the neighbourhood of the Faroe Islands.

THE earthquake in California on March 26 appears to have been felt over a very large area, and in some places to have been very severe. At Leone Pine, in the country north of the Mojane river, twenty-three people were killed, and thirty wounded; fifty large houses were destroyed, and the town is in ruins. Similarly Camp Independence, Inigo county, is in complete ruins, the earthquake having been most severe in that region. Large fissures are reported, miles in length, and 50 to 200 feet wide, and twenty feet deep, opened along the eastern base of the Sierra Nevada, near Big Pine Camp. At other places in the vicinity, the ground is heaved up in great ridges; large springs have stopped running, and others have broken out. Heavy snow slides have occurred in the Sierras, and large rocks rolled down the mountain side, blocking up the road. The shocks lasted at intervals from 2.20 to 6.30 A.M. Many people at Camp Independence were hurt, but none were killed. The shock was probably the heaviest south-eastward towards Arizona, in the desert country which has hardly any population.

THE April number of the *American Journal of Science* contains an account by Prof. Marsh, the indefatigable palæontologist, of his discovery of a new species of *Hadrosaurus*, a giant lizard; one of which, found in New Jersey, from its enormous size, constitutes one of the chief attractions of the Academy of Sciences of Philadelphia, where it is deposited. The present animal is scarcely one-third the size of the New Jersey specimen. It was discovered near the Smoky Hill River, in Western Kansas, and is named *Hadrosaurus agilis*.

ON THE MINERAL CONSTITUENTS OF THE BREITENBACH METEORITE *

THE Siderolite of Breitenbach was acquired for the British Museum in the year 1863. It was found (in 1861) at Breitenbach in Bohemia, at a spot not very far distant from the Saxon frontier, or indeed from Rittersgrün, in Saxony, a place in which a very fine mass that bears a close resemblance to the Siderolite of Breitenbach, was almost contemporaneously found. A little way to the west of the centre of the line joining Rittersgrün and Breitenbach lies Steinbach, a village in the environs of Johanngeorgenstadt, near Schwartzenberg; and here in 1751 was also found a mixed meteoric mass in which, as in the two already mentioned, iron, sponge-like in its structure, encloses siliceous minerals that do not present a familiar aspect. The three meteorites are, in fact, so similar to one another and so dissimilar to any others in European collections, that there can be little doubt they belonged originally to the same meteoric fall.

Stromeyer † in the year 1825 examined a siderolite in which he found as much as 61·8 per cent. of silica. This remarkable result, together with the numbers of his analysis, he interpreted as indicating the presence of a magnesian trisilicate, probably meaning thereby a sesquisilicate (magnesium epideutosilicate). The specimen which he analysed he described as coming from Grimma, in Saxony. This specimen was, in fact, a portion of a mass preserved in the collection of the Duke of Gotha, and doubtless believed by Stromeyer to be a portion of a stone which was known to have fallen in the middle of the sixteenth century in a wood near Naunhof, in the neighbourhood of Grimma. Chladni‡, however, held this view to be untenable, grounding his opinion on the completeness of the meteorite preserved at Gotha, both as regards its form and its crust, while he adds that the Naunhof mass must have been far too great to allow of its being transported, and, indeed, that it had never been rediscovered. It is in every way probable that the material Stromeyer really had taken to work upon was from a Saxon locality, and in fact a specimen from a fall, to which the Rittersgrün and Breitenbach siderolites belong. Breithaupt§ believes the fall in question to have been the "*Eisenregen*" which occurred at Whitsuntide, 1164, in Saxony, when a mass of iron fell in the town of Meissen ‖.

An inspection of a polished surface of either of these masses reveals the iron in patches of irregular form, which exhibit the characteristic crystalline structure of meteoric irons when etched. The interspaces are partly filled by meteoric pyrites (troilite) in small patches, recognisable by its pinchbeck brown colour, the rest of the surface being occupied by a greenish and greyish-brown crystalline magma. It is of the ingredients of the last-mentioned portion of the meteorite that I shall first speak. On treating the whole mass with mercuric chloride at 100° for some hours the iron and the troilite are dissolved, and the magma before alluded to remains unattacked. But it has now lost its compound structure, and is found to consist of three substances: (1) highly crystalline, bright green, or else greenish-yellow grains; (2) rusty brown, sometimes nearly black, sometimes also nearly colourless grains of a mineral that presents crystalline features, but on which definite crystalline planes are of great rarity; and (3) crystalline grains of chromite.

The first of these three minerals proved to be a ferriferous enstatite, or bronzite; the second is a mineral which corresponds in all respects, except its crystalline form, with the tridymite of Prof. Vom Rath. In respect of their forms, however, it is difficult to suppose that the two minerals are identical.

Bronzite of the Breitenbach Siderolite

The specific gravity of this mineral is 3·238, that of the silicates in the Steinbach siderolite, as determined by Stromeyer, having been 3·276, and as estimated by Rumler 3·23. The hardness is 6.

The blackened aspect of some of the bronzite was due to a mere superficial coating of iron oxide, arising doubtless from the oxidation of a portion of the nickeliferous iron. It was invariably found that this film was easily removed by hydrogen chloride, leaving the bronzite of a bright green colour, and that the action of the acid on the mineral extended no further.

* Abridged from a paper contributed to the Philosophical Transactions by Prof. Maskelyne, F.R.S.

‡ Berg. and. Hutt, Zeitung, xxi. p. 323

§ Feuer-Meteore, pp. 326 and 212

‖ Feuer-Meteore, p. 198

Two analyses of this mineral were made, the one by the hydrogen fluoride method of distillation*, the other by fusion with mixed alkaline carbonates, and the results were as follow:—

	I.	II.	Mean.	Oxygen.
Silicic acid	56·101	56·002	56·051	29·89
Magnesium oxide	30·215	31·479	30·847	12·34
Iron protoxide	13·583	13·295	13·439	2·97
	99·899	100·776	100·337	

These numbers correspond very closely with the formula ($Mg_{\frac{4}{5}}$ $Fe_{\frac{1}{5}}$) $Si\,O_3$.

Asmanite—a new mineral, being Silica crystallised in the Rhombic System, as a Constituent of the Breitenbach Siderolite.

The second mineral associated with the bronzite in this meteorite is free silica, possessing the lighter specific gravity presented by quartz after fusion, and crystallised in forms that belong to the orthorhombic system. To this mineral, which is distinct in its system and forms from the tridymite of Vom Rath, I propose to give the name Asmanite, A'sman being the Sanscrit term (corresponding to the Greek ἄκμων) for the thunderbolt of Indra. In bulk it forms about one-third of the mass of mixed siliceous minerals. The grains of this mineral are found mixed with those of the bronzite, after the iron, the troilite, and the chromite have been removed. They are very minute and much rounded, and, though entirely crystalline, they very rarely indeed present faces that offer any chance for a result with the goniometer; indeed out of the several thousands of these little grains comprised in some two grammes that were isolated of the mineral, it was only possible to find with a lens about a dozen specimens with sufficiently distinct crystallographic features; and of these only four or five proved to be available for examination and comparison. In several, however, the optic axes were plainly to be distinguished when properly examined with a Nörrenberg's polarising microscope; and by this means the angles given by planes belonging to zones otherwise too incomplete for a reliable result were brought into comparison on different crystals.

The parametral ratios of Asmanite are

$$a : b : c = 1{\cdot}7437 : 1{\cdot}0000 : 3{\cdot}3120.$$

The faces of the octaid forms are almost invariably rounded. Fair approximate measurements, however, of three of the tantozonal faces in one crystal were obtained.

That the mineral belongs to the rhombic and not to an uniaxial system is emphatically evidenced, independently of the measurements, by its optical characters, as shown in its very distinct and widely separated optic axes. As has been said, the first mean line is the normal of the face 1 0 0, that to face 0 0 1 is the second mean line. The first mean line is parallel to the axis of least optical elasticity, so that the crystal is positive in its optical character. The apparent angle, as measured in air, of the optic axes was approximately determined as 107° to 107° 30'. The axes for the red rays are slightly more dispersed than those for the blue.

The crystalline grains which constitute this ingredient of the meteorite, when first obtained, are of a rusty brown and sometimes even black colour; treatment for a short time with dilute hydrogen chloride, however, entirely removes this iron stain and leaves the granules in a state of colourless purity, in which state they are readily distinguished from the grains of the accompanying bronzite.

The specific gravity of the mineral gave the number 2·245. Its hardness is 5·5.

Two analyses were made by different methods, and the results are given below.

I. 0·3114 substance, distilled with pure hydrogen fluoride, gave 1·1136 gramme of potassium fluosilicate, 0·0035 gramme iron oxide, 0·0018 calcium oxide, and 0·0132 gramme magnesium phosphate.

These determinations denote the following percentages:—

Silicic acid	97·43
Iron oxide	1·124
Calcium oxide	0·578
Magnesium oxide	1·509
	100·641

* Philosophical Transactions, 1870, p. 189.

II. 0·2653 gramme of carefully selected substance, evaporated with an excess of ammonium fluoride, left 0·0021 gramme residue, chiefly iron oxide.

This determination denotes the following percentage composition:—

Silicic acid	[99·21]
Iron oxide, &c. . . .	0·79
	100·00

Besides the distinct cleavage parallel to the plane 0 0 1 already alluded to, and the other, less distinct, parallel to the planes of the form (1 0 1), there seem also to be divisional planes or, rather, surfaces along which the crystals break up with the greatest facility; even drying them on blotting-paper proving often sufficient to destroy the integrity of specimens that might otherwise seem to promise good results to the goniometer.

Partsch,* in his description of the Vienna Collection of Meteorites, identifies as a specimen of the Steinbach siderolite a fragment with a label, "Native iron, jagged and hackly, with quartz in grains and a yellow fluor-spar" (*gediegenes, zahnicht und zackicht gewachsenes Eisen mit körnichtem Quarz und gelblichtem Flussspath*).

Breithaupt†, in his paper describing the Rittersgrün Siderolite, makes its chief silicate to be peridot. It is doubtless bronzite. In addition to troilite and schreibersite, he records the presence of "another mineral, the composition of which is not yet determined."

It should be mentioned that, with a view to test the relative solvent action of alkaline carbonates on quartz and the meteoric silica, weighed portions of each were digested with a ten per cent. solution of sodium carbonate for ten hours at 100° C. under precisely similar conditions. Of the quartz 7·843 per cent. had dissolved, of the Breitenbach silica 9·437 per cent.

The Shalka Meteorite.

An examination of the Shalka meteorite, also detailed in the same memoir, gave as a result that this meteorite consists mainly of a bronzite of the formula $Mg_{\frac{3}{4}}\ Fe_{\frac{1}{4}}\ Si\ O_3$, and is therefore identical in composition with, though very different in appearance and structure from, that of the meteorite of Manegaum.

HEAT GENERATED BY METEORIC STONES IN TRAVERSING THE ATMOSPHERE

AS supplementary to my short article on the "Maximum Velocity of Meteoric Stones Reaching the Surface of the Earth" (NATURE, Sept. 14, 1871, vol. iv. p. 398), permit me to add the following observations in relation to the source and the amount of the heat generated by such masses in traversing the atmosphere.

It is well known that the observations of Glaisher, Petit, Daubrée, and others, establish the fact that these bodies enter our atmosphere with velocities which are truly planetary. For example, the meteorite of Orgueil moved with a velocity of at least 20 kilometres (12·43 miles) per second, while in other cases velocities have been observed which could not be observed at less than from 15 to 30, or even 40 miles per second. The enormous resistance encountered by such bodies in traversing the air (as we have seen in the previous article), speedily extinguishes this high velocity, so that they retain but a comparatively moderate velocity on reaching the surface of the earth.

Now, the "Dynamical Theory of Heat" assures us that whatever energy is lost by the moving body is transformed into heat, which is either retained by the body or is communicated to the air. The amount of heat thus generated can be estimated, provided the diminution of velocity and the mass of the meteoric stone are known. More than 23 years ago Dr. Joule pointed out this transformation of energy into heat as the true cause of the ignition of these extra-terrestrial masses in traversing the air (*Vide* Phil. Mag., 3rd Series, vol. xxxii., p. 349, May 1848).

According to Joule's experiments, one French unit of heat = 423·5424 kilogrammetres or units of energy. Hence, one

$$\text{French unit of energy} = \frac{1}{423\cdot5424} = 0\cdot00236104 \text{ French units of heat.}$$

If, therefore,

v = velocity of stone upon entering the atmosphere,
v_1 = ,, ,, ,, when near the earth's surface,
g = acceleration produced by gravity,
w = weight of moving stone in kilogrammes:

Then if v, v_1, and g are taken in metres per second, we have,

$$\text{Loss of energy} = w \cdot \frac{v^2 - v_1^2}{2g}.$$

This loss of energy transformed into heat =

$$0\cdot00236104 \times w \cdot \frac{v^2 - v_1^2}{2g} \text{ French units of heat.}$$

Assuming $g = 9\cdot80942$ metres per second, we have,

French units of heat generated $= 0\cdot000120345 \times w \times (v^2 - v_1^2)$.

This gives the total amount of heat evolved by the loss of energy.

Now, if we knew the distribution of the heat thus generated, it would be easy to estimate the increase of temperature which it would occasion in the matter to which it is imparted. If we assume all of the heat evolved to be retained by the moving body, it is evident that the increase of temperature ($v^2 - v_1^2$ being the same) is inversely proportional to the product of the weight into the specific heat of the moving mass.

Hence, if c = specific heat of stone in relation to water as unity, we have,

$$\text{Increase of temperature in C}^\circ = 0\cdot000120345 \times \frac{w(v^2 - v_1^2)}{w \times c}; \text{ or}$$

$$\text{Increase of ,, ,,} = 0\cdot000120345 \times (v^2 - v_1^2) \times \frac{1}{c}. \quad (a)$$

Under the assumption that all of the heat generated is retained by the moving mass, it is obvious that w is eliminated; for, while the heat evolved varies as w, the mass to be heated also varies as w; so that the weight is without influence, in so far as increase of temperature is concerned.

In order to apply this formula to any given case, we must know v, v_1, and c in relation to the moving stone. Perhaps we should not be over-estimating v by assuming it to be 30 kilometres per second, or nearly equal to the velocity of the earth in its orbit. In like manner we should certainly not be under-estimating v_1 by assuming it equal to 500 metres per second. Substituting these values in formula (a), and we have,

$$\text{Increase of temp. in C}^\circ = 0\cdot000120345\,(30000^2 - 500^2) \times \frac{1}{c}; \text{ or}$$

$$\text{Increase of ,, ,,} = 108530 \times \frac{1}{c}.$$

Finally, in the absence of experimental results in regard to the specific heat of meteoric stones, we are certainly not under-estimating c by assuming it equal to 0·22.

Substituting this value of c in the last equation, and we have,

Increase of temp. in C° = 492,184°.

Of course, by far the larger portion of the heat generated by the loss of energy of the moving stone would be imparted to the air along its trajectory; but assuming that only $\frac{1}{100}$th part of it is retained by the stone, it would be more than sufficient to account for the phenomena of fusion and detonation which frequently accompany the transit of such bodies through our atmosphere.

In the case of small masses, it is clear that their high velocities would be more rapidly extinguished by the resistance of the air than is the case with large masses. In the small mass the transformation of energy into heat being accomplished in a shorter time, a greater amount of the evolved heat would be retained by the stone than in the large mass whose velocity is more gradually checked by the resisting medium.

Hence, when the smaller masses plunge into the upper atmosphere, the matter may be volatilised or utterly dissipated by the intensity of the suddenly-evolved heat. In this minutely-divided condition the material of the stones would float about in the atmosphere, and ultimately reach the surface of the earth in the form of meteoric dust.

It is well known that the observations of Benzenberg, Quetelet, Herrick, Newton, and others, assign to the so-called "falling stars" velocities equal to, if not surpassing, the velocities of meteoric stones. According to the foregoing suggestion, these may be nothing more than small meteoric stones which are volatilised in the upper regions of the atmosphere long before reaching the surface of the earth.

Thus, the phenomena of the occasional fall of meteoric stones and the almost incessant appearance of the falling stars which nightly furrow the celestial vault, may be correlated with the

principle of transformation of energy. At all events, all the luminous, thermic, and detonating phenomena attending the fall of such bodies seem to be fully accounted for by the enormous amount of heat thus generated by their passage through the atmosphere.

JOHN LE CONTE
University of California

SCIENTIFIC SERIALS

Annalen der Chemie und Pharmacie, November 1871. This number opens with a lengthy paper by Græbe and Liebermann on anthracene derivatives; they have studied in detail anthracene carbonic acid, and the behaviour of anthraquinine with phosphoric chloride and potassic hydrate. They have also experimented with the anthraquinine sulpho-acids; at the present time researches on this subject possess considerable technical interest, as it is from disulphanthraquinonic acid that artificial alizarin is prepared, which seems to be fast supplanting the use of the madder root in dyeing. Böttger and Petersen follow on a subject nearly allied to the former, "on the compounds of anthraquinone containing nitrogen." Zinneman contributes a paper on an improvement in the method of distillation; the method is somewhat similar to that usually employed in chemical laboratories, that is to cause the vapour to pass up a long upright glass tube on which several bulbs have been blown, the exit tube being at right angles nearly at the top; the new portion of the apparatus consists in placing in the long tube a number of bell-shaped cages made of platinum wire gauze, which fit closely to the sides of the tube, and through which the vapour must pass or filter as it rises in the tube. With this apparatus the author has made an extensive series of experiments on the purification and determination of the boiling points of some of the most important of the ethyl compounds, on various acids of the same series, on the separation of propyl and butyl alcohols from the products of fermentation, and on the separation of the iodides of ethyl, propyl, and butyl. Judging by the results of these experiments, the new contrivance seems to work extremely well, and to be an improvement on the original form of apparatus. Several short papers complete this number, but they are not of extreme interest.

Journal of the Chemical Society, March 1872.—The composition of the natural tantalites and niobates forms the subject of a very important paper by Rammelsberg. Numerous analyses of various minerals containing the two rare elements, tantalum and niobium, are given, the results of which, however, cannot be usefully condensed.—Dr. Tilden presents a note "On the crystalline principle of Barbadoes Aloes;" the author has obtained a chloro-substitution product corresponding to the bromo-derivative, described some years since by Dr. Stenhouse, that is aloin in which three atoms of hydrogen are replaced by chlorine. The remainder of this number is occupied by the abstracts of foreign papers, many of which are of great interest.—Dr. de Coppet finds that supersaturated solutions of sodic sulphate can be prepared by dissolving the anhydrous salt in cold water; it is, however, necessary that the anhydrous salt should be heated above 33°, and cooled out of contact with the air, as it is found that the anhydrous sodic sulphate, obtained by drying the ordinary salt (containing ten molecules of water) at a temperature lower than 33°, always acts as a nucleus in determining the crystallisation of a supersaturated solution of this salt. From this it appears that from crystallised sodic sulphate different bodies are obtained depending on the temperature at which the salt is dried.—A long abstract of Linnemann's important paper "On an improvement in the method of fractional distillation," and also of his researches on the normal propyl alcohol and its compounds are here given.—Another curious example of the lowering of the boiling point of mixtures of water and other liquids forms the subject of another abstract. Is. Pierre finds that a mixture of water and butyl iodide distils at 95°–96° (butyl iodide boils at 122·5°), and that a constant mixture of 79 parts of iodide and 21 of water is found in the distillate. Ethylic iodide (B.P. 72°) and water distil at 66°, only 3 to 4 per cent. of water condensing with the iodide. The abstracts as a whole are shorter and more condensed than they were originally; in some cases this must be regretted, though in others it is, perhaps, an advantage.

THE *Quarterly Journal of Microscopical Science* for April 1872, contains memoirs on the Development of the Enamel in the Teeth of Mammals, as illustrated by the various stages of growth demonstrable in the evolution of the fourth molars of a young elephant, and of the incisor teeth in the fœtal calf, by Prof. Rolleston, M.D. This paper is a reprint.—Note on Immersion Object-glasses for the Microscope, by Dr. Royston Piggott, chiefly directed towards the assertion that the aperture of an immersion lens can never exceed 80°, which this author denies.—Observations of Pathological Changes in the Red Blood-corpuscle, by J. Braxton Hicks, M.D.—On the Artificial Production of some of the principal Organic Calcareous Formations, by Prof. Harting, of the University of Utrecht. This is an abridged report of researches undertaken with the view of producing, independently of living organisms, certain calcareous formations, which are met with in animals as integral parts of their skeleton, and this by causing calcium carbonate and phosphate to combine in the nascent state with organic substances.—On the Peripheral Distribution of Non-medullated Nerve-Fibres, by Dr. E. Klein; the third part of a memoir, of which the previous portions appeared in this journal. It treats of the relation of the non-medullated nerve-fibres to small arteries, small veins, and to capillary vessels in the muscular substance of the frog's tongue; and the termination of nerve-fibres in the ciliated duct in the tail of the rabbit.—On the Structure of Tendon, by J. Mitchell Bruce, partly in support and partly in con-troversion of the views of Boll, as detailed in Max Schultze's *Archiv*.—The Embryology of Chrysopa, and its bearing on the Classification of the Neuroptera, by A. S. Packard, Jun., M.D. Reprinted from the *American Naturalist*.—Preliminary notice of Researches on the Anatomy of the Serous Membranes in Normal and Pathological Conditions, by Dr. E. Klein and Prof. Burdon Sanderson, forming a part of investigations on infectious diseases, undertaken for the Medical Department of the Privy Council. These investigations relate to more than 250 animals, especially rabbits and guinea pigs, many frogs, several cats, dogs, some rats, and one monkey.—The remainder of the journal is occupied with abstracts, notices, and reports.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 16.—"On the Specific Heat and other physical characters of Mixtures of Methylic Alcohol and Water, and on certain relations existing between the Specific Heat of a Mixture or Solution, and the Heat evolved or absorbed in their formation," by Dr. A. Dupré.—"On Supersaturated Saline Solutions," Part III., by Charles Tomlinson, F.R.S., and G. Van der Mensbrugghe.—"Remarks on the Sense of Sight in Birds, accompanied by a description of the Eye, and particularly of the Ciliary Muscle in the genus *Raptores*," by Mr. Robert Lee.—Supplement to Mr. Lee's communication on the Sense of Sight in Birds. A Description of the Eye in *Rhea americana*, *Phœnicopterus antiquorum*, and *Aptenodytes Humboldtii*.

Geological Society, May 8.—Mr. Joseph Prestwich, F.R.S., in the chair.—The following papers were read:—1. "Notes on Atolls or Lagoon Islands." By Mr. S. J. Whitnell. The author commenced by indicating certain facts which lead him to think that the areas of atolls are not at present sinking, and referred to one instance (that of Funafuti or Ellice Islands), in which he thought there were signs of a slight upward movement. He noticed the occurrence of a furrowed appearance, or a series of ridges or mounds, in some islands, each of which he regarded as produced by a single gale. He also described a freshwater lagoon, about three miles in diameter, as occurring in the Island of Quiros. Mr. Thorpe was acquainted with the atolls around the coast of Ceylon, and thought that the local traditions, untrustworthy as such sources usually were, might afford some evidence as to the date of their origin. The tradition of Ceylon was that the Maldive and Laccadive Islands had within the memory of many been connected with Ceylon. If this were so the evidence was in favour of the area being one of subsidence. Mr. D. Forbes, when in 1859 he spent some months in the Pacific, had been requested by Mr. Darwin to examine into the evidence as to the origin of these atolls by elevation, and had found that the asserted cases of the existence of masses of coral at a considerable elevation above the sea merely arose from blocks having been transported inland by the natives. Though, however, there was no evidence of elevation, it was still possible that such had in certain cases taken place, as there were still active volcanoes in this region. The freshwater lakes he attributed to the drainage of the islands

2. "On the Glacial Phenomena of the Yorkshire Uplands." By Mr. J. R. Dakyns. The author stated that in Derbyshire and Yorkshire, south of the Aire, there is no glacial drift on the eastern slope of the Pennine chain, except where it is broken through by the valleys of the Wye and of the Aire and Calder. The basis of the Aire and the country northward are thickly covered with drift, which contains no rocks foreign to the basis, and thus points to formation by local action. The author ascribed this to the glaciation of the country in part by glaciers, and in part by a general ice-sheet. Evidence of the latter he finds in the fact that drift occurs only on one side of the valleys, namely, on the lee-side of the hills with respect to the source of the drift materials. Traces of the action of glaciers are the great amount of scratched and rounded pebbles in the mounds of drift, which increases in proportion to the distance from their source: the presence of great piles of drift at the junction of valleys, as if by the shedding of the lateral moraines of two glaciers; and the existence of mounds of pebbles and of an alluvial deposit wherever a rock-basin crosses a valley. The Kames or Eskers, which are frequent in the valleys, he ascribed to the deposition of moraines in the sea instead of on land. Prof. Ramsay agreed with the author as to the existence of these rock-basins in the Yorkshire area, and as to the absence of marine drift on great part of the slope of the Pennine chain. The terminal moraines had to some extent become obscured by the washing of soil by rain; but their ancient existence in many of the Yorkshire valleys was indisputable. The features of the country, were, moreover in many instances such as could not be reconciled with the deposition of the drift by marine action. 3. "On a Sea-coast Section of Boulder-clay in Cheshire." By Mr. D. Mackintosh, F.G.S. The principal object of the author was to draw attention to the fact of the occurrence of numerous sea-shells in a lower boulder-clay at Dawpool, as thoroughly glacial in its appearance, structure, and composition, as any clay to be met with along the shores of the Irish Sea, and differing in no essential respect from the *Pinel*, which runs up the slopes and valleys of the Lake District. He pointed out a number of very important distinctions between the Lower and Upper Boulder-clays of Cheshire, referring especially to the light grey or blue facings of the fractures of the latter. He gave a list of a number of large boulders, greenstone and Criffell granite predominating, though among the smaller stones Silurian grit was most prevalent. The author likewise explained the mode of striation of the stones found in the clay, and the position they occupied in reference to their flattened surface. The paper was illustrated by samples of the two clays, a number of shells in various states of preservation, and about forty specimens (most of them named and their parentage assigned) of Silurian grit and argillite, greenstone, several varieties of felstone and porphyry, felspathic breccia, Criffell and Eskdale granites, and granites of unknown parentage, Wastdale or Ennerdale syenite, quartz, Carboniferous Limestone, chalk flints (?) local gypsum, sandstone, &c. In a letter Mr. Searles V. Wood, Jun., stated that he regarded the Boulder-clay containing the shells as later than the newest of the East-Anglian beds, and the Upper clay as probably equivalent to the Hessle clay. The fragmentary shells sent had been determined by Mr. J. Gwyn Jeffreys, who found eleven species represented among them, and stated that they agreed with the shells from Moel-Tryfaen and Macclesfield. He remarked especially on the occurrence of *Astarte borealis*, a species now extinct in the British area. Prof. Ramsay remarked, with regard to the Bridlington beds which had been cited, that they were probably preglacial, and not glacial. He thought that eventually it would be proved that during the Glacial Period there had been several oscillations in this country both in level and temperature. With respect to temperature, the calculations of Mr. Croll showed the extreme probability of such variations being due to astronomical causes; and these were best illustrated by reproducing his figures in the form of a diagram, showing the curves and oscillations of temperature. 4. "On Modern Glacial Action in Canada.—II." By the Rev. William Bleasdell, M.A. In this paper the author communicated some facts illustrative of the action of ice in Canada, in continuation of a former paper. Fidlar's Island, in the rapids of the river Trent (flowing into the head of Lake Ontario), has been removed within the last eighteen months. Patrick's Island, a mile lower down, is also rapidly disappearing. Salmon Island, in the Bay of Quin e, between Amherst Island and the mainland, which had an area of about an acre fifty years ago, has disappeared, leaving a shoal with about four feet of water over it; and three neighbouring islets, known as The Brothers, are in course of removal. The removal of these islands is due to the action of drift-ice. The author also referred to the formation of ground-ice in the Canadian rivers. Prof. Ramsay mentioned that Sir William Logan had informed him that shore-ice in Canada, charged with boulders, had been known to produce grooves on the face of cliffs as well marked as those of glacial times. He had also mentioned the case of a boulder transported by ice which was of such a size as to have occasioned the wreck of a vessel which had struck upon it.

Mathematical Society, May 9.—W. Spottiswoode, Treas. R.S., in the chair.—Mr. J. W. Glaisher gave an account of his paper "On Functions with Recurring Derivatives." Mr. Tucker (Hon. Sec.) read portions of communications from Prof. J. Clerk Maxwell, on Equations of Motion, and on the Transformation of Solids.—Prof. Clifford made some remarks on a theory of the exponential function derived from the equation $\frac{du}{dt} = pu$. Prof. Cayley, Dr. Hirst, Mr. S. Roberts, and others, took part in a subsequent discussion on the degenerate forms of curves.

Chemical Society, May 16.—Dr. Debus, F.R.S., vice-president, in the chair.—"On the Influence of Pressure upon Fermentation," Part I., by Mr. H. T. Brown. The results of his experiments were that under diminished pressure the amount of gas unabsorbed by potash is greatly increased, and that it contains a proportionally large amount of hydrogen. Acetic acid and aldehyde are also formed under these circumstances, so that it would seem that water is decomposed during the alcoholic fermentation, especially when it takes place under diminished pressure. Papers "On the Electrolysis of Sugar Solutions," by Mr. H. T. Brown; "On the determination of the solubilities and specific gravities of certain Salts of Sodium and Potassium," by Messrs. D. Page and A. D. Keightley; and "An examination of the recent attack on the Atomic Theory," by Mr. Atkinson, were then read. An animated discussion on the Atomic Theory ensued. Mr. C. O'Sullivan then read his elaborate memoir "On the transformation products of Starch."

Anthropological Institute, May 20.—Dr. Charnock in the chair.—Mr. J. Bonomi exhibited and described a new instrument for measuring the proportions of the human body, being specially applicable to the identification of criminals, and adapted for a rapid and very easy method of measurement in military and other large establishments.—A paper was read by Mr. George Harris, V.P., "On Moral Irresponsibility resulting from Insanity." He concluded that persons are not responsible for their actions in cases where they labour under delusions to such an extent that their conduct is not only influenced, but determined, by their belief, although they may still continue to reason correctly. Irresponsibility should be allowed also in those cases where they are impelled by irresistible morbid impulses; and where from disorders of the nervous system they are suffering from violent and uncontrollable irritability. He criticised the legal definition of irresponsibility in cases of that nature. As to suicide affording a proof of insanity, that must depend on the circumstances of each particular case. The author pointed out the contradictory theories laid down respecting insanity, and alluded also to the conflicting opinions expressed by medical men.

Geologists' Association, May 3.—James Thorne, F.S.A., vice-president, in the chair. "On Columnar Basalts," by Mr. John Curry. As a preliminary, the process of the formation of columnar mud was briefly described, the analogy between this process and that of the formation of columnar basalt being such that the same diagrams served for illustrations in both cases, though, in the former case, heat penetrates the fine clayey sediment, and produces columns of dried mud; in the latter, cold advances into the molten lava, and changes it into solid rock, which frequently has a rude but sometimes a perfect columnar structure. Hexagonal columns are the most perfect. In reference to the production of these columnar structures, the chief and most notable conditions are unequal temperatures, which the author designated heat and cold, closely situated at the contact surfaces of dissimilarly constituted bodies. In the above instances the dissimilar bodies in surface contact are, first, the atmosphere and fine clayey sediment; second, the oceanic water and the molten lava. While the solidifying of the lava is being effected, the solid and molten parts may be considered as distinct bodies. It is at and near the surface contacts that the

exchanges of heat are most efficient in giving structure to the forming body. The actions of heat and cold, having a directive influence in the formation of hexagonal basaltic columns, were shown in the illustrations. In the concluding part of the paper the large surface contact of the ocean with the bed on which it rests, and the contact of the atmosphere with the land and water surfaces, were adverted to as areas where the exchanges of heat had done and were now doing much work in producing structures. Jointage, cleavage, and various other rock structures are ascribed as being mostly due to such work. Ice structure is another marked example. It bears a striking analogy to the hexagonal columnar structure of basalts, inasmuch as it often breaks up into columns by slow melting. The ice of a lake sometimes shows such a breakage when it melts in the spring.—"On a visit to the Diamond Fields of South Africa, with notices of geological phenomena by the wayside," by Mr. John Paterson. On the geological questions connected with th diamond fields the author propounded some new views based on a minute and careful examination of the appearances which presented themselves to him on his visit to the diamond-fields. He discredits the theories which would refer the presence of diamonds in Grequaland West to any distant sources; and thinks the evidence incontestable that the marl soil, as he named it, in which the gems are now found, is the true matrix soil of the diamond. This marl soil he considers to be the metamorphosed carboniferous shales of the country, and the change which has worked upon these shales, by which they have been transformed from the black carboniferous shale into the whitish ashy marl in which the diamonds are found, he attributes to intrusions of greenstone trap, which traverse that country from N.E. to S.W. in continually recurring dykes. Mr. Paterson gave some very interesting details of the extent and richness of the diamond diggings in South Africa, and in his picture of the Gong-Gong and Delport Diggings as "Great Rushes" in digger's phrase, resembling in extent and richness Colesberg Kopje, but now nearly worked out, not by the hand of man in a few years, but by the angry waters of the Vaal River through many ages, he found much groundwork of hope that the diamond discoveries of South Africa are to be no fleeting passing industry, but a continuous employment, not only for many years but for many ages.

Society of Biblical Archæology, May 7.—Mr. R. Cull, F.S.A., in the chair.—"On Underground Jerusalem; more particularly in reference to the Plateau of the Haram es Shereef." By Mr. William Simpson. The paper described Omar's search under the guidance of Sophronius, the patriarch of Jerusalem, for the site of the Temple, as one of the first explorations into the topography and archæology of the Holy City. The transference of holy places from one point to another was explained as involving confusion and adding to the difficulties of arriving at reliable facts. The principal theories respecting the site of the Temple and the Holy Sepulchre were defined, and their merits touched upon so far as to indicate the progress of the questions connected with them. The importance of a careful study of the various styles of building in the Haram Wall was pointed out so as to get a date, if possible, as a ground upon which to start. A most interesting part of the paper was a description of the Great Sea, excavated out of the solid rock, under the Temple site, and the supply of water to it from the pools of Solomon near Bethlehem. The great importance of the water system for the Temple uses having an essential bearing on the question of the topography, and the question was still one which required further knowledge and study to arrive at a definite result.—"On the so called Moabite Stone, described in a late Letter to the *Times*." By Mr. B. G. Jenkins. The author considered that the letter and the inscription bore their own condemnation; for the stone could not be Moses' memento of the conquest of a land he never attacked.—"Observations on the dimensions of the Great Pyramid and the Royal Coffer." By Solomon M. Drach.

PARIS

Academy of Sciences, April 29.—M. Chasles read a paper containing theorems relating to the obliques drawn through the points of a curve under angles of the same size.—M. F. Lucas communicated some general theorems on the equilibrium and movement of material systems.—M. L. Melsens presented a note on some effects of the penetration of projectiles into various media, and on the impossibility of the fusion of leaden bullets in the wounds produced by fire-arms.—A memoir was read on the electrical jet in rarefied gases, and especially on its mechanical power, by MM. A. de la Rive and Sarasin. Their experiments showed that the velocity of rotation of the jet diminishes as the density of the gas is increased, but not in the same proportion, and that the jet possesses considerable mechanical force.—MM. P. A. Favre and C. A. Valson presented a continuation of their memoir on crystalline dissociation, containing the second part of their investigation of the alums.—M. Fizeau presented a report on a memoir by M. Croullebois on the elliptical double refraction of quartz.—A continuation of M. P. Desains' researches upon the reflection of heat was read, and a note by M. D. Gernez on the absorption-spectra of selenium and tellurium, their protochlorides and protobromides, and of the protobromides of iodine and alizarine were presented by M. H. Sainte-Claire Deville.—Several papers and notes on auroras were read, including the continuation of M. J. Silbermann's memoir on the causes and laws of auroras, a note by Father Denza on auroral phenomena observed in Italy in March and April 1872, and a note by M. Guillard on indications of an aurora borealis observed at Lyons on April 8.—A second note by M. W. de Fonvielle on the hypothesis of the magnetisation of the sun was also read.—M. Delaunay presented a note by M. G. Héraud on the tides of lower Cochin China, with especial reference to the determination of the diurnal and semi-diurnal waves.—A note by M. Chapelas on a meteor observed at Rheims on the night of April 19-20, and one by M. Perris on a meteor seen at Agde on the evening of April 24 were read.—M. Aimé Girard presented an investigation of the salt marshes and salt industry of Portugal, in which he describes the details of the extensive manufacture of sea-salt carried on in that country.—M. Bussy presented a note by M. J. Personne on the presence of selenium in the sulphuric acid manufactured in France.—A note by the Abbé Laborde on the action of oxygen upon certain vegetable infusions was communicated by M. Pasteur. The author, after hermetically sealing a vegetable infusion in a glass vessel, and keeping it for a month unchanged, produced from it successive small quantities of oxygen by electrolysis. The infusion still remained unaltered, notwithstanding the replacement of the vacuum by an atmosphere of oxygen; but when the vessel was opened to the air vegetation soon made its appearance.—M. Pasteur also communicated a note by M. Griessmayer on the question of the assimilation of ammonia by yeast.—A note by M. H. Byasson on the physiological action of formic æther was presented by M. Robin.—M. Blanchard presented a note on the appearance of unusual numbers of *Bibio hortulanus*, a dipterous fly, in Paris.—A paper by M. P. de Gasparin on the constitution of clays was read. This paper contained an analysis of a very fertile clay soil from near Nîmes.—M. de Quatrefages communicated a note by M. E. Rivière on the human skeleton discovered in the caverns of Boussé-Roussé, in Italy, on March 26, 1872. This skeleton, which was associated with unpolished flint implements, presents no simian characters, and the cranium most nearly resembles those of Cro-Magnon.

May 6.—M. Chasles presented a note by M. H. Durrande on the general properties of the displacement of a figure of variable form.—A note by M. T. D'Estocquois on the movement of water in drains was read.—M. J. Bourget read a memoir on the economic coefficient in the thermodynamics of permanent gases.—M. Wurtz presented a note by M. G. Salet on the light emitted by the vapour of iodine, in which the author stated that that vapour may be heated to redness.—A letter from M. Tacchini to M. Faye, with regard to the Society of Italian Spectroscopists, and a reply to some of the statements contained in it by M. Faye, were read. They contained a discussion of various matters connected with our knowledge of the sun.—A note on atmospheric ozone by M. L. Palmieri was presented by M. C. Sainte-Claire Deville. The author stated that air, by passing through a glass tube, ceases to colour iodised starch paper. M. Sainte-Claire Deville confirmed this statement from M. Houzeau's observations.—A letter from M. Donati on auroras was communicated by M. Delaunay.—M. Le Verrier presented a note by Father Denza on a sand-shower which fell in Italy during the night of the 19-20 April.—A letter by M. Silbermann on the relations between meteorological phenomena and volcanic eruptions was read.—A note was read by M. C. Daniel on a process of decorative painting upon tin, and on this M. Dumas made some remarks.—M. Frémy presented a note by M. Prinvault on the transformation of pyrophosphates into phosphates by the action of boracic and sulphuric acids.—A note by M. Yvon on

the quantitative determination of copper by cyanide of potassium was communicated by M. Bussy. This note relates to one on the same subject by M. Lafollye, read on April 22; M. Yvon states that the reaction then employed was indicated in 1859 by M. Buignet, points out certain inaccuracies in M. Lafollye's paper, and describes a process of his own.—M. Wurtz presented a note by MM. C. Girard and G. de Laire on the formation of diphenylamine with reference to a recent note by MM. Dusart and Bardy.—M. Arrez forwarded a letter relating to his process of treating vines attacked by *Phylloxera vastatrix*, and upon this M. Dumas made some remarks.—Prof. Milne-Edwards presented a note by M. A. F. Marion on the reproductive organs of *Oria Armandi* Clap.—M. Bouley presented a note by M. S. Arloing on the nature of the blood-globules; and M. C. Robin some investigations by M. P. Bouland on the normal curvatures of the rachis in man and animals.—M. Ziegler presented a paper on a physiological fact observed in leaves of *Drosera*, containing some very curious observations on the effects produced on that plant by albuminoid substances after contact with the human hand.—M. Paul Gervais described the lower jaw of a new species of fossil ape from the lignites of Monte Bamboli in Italy. He regards this animal as forming a new genus standing at the end of the series of anthropomorphous apes after the gorilla and before the baboons and macaques. He gives it the name of *Oreopithecus Bambolii*.—M. Delesse communicated an investigation of the deformations which the French geological formations have undergone.—A note on the granite, sand, and clay with flints of the department of the Seine and Oise, by MM. Potier and Douvillé, was read, as also a paper on the valley of the Vezère, by M. F. Hément. The latter, communicated by M. de Quatrefages, contains accounts of traces of prehistoric man found in the valley.

BERLIN

German Chemical Society, May 13.—Dr. Bulk reported on the action of fuming sulphuric acid on aniline blue. He obtained tri-phenyl-rosaniline, in which four molecules of SO_3H replace four atoms of hydrogen, Nicholson's process yielding conjugated acids with from one to three molecules of SO_3H. Hofmann's violet behaves in a similar way to fuming sulphuric acid.—C. Scheibler stated that Erlenmeyer's observations on the non-existence of Gerhardt's para-thionic acid have been previously made by himself.—C. Rammelsberg has analysed a beautifully crystallised specimen of cast iron, confirming thereby his view that the various commercial grey and white irons are isomorphous mixtures of the pure element with combined carbon, and with non-combined carbon.—Dr. A. W. Hofmann reported on researches made by Dr. Geyger and himself on the action of aniline on azo-diphenyl-diamine $(N_3(C_6H_5)_2H)$ namely:—$C_{12}H_{11}N_3 + C_6H_7N = C_{18}H_{15}N_3 + NH_3$. The body, violet and soluble in alcohol, combines with one atom of HCl. Its formation and constitution correspond to the magdala red which has been obtained through the action of naphthyl-amine on azo-dinaphthyl-diamine. The body has the same composition as violaniline, obtained by oxydising pure aniline, when three molecules are condensed into one by losing six atoms of hydrogen. Azo-toluyl-diamine, $N_3(C_7H_7)_2H$, treated with aniline, gives rise to an analogous compound, having most likely the composition of rosaniline, $C_{20}H_{19}N_3$, from which it seems, however, to differ. A colouring matter recently offered in the trade, under the name of saffranine (mixed with large quantities of carbonate of lime), dissolving with a yellowish red in water, with a violet colour in concentrated hydrochloric, with a green colour in concentrated sulphuric acid, has been obtained in a similar manner; a mixture of aniline and toluidine being exposed to the action of nitrous acid and afterwards oxydised. Its chloride contains $C_{20}H_{20}N_4HCl$, the formula of which corresponds in appearance to a salt of amido-rosaniline, although its constitution is most likely very different. Perkins' analyses of mauveine agree with the formula of phenylated saffranine, $C_{26}H_{24}N_4$; and some of its reactions, notably its behaviour to hydrochloric and sulphuric acid, coincide with this suggestion, these acids producing violet and green colours as with saffranine. But it is not easy to understand how the fourth atom of nitrogen should enter into mauveine under the ordinary conditions of its formation.—Th. Petersson published the analysis of a metasilicate of sodium, $Na_2SiO_3 + 5$ aq.—Barl and Hübner found that nitrobenzol and similar substances form hydrocyanic acid when fused with potash. A similar observation has been published by Wöhler in 1828.—Geromont has obtained isobutyric acid from bibromo-pyrotartaric acid.—Michaelis found PCl_3Bo_2 to form unstable combinations with Br_2 and Br_4, comparable to the addition of water of crystallisation to a saturated compound.

BOOKS RECEIVED

ENGLISH.—Conversations on Natural Philosophy, 14th edition: Mrs. Marcet (Longmans).—The Geometry of Conics, Part I.: C. Taylor (Deighton and Bell).—Esse and Posse, a comparison of Divine eternal laws and powers: H. T. Braithwaite (Longmans).

FOREIGN.—Deutscher Universitäts Kalender für das Sommer-Semester, 1872: Dr. F. Ascherson, Berlin.—Sonnensystems: Meibauer.

THURSDAY, MAY 30, 1872

BOTANY IN THE OXFORD NATURAL SCIENCE SCHOOL

THE merits and demerits of the "Notice by the Board of Studies for the Natural Science School of the University of Oxford" will by this time have been abundantly discussed among all circles of teachers of Natural Science. That the former preponderate over the latter will hardly admit of a question; and if we once more call attention to the defects of the present "Notice," it is only in order that, by full and free discussion, a thoroughly satisfactory scheme may be at length elaborated. We have already pointed out the subordinate part which Botany plays in the programme, and this defect it is our present object to illustrate more at length. We imagine that the object of the framers of the scheme must have been to lay down in the Preliminary Honour Examination a foundation which will serve to give a solid basis for any superstructure that may be raised upon it—in other words, to supply the student with an adequate mental training to prepare him for whatever special branch he may afterwards take up. Let us see how this works in the case of Botany. The Natural Sciences which will be most useful to the future botanist in enabling him to gain a comprehensive insight into his own subject. are the outlines of Animal Physiology, Geology, and Organic Chemistry. Of not one of these subjects need he necessarily possess any knowledge in order to pass the Preliminary Honour Examination; but, on the other hand, must read up Mechanics, Physics, and Inorganic Chemistry. It seems to us a mistake to make the physical side of Science of such preponderating weight in the preliminary examination, to the entire exclusion of the biological.

If we now turn to the Final Examination in Biology, we still find that although it is specially stated that under Biology are included both Zoology and Botany, yet that his own special subject is still kept entirely in the background. Among the "list of books recommended for use in the preparation for the General Examination in Biology" are a number in General Anatomy and Histology, Comparative Anatomy, Human Physiology, Comparative Physiology, and the General Philosophy of Biology, but not one in any department of Botany, with the exception that in a foot-note we are informed that under the term "General and Comparative Anatomy and Histology" "vegetable structures" are included. Otherwise the examination is exclusively one, not in Biology, but in Animal Physiology and the Comparative Anatomy of Animals. The works, indeed, on this subject to which the intending botanist is referred would require a very long course of study to master. The list is so extensive, and the range so great, that it must necessarily have the effect of deterring many an aspirant for distinction in the Natural Science School.

The arrangements under the special subject of Botany seem to us no less open to objection. The first impression conveyed is that the subject can only have been admitted at all under protest, and that it is looked upon as of decidedly subordinate importance to all the rest. While Mineralogy and Crystallography have three pages devoted to them, Geology five, and Zoology four, Botany is compressed into one, and the information and assistance given is of the most meagre. The books "provisionally recommended" are ten in number; but what is meant by a provisional recommendation we do not know. The Board must surely have made up its mind as to whether the works are to be recommended or not; and we venture to say that some even of these ten are books that ought not to have obtained the sanction of such a body. Not only does the list err on this side; but books which are familiar to every botanical teacher as the best elementary works are not to be found in it. It must be remembered that, as far at least as structural and systematic botany are concerned, the student is now at the outset of his career; and yet what will be thought of a list of books recommended to his notice which makes no mention of either Oliver's "Lessons" or Lindley's "School Botany"? In Geographical and Geological Botany, the recommendations comprise the portions bearing on these subjects of Henfrey's "Elementary Course" and Balfour's "Manual of Botany." Now, we think it is generally admitted that these are the least satisfactory portions of the works quoted; and we have no hesitation in saying that the student will gain from them no adequate knowledge of the present state of these sciences. Not a hint is given of the existence of original memoirs or essays, such as those of De Candolle, Grisebach, Heer, Unger, Hooker, and Carruthers. Again, in the other special subjects the excellent practice is adopted of referring students to monographs or treatises on special branches of the subject, which will not be the least instructive part of his reading. In the botanical list we find no reference even to works so familiar to every student as Mohl "On the Vegetable Cell," Hofmeister "On the Higher Cryptogamia," or the writings of Robert Brown. We venture to say that from the careful study of any one of these works, or even of such smaller treatises as Dr. Hooker's lecture on "Insular Floras," or the introductory essay to his "Flora of Tasmania," the student will gain a deeper insight into the philosophy of his science than from the greater number of the books in the recommended list.

But the greatest defect in the botanical section we take to be the very small stress that appears to be laid on practical work. In accordance with the prominence which is given throughout the whole scheme to histology, it is true that the candidate will be tried with "dissections and descriptions of preparations, illustrating the minute structure and organs of plants;" but he is not informed that his practical acquaintance with morphology and the principles of classification will be tested by requiring him—as is done at all the examinations at the University of London, constituting the most fruitful source of "pluck"—to describe and refer to their natural orders plants presented to him in the room. We the more lament this omission, because it will but have a tendency to confirm the low estimate in which the science of Botany is held even by many biologists, who look upon it as a mere science of terms, leading to no large and comprehensive principles, and susceptible of indefinite "cram." Until Botany is rescued from this degrading position, and teachers learn that it is as much a science of experiment and observation as Animal Physiology or Comparative Anatomy, we shall always have to lament the dearth of

philosophical botanists so remarkably exhibited in this country at the present time; and to hear it spoken of even by biologists with a covert contempt.

We make these comments with no desire to detract from the great work which the Board of Studies for the Natural Science School at Oxford is doing, in attempting to elevate Natural Science to a prestige equal to that of the older studies at our national universities. In this endeavour we wish them heartily all success, and are fully sensible of their earnestness to effect this object. But in order to secure success, it is necessary that any mistakes in the early steps must be freely and candidly pointed out, and that the plan of the campaign must be made as faultless as possible. We know that there are those at Oxford who are fully sensible of the deficiencies in the programme to which we have called attention, and who have fought a losing battle for a more thorough and comprehensive, and at the same time more eclectic, plan. We would encourage those to persevere in their endeavours, believing that they must ultimately prevail, and that from this beginning a scheme of instruction in Natural Science will ultimately arise which will be a model for the whole kingdom.

MOUNTAINEERING IN THE SIERRA NEVADA

Mountaineering in the Sierra Nevada. By Clarence King. (London: Sampson Low, Marston, Low, and Searle, 1872.)

A VERY pleasant admixture of science and personal adventure, from the hand of one who is evidently a sincere lover of nature, and is gifted with considerable descriptive power. Men and manners in the Far West are depicted with much humour; and one chapter, entitled Kaweah's Run, narrating the escape of the author from a couple of brigands who attempted to hunt him down, will show that a Government surveyor's work in America is apt to be more exciting than pleasant. It is a good while since we have read a book so thoroughly unaffected and fresh; redolent of the clear air of those lofty Sierras where (hear it, ye Alpine climbers, who, in your haunts, daily curse Jupiter Pluvius!) fine weather is the rule. The description of some of Mr. King's scrambles is enough to make the Alpine Club rush off in a body to Mount Whitney; but we cannot help suspecting that his neck would have more than once been safer had he known the rules of that fraternity and carried a good *piolet.*

Mr. King does not intend his book for a scientific treatise, but there are some valuable notes scattered up and down its pages, and with these we must chiefly concern ourselves. The first chapter gives a good sketch of the geology and physical geography of the Sierra Nevada district. It was submerged till Jurassic periods, the ocean shallowing much in the later Triassic time. Then were produced the long mountain waves which stretch from Mexico probably into Alaska, reaching as far east as Middle Wyoming, and forming one broad zone of crumpled ridges, whose westernmost and loftiest member is the Sierra Nevada. Rivers carved the land into cañons, and the sea gnawed its western shores during all the Cretaceous and much of the Tertiary period, in the later part of which the coast ranges were rolled up, facing the Sierra Nevada, and converting the California valley into a great inlet of the sea. Then, from newer and older ranges alike, began an epoch of furious volcanic activity, till at last the fires burnt low and the greater number went out altogether. To this succeeded a period when, as in North-Western Europe, great glaciers flowed down the valleys, polishing the rocks and leaving behind them a huge trail of moraine. Now they have shrunk back into snow-fields; and it is only here and there, as about Mount Shasta, that we find any mention of true glaciers in Mr. King's book.

The magnificent cañons, which have more than once been mentioned in the pages of NATURE, are frequently and vividly described. This is the author's opinion of their origin: "Although much is due to this cause (the cutting power of rapid streams) the most impressive passages in the Sierra valleys are actual ruptures of the rock, either the engulfment of masses of great size, as Professor Whitney supposes in explanation of the peculiar form of the Yosemite, or a splitting asunder in yawning cracks. From the summits down half the distance to the plains the cañons are also carved out in broad round curves by glacial action." It may seem presumptuous in one who has never seen the region to differ from Mr. King and his chief, at the same time we cannot help suspecting that here, as in the Alps, it will be shown ultimately that streams have been the principal agents in forming gorges, and that, though they may have been guided by rifts and certainly by joints, no traces of the original fissures can now be found.

Among the scientific "plums" of light description scattered throughout the pudding, we may notice the following:—The granite of some of the mountains of the Yosemite valley exhibits spheroidal structure on a colossal scale, "concentric layers like the peels of an onion each one about two to three feet thick." This structure never descends into the mass for more than a hundred feet. The author notices a peculiar flaky structure on the surface of ice-worn granite (p. 147) developed, as he believes, by the great pressure which it has undergone. A curious case of granite polished by sand friction is also recorded on p. 146, reminding us of the polished basalt on the shore of Fife. Earth pillars in the cañon of the McCloud glacier (Mount Shasta) are described, "from one to seven hundred feet high, each capped with some hard lava boulder which had protected the soft (trachyte) *débris* beneath from weakening." A curious cavern in a lava floor in the same region—roughly tubular in shape and more than half a mile long—doubtless produced, like those in Iceland, by the outburst and escape of the still liquid interior of the hardening stream, is worth notice; as well as the fresh-water deposits of a lake which existed through the Cretaceous and Tertiary periods between the Rocky Mountains and the Blue Mountains of Oregon. Nor must we in conclusion forget the humorous tale of how the author, after being sternly rebuked by the palæontologist of the survey for loving snow-peaks better than fossils, repented and found a cephalopod in the auriferous slates of Mount Bullion, and so determined their age. We note but one desideratum, and that is a map, which we trust will be supplied should the book reach, as we hope it will, another edition.

T. G. BONNEY

HINRICHS' CHEMISTRY

The Elements of Chemistry and Mineralogy, by Gustavus Hinrichs, A.M. (Griggs, Watson, and Day, Davenport, Iowa, U.S.)

THIS is the second volume of Prof. Hinrichs' series of science instruction for schools. In the former volume the elements of Physics were given; this volume contains the elements of Heat, Chemistry, and Mineralogy, and will be followed by a third, called the "Students' Cosmos." The author has thrown himself entirely into the practical method of teaching the physical sciences—the student has first to perform an experiment, and then draw his own deductions from it. In chemistry, perhaps, more than in the other sciences, this system leads to the best results; for on all sides laboratory practice is recognised as essential to its true understanding. If, however, large laboratories and costly apparatus are required, its introduction in our schools cannot become universal. The author has, however, shown in this volume that by excluding special branches, a considerable knowledge of the elementary methods of laboratory practice may be furnished, almost free of charge, by any school to all its pupils. At a time when science instruction in our schools is attracting so much attention, a series of volumes like the present is peculiarly valuable, and thanks are due to Prof. Hinrichs for his bold effort to show how the physical sciences should be taught.

The subject "Heat" occupies two chapters. The first deals with the sources of heat, modes of heating, radiation and induction, thermometry, calorimetry, and fusing and boiling; the second treats of the relation of heat to mechanical work. These are extremely clear and practical; we think better than those which follow. The third chapter is on "Dissociation and Electrolysis." After a few examples of the splitting up of compounds into their elements have been studied, the student is led naturally to the definitions of elementary bodies, of compounds, and mixtures. The next chapter is confined to the elements and compounds, and some of the principles of chemical nomenclature; to this chapter we must certainly take exception, the author has introduced a novel and arbitrary classification of the elements, which, we think, will tend to confuse the student. He groups the elements into nine genera, giving the characteristic properties of each: thus we have the kaloids, analogous to potassium; calcoids, analogous to calcium; cuproids to copper, and so on; under the last head we find classed, copper, silver, gold. We cannot see any reasons for such grouping, for neither in their chemical nor in their physical properties do these three elements correspond.

The author divides chemical substances into monaries, binaries, ternaries, and serials; the monaries are the elements themselves, the binaries the compounds of two elements, the ternaries of three, whilst the serials comprise organic bodies; there is, however, no reason in the author's definitions why the greater number of the serials should not be classed under the ternaries. The term "serials" the author has taken from the fact that numerous organic compounds can be classed together to form series of substances, differing from each other by a definite increment. The next chapter treats of the synthesis of acids and bases, and chapter 6 is devoted to chemical processes. Under the head of "substitution," the quantitative relations of the elements to each other are brought out. We do not think, however, that the difference between the terms "atomic weight" and "equivalent" is by any means sufficiently defined. A considerable space is devoted to the phenomena of double decomposition and to the complex processes, such as fermentation, &c., which concludes the chemical portion of the work. A chapter on mineralogy follows, but on this it will be difficult to give an opinion, as the method the author uses is novel, but, according to his account, quite satisfactory. The book on the whole is most carefully written, so that the student cannot fail in his experiments provided he follows his instructions; these also are so given as to lead to economical and precise methods of working. At the end of the book a number of blank pages are left for the pupil to fill up with his notes of experiments performed, and results obtained, forming quite a new feature in this class of works. The chapter on the "Chemical School Laboratory" we should recommend to the notice of our teachers, as it gives a description of the author's system of teaching, which, we believe, has succeeded extremely satisfactorily in the case of physics, and, we trust, will be equally successful in chemistry.

OUR BOOK SHELF

The Figure of the Earth. By Archdeacon Pratt. (4th Edition. London: Macmillan and Co.)

THIS is the fourth edition of a well-known book, of which we shall unfortunately not now have any more new editions from the hand of its lamented author. The book has grown much since its first edition as a separate work in 1860. The chapter on the attraction of table lands, mountains, oceans, &c., has been much enlarged since the first edition, and also the chapter on the determination of the figure of the earth by geodetic operations. A chapter, most valuable to the student of physical mathematics, is inserted on the determination of the ellipticity of the earth (considered as a body whose surface is one of its own equipotential surfaces) from pendulum experiments, the moon's motion, and the precession of the equinoxes, respectively. The student of this subject must carefully bear in mind that no observations taken exterior to the surface of the earth can throw any light whatsoever on the internal arrangement of its matter, inasmuch as, according to the well-known theorems of Gauss, there are an infinite number of ways in which that matter might be conceived as being arranged so as to produce the same external effect. The observations above noticed, however, are calculated to throw light on the question as to whether the surface may, within the limits of approximation, be considered as a surface of equilibrium.

In fact, it is known that in any event the external effect of the earth may be precisely effected by the distribution in a concentrated form of the whole matter of its interior over its surface.

The important proposition that any function, which does not become infinite within the limits considered, can be expanded in a series of Laplace's functions, is proved by Mr. Pratt in the text by rather a long method, in order to get over a certain apparent objection as to discontinuity. The following proof of that proposition seems short, and not open to objection.

Let A and B be two points on a sphere of centre O. Let the co-ordinates of any point R referred to A be p and q, where p is the cosine of the angle between $O R$ and $O A$,

and q the angle between the plane $A\,O\,R$ and a fixed plane. Let μ, ω, be similar co-ordinates of R referred to B, and let μ', ω', be the values which μ and ω assume at the point A. Let $F\,(\mu'\,\omega')$ be a function of μ' and ω', which, when μ' and ω' become μ and ω, may be written $F\,(\mu, \omega)$. If $\delta\,S$ be an element of the surface of the sphere, whose radius we shall take as unity, then $\delta\,S$ may be expressed by $-\,\delta\,p\,.\,\delta\,q$, or by $-\,\delta\,\mu\,.\,\delta\,\omega$, according as occasion requires.

It is obvious from spherical trigonometry that

$$p = \mu\,\mu' + \sqrt{1-\mu^2}\,\sqrt{1-\mu'^2}\,\cos(\omega-\omega')$$

and that therefore in the expansion

$$\frac{1}{(1+x^2-2\,x\,p)^{\frac{1}{2}}} = 1 + P_1\,x + P_2\,x^2 + \ldots$$

The quantities P_1, P_2 &c., satisfy Laplace's equations in μ and ω, and also in μ' and ω'.

Differentiating this equality, multiplying by $2\,x$, and adding, we get

$$\frac{1-x^2}{(1+x^2-2\,x\,p)^{\frac{3}{2}}} = 1 + 3\,P_1\,x + 5\,P_2\,x^2 + \ldots + (2n+1)\,P_n\,x^n +$$

Integrating each side of this equation over the whole surface of the sphere, and equating the results, we have

$$\int_0^{2\pi}\int_{-1}^{+1}\frac{1-x^2}{(1+x^2-2\,x\,p)^{\frac{3}{2}}}\,dp\,dq =$$
$$\int_0^{2\pi}\int_{-1}^{+1}(1 + 3\,P_1\,x + 5\,P_2\,x^2 + \ldots)\,d\mu\,d\omega$$

The first of these two integrals is readily found to be equal to $4\,\pi$, being thus independent of x.

$$\therefore \int_0^{2\pi}\int_{-1}^{+1}(1 + 3\,P_1\,x + 5\,P_2\,x^2 + \ldots)\,d\mu\,d\omega = 4\,\pi$$

Now as x approaches unity, every term in the series whose limit is represented by the integral

$$\int_0^{2\pi}\int_{-1}^{+1}\frac{1-x^2}{(1+x^2-2\,x\,p)^{\frac{3}{2}}}\,dp\,dq$$

becomes more nearly equal to zero, except the terms in the immediate vicinity of the value $p = 1$, which increase in value, *i.e.* in the neighbourhood of the point A. Hence, as we diminish x, the ratio of

$$\int_0^{2\pi}\int_{-1}^{+1} F\,(\mu\,\omega)\left\{1 + 3\,P_1 + 5\,P_2\,x^2 + \ldots\right\}d\mu\,d\omega \text{ to}$$
$$F\,(\mu'\,\omega')\int_0^{2\pi}\int_{-1}^{+1}\left\{1 + 3\,P_1\,x + 5\,P_2\,x^2 + \ldots\right\}d\mu\,d\omega$$

that is to $4\,\pi\,.\,F\,(\mu'\,\omega')$ becomes continually more nearly a ratio of equality, since $F(\mu'\,\omega')$ is the value towards which $F\,(\mu\,\omega)$ continually approximates as we draw nearer to the point A. Hence we have in the limit

$$4\pi.\,F\,(\mu'\,\omega') = \int_0^{2\pi}\int_{-1}^{+1} F\,(\mu\,\omega)\,(1 + P_1 + 5\,P_2 + \ldots)\,d\mu\,d\omega$$

and since P_n satisfies Laplace's equation of the nth order in $\mu'\,\omega'$

$$\therefore \int_0^{2\pi}\int_{-1}^{+1} F\,(\mu\,\omega)\,P_n\,d\mu\,d\omega$$

also satisfies it, because $\mu'\,\omega'$ are constants so far as this integration is concerned. Hence $F\,(\mu'\,\omega')$ is expanded in a series of functions satisfying Laplace's equations.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Volcanoes of Central France

THE eruptions of A.D. 458-460, whose showers of pumice or ashes reached and alarmed the city of Vienne, then the capit a of the chief State in Gaul, and led to the institution of the Rogations (now called Litany) and the "Rogation Days," cannot have proceeded from the province of Auvergne, as Mr. Green supposes (NATURE, May 16). That province, containing about half the French volcanoes, is the most distant of the three volcanic ones from Vienne, and moreover is held to have been quiescent in that age (as well as ever since); because the eminent writer, Sidonius Apollinaris, who had settled there, and wrote a poem on its scenery, betrays no knowledge of its volcanic phenomena. So, at least, Sir Charles Lyell has repeatedly insisted. It is true that, writing before the date of the Vienne calamities, his silence proves nothing; but as fully half the French craters are not in the Auvergne, but between that province and Vienne, namely, in either the Velay or Vivarais, within about fifty miles of that city, and ranged along almost a quadrant (the S.W. quadrant) of its horizon, there can be little doubt that some of them were the scene of the "portentous fires," and sources of the "Sodomitic showers" that alarmed the Burgundian capital, and led St. Mamertus to institute these fasts. Of Mamertus himself there remain no writings, and the memory of any historic eruptions in France appears to have died out from that very century to the present; though none in all history were better attested, none within many centuries of Pliny's even so well. For it is strange that no later chroniclers mention anything but the earthquakes and some fires of buildings; the sole authorities for the eruptions being their contemporaries, the above Sidonius and the bishop who succeeded Mamertus in his see, and these two being the sole men in Gaul of that generation whereof any document remains. The former writes to Mamertus himself a very fulsome, adulatory, but necessarily a materially true memoir of the facts; and the latter allusively recounts them in a sermon to the very flock among whom the observances had begun. It seems impossible to conceive better witnesses to any event whatever, and they are literally all the contemporary writers extant.

The late Sir Francis Palgrave appears the first modern to have disinterred this page of forgotten history, in the *Quarterly Review* of October 1844. See also a most extraordinary paper on it in the *Gentleman's Magazine* of May 1865, commented on by me in the *Reader* of the next month (p. 683). As the original passages, however, of Sidonius and Bishop Avitus have not been reproduced, I enclose literal translations of them, if you think they would interest your readers. The style of their time must be allowed to be detestable, but not quite without parallels.

E. L. GARBETT

"Sidonius to Lord Patriarch Mamertus, health! It is reported the Goths have advanced their camps on to Roman soil! To this kind of eruption we wretched Auvergnats are always the gate. For we afford to the enemies' malice peculiar satisfaction; because, as they have not yet marked their bounds from Ocean to Rhone by the course of the Loire, they (under Christ's mercy) find their sole hindrance from our opposition only. Indeed, the tracts and regions of the surrounding country the eager assault of their threatening power would long ago have devoured. But in this, our so bold and dangerous a resolution, we trust not in our hearts either to the crumbling face of ramparts, the rotten barrier care (*studium*), or the failing defence of sentinels for assistance, but are only soothed by the comfort of the Rogations introduced, of which you were the author; which, being to be founded and instituted, the Auvergne people has begun to practise, if not with equal result, certainly with not inferior zeal, and on this account does not turn its back to the surrounding terrors. For it does not escape our research (*latet nostram sciscitationem*) how, in the first times of these supplications being instituted, by the terrors of what manner of prodigies the city divinely committed to you was being emptied. For at one time the walls of the public fortifications were shaken down by the continual earthquakes; at another the fires, often attended with flame, were smothering (*tumulabant*) the frail roofs with a load of showered ashes (*superjecto favillarum monte*). Now the vast lairs (*stupenda cubitia*) in the forum harboured the boldness (O portentous tameness!) (*pavenda mansuetudo!*) of deer. When you, amid that flight of the nobles and the common people, the state of the city being desperate, quickly had recourse to new imitations of the ancient Ninevites, lest your despair, too, should mock the divine admonition. And truly at that time you could the least distrust God without sin, after your experience of his mercies. For once, when a certain city had begun to blaze, your faith had glowed more than the fire," &c. (He proceeds to relate the extinction of a former conflagration by the prayers of Mamertus; but this

and the remainder of the letter, though translated by Colenso to throw ridicule on the people's religion, has evidently no bearing on the calamities and portents of A.D. 458-60, but refers to an earlier event.)—*Epistles of Sidonius Apollinaris.* Book vii. Ep. I. (From Migne's *Patrologia,* tom. 57, p. 563.)

"There pervades, indeed, the vital way (or faith) not through the lands of Gaul only, but almost the whole world, the fertilising stream of these Rogation Day observances, and cleanses the earth infected with vices by the wholesome flux of an annual expiation. More special reason, however, have we in this same institution for service and rejoicing, because from hence in a manner it flowed for the benefit of all. From our source at the first it spread; and perhaps even (we may say) it pertains to some dignity or privilege, the first beginning of such an institution. At any rate, when an ineffable distress (*necessitas*) tamed down the proud hearts of our Viennese to this manner of humiliation, our Church, perceiving the cause of her chastisement (*ægritudinis*), caught to herself not as chiefly before all others, but as alone among all, feeling the need there was for the present observance to be instituted, far more eagerly a remedy than a primacy (or precedence). And, indeed, the causes of the terrors of that time, I know that many of us recollect well (*recolere*). For truly the repeated fires, the frequent earthquakes, the mighty noises, threatened to add to such a cremation (*cuidam funeri*) of a whole world some equally prodigious entombment (*bustuale*). For in the populous haunts of men the tame appearance of the beasts of the forests was observed; God knows whether deluding our eyes or driven there by the portents. But whichever of these two it might be, it was perceived to be alike monstrous, whether thus in reality the wild natures of the beasts were tamed, or whether so frightfully in the views of the spectators phantoms of false visions could be formed. Amid these things various were the notions of the populace, and divers the opinions of different classes. Some, concealing what they felt, ascribed to chance what they would not allow to (be matter of) weeping. Others, of healthier mind, discovered truly the new iniquities (*abominabilia*) aptly agreeing to the natures and significance of the ills. For who, in the oft-seen fires, would not dread Sodomitic showers? Who, in the shaking elements, would not believe either falls of roofs (*culminum*) or openings of the earth to be at hand? Who, when seeing, or certainly thinking he saw, the naturally timid deer advancing through the straits of doorways, even to the sides (colonnades) of the forum (*ad fori latera*), would not presage an impending doom of desolation?" (He then recurs, like Sidonius, to the story of the earlier conflagration of a palace or town hall, arrested by Mamertus, which leads to the confusion of these two calamities by all later chroniclers, and loss of memory of the eruptions, and showers of favillæ)—*Homily of Avitus concerning Rogations.* "*How the Custom of the Rogations arose.*" (*Migne Patrologia, tom.* 59. *p.* 289.)

SOME years ago my attention was especially directed to the date of the latest eruptions in Auvergne, as usually supposed to be indicated by the appointment of the Rogation Days, A.D. 469, by Mamertus (rather than Mamercus), Bishop of Vienne. A reference to original authorities convinced me that there is no satisfactory evidence of anything beyond long-continued earthquakes of such severity as to drive the wealthier part of the population out of the city, and, as it would seem, the wild beasts into it. Much is said about fire, but the rhetorical and inflated expressions of those living nearest to the event may be applied to either volcanic or domestic conflagration; and there is great reason to believe that the latter only was intended, in the apparent absence of volcanic foci in the neighbourhood. These, according to Scrope's map, all lie at a considerable distance (if I recollect aright, twenty or thirty miles); and though it is of course possible that the site of some nearer outburst may have been hitherto unnoticed, the expressions used hardly warrant the trouble of any laborious search for it. Should any of the residents in the neighbourhood of Vienne be conversant with geology, they would be able to furnish decisive evidence on the subject. The original story is a curious one, but it has not lost in the telling.

Hardwick Vicarage, May 25 T. W. WEBB

The Approaching Transit of Venus

IN NATURE of the 4th of January last Mr. J. Carpenter gives an interesting sketch of the arrangements in progress for observing the forthcoming Transit of Venus. He states that French and German astronomers have decided on establishing a station of observation at Muscat (Mascate) or at some place between that nasty little port and Teheran. Now, as a point along this line is considered so favourable by Continental astsonomers, will you allow me through your pages to call Mr. Airy's attention to the peculiar advantages of Jask in this respect. Cape Jask, on the Mekran Coast, is situated, roughly, in lat. $25\frac{1}{2}$ N. and long. $57\frac{1}{2}$ E. We have here a large and intelligent English telegraph staff, and work a double line of telegraphs to Europe. We have three large stone-built bungalows (houses) with strong, flat, cement-covered roofs, which are approached by spacious staircases. The large bungalow, forming the clerks' quarters, is about 250 feet long, 20 high, and 40 broad. It is divided in the centre by a sort of tower, in which are situated the stairs leading to the roof. The latter would be a most convenient place for erecting the astronomical instruments, &c. There is no telegraphic communication with Muscat, and it is about two days' sail, with a fair wind, from Jask, which is the nearest telegraph station. Should the Astronomer Royal decide on sending out a couple of observers here, I promise them a hospitable reception and every assistance. The fortnightly mail steamers between Bombay and Bussorah, pass within fifteen or twenty miles of this place, and could be easily induced by Government to call in and land the party.

Mr. Latimer Clark, who visited this station towards the end of 1869, will, I daresay, if called upon, be able to give some further particulars, and can vouch for the accuracy of my statements.

Persian Gulf Telegraph Dept., Jask Station

Recent Climatic Changes

MR. HOWORTH's letter on "Recent Climatic Changes" in NATURE of the 9th May, is most instructive and interesting, more especially to those who have visited the Arctic Sea; but on one point I must venture to differ from him, that is, when he expresses his belief that the Esquimaux migrated from the northward in consequence of the increasing rigour of the climate in high northern latitudes.

I have seen the Esquimaux at the mouths of the MacKenzie and Coppermine Rivers and at Repulse Bay in longitudes 135°, 115°, and 87° West, respectively. At all these places I found their traditionary belief to be, that they came originally from the west, across a narrow sea (probably Behring Strait), followed the coast line eastward, then southward along the west side of Hudson's Bay; some of them making their way to the east coast of that great bay and to Labrador by crossing the comparatively narrow channels separating these places from Southampton, Mansfield, and other islands, at the entrance of Hudson's Bay.

As Victoria and Wollaston lands, and other places still farther north, were probably at that time (as some of them are at present) well stocked with game, part of these people in their eastward drifting would naturally turn to the northeastward, until they reached North Lincoln and Ellesmere lands in lat. 77° or 78° North, from which they probably crossed Smith Sound to Greenland, along the west shore of which they would then have gradually spread southward.

Thus the Skrellings who destroyed the Norse colonists of South Greenland, came, as Mr. Howorth says, from the north. Indeed, they could not have come from any other direction, except by making a long sea voyage, for which their frail craft (if they had any canoes at that time) were by no means well fitted.

That the "Saga" writers knew that Esquimaux were to be found in Labrador before they were seen in Greenland, goes far, I think, to support the view I have expressed; because, if coming from the west, they could much more easily and speedily reach Labrador than the southern parts of Greenland; whereas had they come originally from the north, the facilities for arriving at these places would have been reversed.

I have been told by one of the greatest authorities, perhaps the very highest, on such subjects, that it is not likely that the Esquimaux originally came from Asia, as the form of their heads differs most materially from that of the heads of those Asiatics whom in other respects they most resemble.

This seems almost an unanswerable fact or argument against the correctness of the tradition of the Esquimaux, and the theory I have advanced, which very likely may have no novelty in it.

In opposition to this very strong fact, may I suggest the possi-

bility that the change in the mode of life of the Esquimaux in their new country (to which they were probably forcibly driven), and a change in the manner of carrying the child in infancy, may have caused a material alteration in the form of the head, whilst other peculiarities of face and form remained nearly the same.

The Esquimaux infant is carried in the hood of the mother's coat, and its head is perfectly free, with no pressure on one part more than another.

The peculiar form of head of the Red Indian of America may in a greater or less degree be caused by the kind of cradle used. The baby is fastened in its cradle in such a manner that the whole weight of the little creature's head rests almost constantly on the back part or occiput: the effect would be to reduce the longitudinal and increase the lateral diameter of the skull.

Of course I do not allude to the intentional and artificial alteration of the form of the skull, as practised among the Chenooks.

The discovery of many reindeer and muskcattle by the Swedish (? German) expedition on the East Coast of Greenland, as mentioned by Mr. Howorth, where previously none had been seen, may be accounted for by these animals—after having been much hunted and harassed by the natives near Smith's Sound and Melville Bay, on the north-west extremity of Greenland—migrating to the east shore, where, finding food and rest, they remained unmolested to increase and multiply, which they do very rapidly under such conditions.

Deer, muskcattle, and hares were found in great numbers, and very tame and in good condition on the Parry Islands, in latitude 76°, and on Banks Land in latitude 74° N., by several of the recent Arctic expeditions, and these do not appear to have migrated southward in the autumn. I have no doubt that were those localities visited by a band of hunters, these animals would after a few years become shy and timid, and finally move off to a more safe position, either north or south, as their own instinct or the trending or nature of the country might lead them. This I have known to occur frequently in America farther to the south.

These sudden and unforeseen migrations (being an exception to the usually very regular habits of the animals) are among the chief causes of the suffering and deaths by starvation among the Esquimaux.

Although what I have written above has been the result of my own observation, it may have been spoken or written by some one else before, much better than I can pretend to do. If so this communication will find its way, as it deserves, to the waste-basket.

JOHN RAE

A Scientific "Bone-Setter"

THE interesting article on "Bone-Setting" in NATURE for May 9 induces me to narrate my own experience. More than twenty years ago, in the city of New York, while swinging upon parallel bars in the gymnasium, I fell backwards, and to save my head threw out my left arm, thus catching the fall upon the palmer end of the radius, and, as it proved, fracturing the neck of the radius at the point of articulation with the ulna. I sent for one of the most eminent surgeons, then Professor and surgeon to a large hospital, but several hours elapsed before his arrival; and by that time the swelling and inflammation at the elbow had all the appearance of a sprain, and the fracture was not detected. Some days afterwards the surgeon discovered that there had been a fracture, and that a false adhesion had begun. This was broken up, and the arm set in splints, according to the approved method. After the usual time the bandages were removed, but the forearm was incapable of flexion, extension, or rotation. Every appliance was used to restore it to its normal condition, such as lifting, friction, sponging, &c., but without effect. The arm became useless, and began to shrivel. It was examined by the first surgeons of New York and other cities. Some thought that the radius had adhered to the ulna, others that there was a deposit of interosseous matter, but none could suggest a remedy.

Nine months after the accident I chanced to be in Philadelphia, and called upon Dr. Rhea Barton, who, though he had retired from practice, consented to look into my case. After careful examination, he said, "If you will consent to suffer the pain (it was before the use of chloroform) I will agree to restore the arm." He went on to say that pressure demonstrated a slight crepitation at the joint, and also a slight elasticity; and this assured him that the trouble was in the ligaments; that in consequence of the long imprisonment of the arm in splints, while under inflammation, a ligamentous adhesion had taken place, and the synovial fluid had been absorbed. He then applied one hand firmly to the elbow and the other to the palmer extremity of the radius, and, diverting my attention by anecdote and wit, thus relaxing the resistance of the will to pain, he gave a sudden wrench, there was a sound like the ripping of cotton cloth, and the arm lay outstretched before me, quivering with pain, but capable of motion. Mechanical appliances for a few weeks so far completed the restoration that I have ever since had about four-fifths of its normal use and power.

Now, Dr. Barton did, upon scientific knowledge, what the "bone-setter" does empirically—"by manipulation, suddenly and forcibly tearing asunder the adhesions" formed between the ligaments and the bone; and he assured me that the whole difficulty would have been averted had the arm, when under treatment for fracture, been gently moved at times according to nature. I think he has published a monograph upon this point, but I cannot now refer to it.

JOSEPH P. THOMPSON

Berlin, May 22

Pathological Legends

MR. TYLOR speaks of vampires as illustrations of Savage Animism, and regards them as inventions to explain wasting disease. The records of such unseen agents point to two classes of vampires, one of which has nothing to do with wasting disease. To take two extreme cases: the story of Grettir's conflict with Glam the house churl, contrasts with the Vampire Cat of Nabeshimes, as told by Mitford in the "Tales of Old Japan." The Northern hero seeks the evil one and overpowers him, but his success is dearly bought, for evil temper and nervousness never leave him, and his after life is unlucky from these two causes. The Japanese Prince is visited nightly by the counterfeit of his lovely concubine, he pines away, and is only saved by the energy of a retainer, who slays the fair persecutor. Here are types of two kinds of malady; one is truly wasting, the other is of that kind which ends in apoplexy, epilepsy, acute mania, or if death is not speedy and sudden, dyspepsia may reduce the hero to Grettir's state without obviously impairing his strength. The Japanese story gives the common superstition among polygamous people with whom progressive exhaustion is not uncommon, as "Hawke's Voyages" quaintly explain. The Grettir Saga gives a pagan version of what figures more than once in Christian legends as saintly intervention. Thus, the Scandinavian invader blasphemes the English saint, who straightway appears to him, and points the finger; the blasphemer drops down dead. Glam, the churl, gorges himself with food, and goes to the hill, the next morning he is found crushed and distorted, and the horror of his punishment is proportioned to his crime, for he ate meat on a Church fast, and it was doubtless sweet to his neighbours to recall the fact that they heard his shrieks when sitting in church. Glam's successors perish violently, one of them being found convulsed and broken on Glam's cairn, just as 'in more places than one in Scotland men have been found in convulsions near places which superstition had made terrible on account of some great crime. But Grettir, for twenty years after his fight with Glam, leads a life of incessant fighting as an outlaw. He cannot go alone, his nerve is shaken, he sees things in the dark, and his temper is irritable. It is of course impossible to separate out the various forms of unseeen agency to which men in rude times were subject. But the Vampires of the North and Incubi are members of the same family; the Vampires of Asia belong to another family. The former represent indigestion, the results of gross overeating and drinking, aggravated, doubtless, by the circumstances that the opportunities of excess were not frequent, and that semi-starvations occurred often between copious meals. The demons are mostly men; in all cases they give rise to violent conflicts, in which, if a man dies, his distorted convulsed body suggests the presence of a corporeal enemy, a reasonable enough notion among those to whom natural death meant, in the case of a strong man, death by the sword. The latter represents the results of lechery in some form or other; there is no tale of conflict, though now and then sudden death is accompanied by convulsions such as, we know, frequently terminate cases of general paralysis and *Tabes dorsalis*. The correspondence between the Northern Berserker and the furious Malay who runs amuck, is interesting in reference to this contrast. The insanity of the Berserker is that of an individual; the persecution of the Northern vampire falls on the whole family of the sufferer; and, while it is difficult under ordinary circumstances for any large number of people to become simultaneously affected by genuine

fury (though Mr. Wallace furnishes a possible analogy to ancient custom in what we may call a sociable Amok), the contagion of fear makes it easily intelligible how even a district might come to see and hear what had no existence save in the disturbed imagination of one. The Incubi and Suscubi of the Middle Ages in Europe may be paralleled at the present day in asylums, and, now as then, are met with among those who have placed themselves in conditions similar to the unhealthy ones of the Convent.

In reading over the confessions of the witches in England and Scotland, it is strange to find how exactly the language employed expresses the frequently described sensations of women labouring under uterine and ovarian disease. Doubtless, not all thus suffered; but the confusion once made and heard would be repeated by the unhappy imbeciles from whom chiefly the witch ranks were recruited. JOHN YOUNG

Glasgow University

The Vervain and Yellow Fever

ALLOW me to say a few words on the report of the English Vice-Consul at Ciudad, Bolivar, concerning the efficacy of the Vervain plant as a remedy for yellow fever and black vomit (NATURE, March 21, p. 412). The plant in question is *Stachytarpha jamaicensis*, Vahl, a very common and rather troublesome weed, called in Spanish America "Verbena," in the British West Indies "Vervain," and in the Brazils "Gervaõ." Its medicinal properties have been greatly exaggerated, though it is certainly somewhat aromatic and astringent; but in yellow fever and black vomit its efficacy is next to nothing. For a good description of the plant and some notes on its supposed and real virtues, I refer to Auguste de St. Hilaire, "Plantes usuelles du Brésil," plate 39 (Paris, 1824). Another tolerably good figure is given by Sloane, "The Natural History of Jamaica," plate 107, 1, who mentions several diseases against which it was used in his times (and probably still), stating finally, that "it is good against charms." A. ERNST

Caracas, Venezuela, May 6

ELECTRIC VALENTINE

TELEGRAPH CLERK ♂ TO TELEGRAPH CLERK ♀

"THE tendrils of my soul are twined
With thine, though many a mile apart;
And thine in close-coiled circuits wind
Around the magnet of my heart.

"Constant as Daniell, strong as Grove;
Seething through all its depths, like Smee;
My heart pours forth its tide of love,
And all its circuits close in thee.

"O tell me, when along the line
From my full heart the message flows,
What currents are induced in thine?
One click from thee will end my woes."

Through many an Ohm the Weber flew,
And clicked this answer back to me—
"*I am thy Farad, staunch and true,*
Charged to a Volt with love for thee."

$\frac{dp}{dt}$

[NOTE BY THE EDITOR—

Ohm = Standard of resistance.
Weber = Electric current.
Volt = Electromotive force.
Farad = Capacity (of a condenser).

$$\text{Velocity of Puck, } \frac{\text{Once round the Earth}}{\text{40 minutes.}}$$

$\therefore$ 1 Ohm = 600 Pucks.]

NATURAL SCIENCE AT OXFORD

IT has been resolved in Convocation that the Curators of the University Chest be authorised to pay to the credit of the Museum Delegates the sum of 1,000*l.*, to be employed at their discretion for the maintenance and improvement of the Collections in the Museum; a full statement of the expenditure for these purposes being prepared annually and reported to Convocation.

MAGDALEN COLLEGE.—*Demyships and Exhibition.*—There will be an election at this College in October next to not less than Six Demyships and One Exhibition. Of the Demyships, one at least will be Mathematical, one at least in Natural Science, and the rest Classical. The Exhibition will be in Mathematics, is of the value of 75*l.* per annum, inclusive of all allowances, and is tenable for five years.

EXETER COLLEGE.—There will be an Election to a Natural Science Fellowship in this College on Wednesday, June 10. The Examination will be in Biology. The Fellow elected will be required to reside and take part in the instruction of the College. The election will take place under the conditions of the following special ordinance of the College:—"Any Fellow who shall be elected previous to June 1874, with the declared purpose of taking part as Tutor or Lecturer in the College, shall *ipso facto* vacate his Fellowship on ceasing to reside. Provided also that if the said Fellow shall have taken part as Tutor or Lecturer in the College for seven academic years, consecutively or not, or for part of the time in one office and part in the other, he shall retain his Fellowship, subject only to the other causes of avoidance of Fellowship. Any fellow so elected shall hold himself bound, on pain of the loss of his Fellowship, to take part, if required, as Tutor or Lecturer in the College. If any such Fellow be incapacitated through ill health for educational work in the College, it shall be competent for two-thirds of the Governing Body, with the sanction of the Visitor, to dispense with the required residence during the continuance of such ill health." The Fellow elected under the ordinance will be subject in all other respects to the Statutes of the College. The Examination will begin on Tuesday, June 11, and no person can be admitted as a Candidate who has not passed all the Examinations necessary for the degree of Bachelor of Arts in the University of Oxford, or been incorporated as a graduate in the University.

SECOND PUBLIC EXAMINATION.—*Pass School.*—In pursuance of the statute, the Board of Studies for directing the Examination of Candidates who do not seek Honours at the Second Public Examination, and also the Examination in the Rudiments of Faith and Religion, gives notice that the books and subjects which may be offered in the Easter and Trinity Terms 1874, and until further notice, are—

In Group C.—(1) The Elements of Plane Geometry, including the doctrine of similar triangles. This includes the portion of Geometry treated of in Euclid Books I.-IV., with the definitions of Book V., and such parts of Book VI. as treat of similar triangles. These subjects may be read in any other treatise. The Elements of Trigonometry, including the trigonometrical ratios of the sum of two angles, the solution of plane triangles, the use of logarithms, and the mensuration of plane rectilinear figures. (2.) The Elements of the Mechanics of Solid and Fluid Bodies, including the composition and resolution of forces, centre of gravity, the simple machines and the application of virtual velocities to them, the laws of motion, the laws of falling bodies, the motion of projectiles, the pressure of fluids on surfaces, the equilibrium of floating bodies exclusive of the theory of stability, the methods of determining specific gravities, the laws of elastic fluids, simple hydrostatical and pneumatical machines. (3.) The Elements of Chemistry, with an elementary practical examination. Candidates who intend to offer this

subject for examination are recommended to read that part of Roscoe's "Lessons in Elementary Chemistry" which treats of Inorganic Chemistry (pp. 1-268, new edition, 1869). The practical examination will be in the following subjects as treated of in Harcourt and Madan's "Exercises in Practical Chemistry":—1. The preparation and examination of gases (pp. 59-107); 2. The qualitative analysis of single substances (pp. 247-300; see also sections IV. and V., omitting that which relates to substances or properties of substances not referred to in the Analytical Course). (4.) The Elements of Physics. Candidates offering themselves for examination in this subject will be expected to show an acquaintance with Part I., together with any two of Parts II., III., IV. of the following treatise;—"Elementary Treatise on Natural Philosophy," by Deschanel. Translated and edited by Prof. Everett. Part I. Mechanics, Hydrostatics, and Pneumatics. Part II. Heat. Part III. Electricity and Magnetism, of which chapter 39 may be omitted. Part IV. Light and Sound (which will be published in a few weeks(.

THE MURCHISON CHAIR OF GEOLOGY

UPWARDS of a year ago we duly chronicled the founding of a chair of geology and mineralogy in the University of Edinburgh by Sir Roderick Murchison, and we augured that the munificence of the founder would not be long in bearing fruit. It is pleasant to learn that the first session has been concluded successfully, and that the class has been greatly larger than the most sanguine friends of geology in Scotland had anticipated. In addition to the ordinary lectures of the class-room, there have been frequent afternoon excursions to the field, where the principles of the science have been learnt in a way in which they cannot be from mere lectures or books. Edinburgh is peculiarly favoured by nature for instruction of this practical kind. The crags and ravines which surround, or even stand in the midst of, the streets and gardens furnish admirable models of many of the more important and striking facts of physical geology. These advantages have been fully made use of during the past winter and spring. There has been, we are told, a brisk sale of geological hammers, and bands of hammerers have been seen on Saturday afternoons wandering over hill-side and quarry. At the close of the session Prof. Geikie and his students celebrated the termination of their labours together by a week's holiday in the island of Arran. For such an excursion good weather is the first grand essential, and in this respect the party appears to have been singularly lucky. The days were bright and bracing, so that from the highest hill tops the eye could wander over all the wide expanse of firth and fell which lies between the mountains of Jura and the far-off faintly-seen uplands of Galloway.

It was chiefly to the northern half of the island that the attention of the excursionists was devoted. They traced, of course, the well-known and often-described features—the granite mountains and veins, the schists, the trap-dykes, the carboniferous sandstones, conglomerates, limestones and tuffs, the raised beaches, &c. But they noted some points which deserve, perhaps, more special remark than has yet been accorded to them, and of these we have been furnished with the following jottings:—

1. Some interesting observations were made on the relation between the joints of the granite and the forms of surface into which that rock has been wasted. Everybody who has seen the Arran mountains remembers their sharp serrated ridges and deep corries. It was noticed in all the examples which were visited that each knife-edged crest coincided with the intersection of two sets of joints dipping in opposite directions, as the ridge of a roof coincides with the line along which the two opposite slopes meet. Where the one set of joints differed most in angle of inclination from the other, there was seen to be a corresponding difference in the slope on two sides of the crest, the highly inclined joints having a steep face, sometimes quite a precipice, on their side, while the less inclined joints had a gentler declivity on the other. From the summits it seemed as if the changes in the direction and inclination of the granite ridges were largely due to changes in the trend and slope of the systems of cross-joints. But there was not time to work out this problem.

2. Some mineralogical and petrographical facts of interest were gleaned. The passage of the Arran pitchstone was traced into a dull pearlstone which appeared to be closely connected with, if, indeed, it did not pass into one of the pale compact felstones or "compact felspars." The common association of pitchstone with the tertiary volcanic rocks of the west coast, and its entire absence from any of the abundant palæozoic volcanic masses of the mainland, raises the suspicion that perhaps the Arran pitchstones are likewise of tertiary date. The association of these pitchstones with some of the characteristic felstones or porphyries of that island also suggests as late an origin for the latter. Some facts, indeed, were noted, which, if properly worked out, might throw light on this question. It was observed, for example, that in the picturesque columnar ridge above Corriegills the columns are so arranged as to indicate that the mass of rock flowed along and consolidated in a trough or hollow. Was this hollow a valley carved out of the denuded surface of the carboniferous rocks, and did the porphyry flow into it as a *coulée?* A phenomenon of rare occurrence was noted in this Corriegills porphyry. Usually the quartz in such rocks exists merely as irregularly-shaped blebs or grains. In this rock, however, it is crystallised, and frequently appears in little doubly-terminated pyramids. Some of the party spent half an hour in gathering up perfect crystals from the weathered hollows of the rock. These crystals do not occur in amygdaloidal cavities but as essential constituents of the rock. In the Goatfell granite some cavities were found with well crystallised quartz, and one of the party was fortunate enough to light upon one cavity from which he obtained a handful of small cairngorms.

3. The moraines of the Glen Cloy afforded a pleasant afternoon. It was matter for surprise to some of the party that amid all that has been written about Arran these truly remarkable moraines have not received more notice. It is true, they do not lie among the group of the higher mountains of the island, and they have not the magnificent setting around them which they would have had if they had stood in Glen Rosa, or Glen Sannox, or Glen Iorsa. But in none of these glens, even though they plunge into the very heart of the central mass of granite, is there anything in the way of moraines at all to compare with the huge concentric mounds of rock-rubbish, cumbered with blocks, which roughen the bottom and sides of the deep recess in which the upper part of Glen Cloy terminates. The plateau which served as the snow-field whence the Glen Cloy glacier was fed rises to an average height of only about 1,400 or 1,500 feet above the sea, while the neighbouring granite peaks are about twice as high. Yet the higher granite mountains have afforded comparatively few and small moraines. It gives a good notion of the severity of the climate during the glacial period to reflect that the little isolated patch of elevated ground, forming now the island of Arran, was large enough to nourish, even on its lower plateaux, snow-fields and glaciers.

4. Many striking lessons were learnt regarding some of the broad aspects of atmospheric denudation. Particularly were these lessons brought home to the mind among the wasted crags and corries of the granite mountains. Granite which, in the popular creed, is regarded as one of the most imperishable of rocks, was seen to be covered

with acre upon acre of its own wasted *débris*. On the crests of the heights the rock was found to be split by frosts along its joints; numberless blocks had fallen off, and the slopes below were thickly strewn with them. On smoother declivities, such as those that descend from the lonely and barren Beinn Bharrain, each casual torrent was seen to have ploughed out of the loosened and corroded granite a deep trench, which in time might get widened and deepened into a lateral valley. The waste of mountains could not be more eloquently revealed. As the party in long file threaded its way through these solitudes, a feeling which had been growing all day found at last expression, and as the scattered scouts who, in the exuberance of young life, had dispersed up and down hill on either side of the main body, gathered together into one merry company at the edge of the dark and lonely Corrie au Lachan, it was unanimously agreed that had this band of stone-breakers seen nothing more than these proofs of how a mountain may be sculptured, the lesson was worth all the trouble and fatigue of the excursion.

NOË'S THERMO-ELECTRIC BATTERY

A SUPPLY of dynamic electricity is almost as requisite now for the lecture table as the supply of gas or water. The decomposition of water and various other liquids, the decomposition of certain gases in Hoffmann's U tube, with the aid of Rhumkorff's coil, and the physical test afforded by the passage of electricity through vacua containing traces of different gases, are most constant lecture experiments. And no wonder: the brilliant purple light afforded by the passage of electricity through a nitrogen vacuum, is, perhaps, the best and most reliable, if, indeed, it be not the only, test for nitrogen gas; while the decomposition of water gas, of ammonia, and of marsh gas, are experiments of the utmost importance in modern Chemistry. Hitherto the chief drawback has been the voltaic battery; the setting up of the battery before the lecture, the taking it to pieces afterwards, the constant amalgamation of the zinc plates, the consumption of zinc and acid, the fumes—in a word, the general inconvenience inseparable from any form of voltaic battery, but reduced to a minimum in Sir William Thomson's constant gravitation battery. The former of these inconveniences are more apparent, when, as is often the case, the battery is only required for five minutes during the whole lecture.

Hence, when a statement recently appeared in Poggendorff's "Annalen," to the effect that a thermo-electric battery of great power had recently been constructed in Vienna by Franz Noë, we were glad to take the first opportunity of trying to what extent it could replace the ordinary voltaic battery for the lecture table. It was stated that the battery could readily decompose water, work a Rhumkorff's coil, and powerfully excite electro-magnets. As we understand from the maker that the battery about to be described is the only one in use in this country, it may be of interest to give a short account of its capabilities.

The battery consists of eighty elements, which are heated by eighty small Bunsen burners, the cooling of the opposite extremities being effected by broad, blackened sheets of copper, which of course radiate freely. The negative metal is a silver-white alloy drawn into wire, and partially enclosed in small copper cylinders to protect it from the direct action of the flame. The positive metal is a dull grey alloy extremely crystalline and brittle, and is cast into cylinders abont 20 mm. long by 7 mm. diameter. The composition of both these alloys is kept secret. Alternate pairs are separated by small square plates of mica. The elements can with readiness be combined either for quantity or intensity. Thus the eighty elements may be used together in one series, or in two series of forty elements, or in four series of twenty elements.

The battery under consideration differs somewhat from that described in Poggendorff; it is larger; a sliding double groove keeps the burners in one position, exactly midway between the double rows of elements; and arrangements have been introduced in order to prevent radiation from the sides of the flames to the blackened copper radiators, that is, to the cool end of the elements.

According to the maker, the battery is equal to "8 grosse Daniell'sche Elemente." The electromotive force of one element, according to M. Von Waltenhofen, was found to be equal to 1·24 to 1·36 Jacobi-Siemens's unit, while a Daniell's cell (no dimensions given) is equal to twelve of these units. One Noë's elements is said to be equal to 11 of the ordinary bismuth-antimony elements.

On testing the battery of eighty elements, we found it to be somewhat weaker than we expected. It is, however, very difficult to know to what extent the elements may be safely heated. No definite directions are given on the subject by the maker, and as the composition of the alloys is kept secret, one is unable to ascertain their fusing point without sacrificing a pair of elements.

With large iron electrodes placed in a solution of very dilute potash, water was decomposed by the battery at the rate of 22 cub. centimetres per minute. With small platinum electrodes exposing less than one square centimetre of surface in water rendered acid by dilute sulphuric acid, 10 cc. of the mixed gases were evolved per minute. One of Gaiffe's induction coils, capable of giving a spark 15 mm. long, was connected with the battery. A copious stream of sparks 11 mm. long was produced. With a small 6-inch electro-magnet, surrounded by only two coils of wire, the battery produced a portative force of more than 20 lbs., when the gas was turned down so as to be nearly level with the orifice of the burners, and the flame was distant some 9 mm. from the surface of the elements. It is very possible that the battery might be heated to a higher temperature than that employed for decomposing water without detriment. In no case did the upper cylinders glow with even a faint red heat.

Here then we have an instrument which at a moment's notice can be set in action, which consumes a small amount of gas, is tolerably portable, and which is sufficient for all ordinary electro-magnetic experiments, for lecture demonstration of the decomposition of water, ammonia, &c., and for many purposes for which a voltaic battery has now to be used. Four or six of these batteries would be sufficient for all purposes save the electric light; they might be made more compact, and could with ease be placed beneath and at one end of the lecture table. The lighting of a row of gas jets would thus furnish us at any moment with an abundant current of electricity. The battery is, indeed, less strong than one could wish, but the production of it is a step in the right direction; and we look forward to the time when powerful and compact thermo-electric batteries will be found in every lecture-room, and when the lighting of a row of gas jets will, through the medium of such batteries, furnish us at any moment with a powerful electric light.

We are at the outset of invention in this direction; several improvements in Noë's battery seem to us to be both advisable and practicable. Let the elements be enlarged, the brittle cylinders of alloy protected, the radiation of heat from the sides of the row of gas jets to the cool ends of the elements entirely prevented, which is by no means the case now; and, if possible, let a current of cold water flow through pipes interspersed among the cooling plates. Again, let the pressure and amount of gas be indicated, and let the stop-cock admitting the gas be furnished with a projecting pin, moving on a graduated dial, so that any desired amount of gas (pre-determined) can at any time be caused to issue from the burners, and thus any desired strength of current (pre-determined in reference to the heating effect by ordinary electrometrical means) be obtained.

G. F. RODWELL

ON THE MEASUREMENT OF MUSICAL INTERVALS *

IN a series of communications to the *Académie des Sciences* (February 8 and 22, 1869, July 17, 1871, and January 29, 1872), M. Cornu and I have shown that musical impressions are based upon several systems of musical intervals. We were also able to announce, as a preliminary result of experiments not yet completed, the following propositions, which, while they show clearly the origin of discussions that have gone on for more than two thousand years, appear to be capable of putting an end to these discussions, by reconciling the two contrary opinions which have always been entertained upon this subject.

1. The musical intervals formed by the successive sounds of a melody without modulation, belong to the Pythagorean scale, the degrees of which are represented by the following ratios, containing only the factors 2 and 3†: —

do	re	mi	fa	sol	la	si	do
1	$\frac{3^2}{2^3}$	$\frac{3^4}{2^6}$	$\frac{2^2}{3}$	$\frac{3}{2}$	$\frac{3^3}{2^4}$	$\frac{3^5}{2^7}$	2.

2. The intervals formed by the simultaneous sounds of the concords, which are the basis of harmony, belong to very different systems, depending upon the complexity of the cords. Those which form part of the simpler concords of two or three sounds, thirds, sixths, perfect concords, &c., may be included in the scale given in all treatises on physics, the degrees of which are represented by the following ratios formed by the factors 2, 3, and 5 :

do	re	mi	fa	sol	la	si	do
1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2.

To demonstrate these propositions several conditions require to be fulfilled.

In the first place, in the two scales above given, the three different intervals, viz., the major third *do—mi*, the sixth *do—la*, and the seventh *do—si*, differ from one another by the interval called a "comma," the value of which is $\frac{81}{80}$, as will be found on dividing one by the other the fractions which represent these intervals on the two scales. Now this value of the comma is very small, though very perceptible to the ear ; to demonstrate it we must, therefore, seek the assistance of skilled musicians, and employ apparatus of considerable delicacy.

Secondly, to measure the intervals formed by successive sounds it is best to study these intervals not separately, but as they occur in the actual course of a melody. Consequently, if we employ as our means of measurement the process which consists in causing the sounding body to trace out its own vibrations (and in the present state

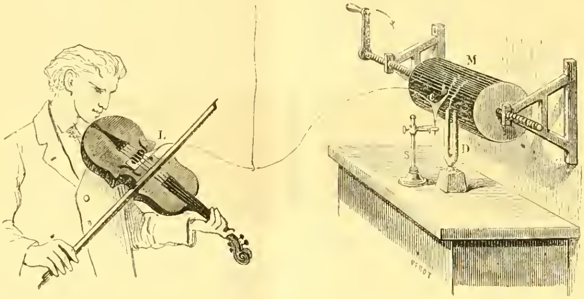

FIG. 1

of science no better method can be adopted), we must have the means of inscribing continuously the sounds which constitute fragments of melodies as they are executed upon an instrument.

Lastly, it is clearly necessary that the registration of the vibrations shall be automatic, and independent of the volition of the observers. The player must have nothing to do with it ; he must not even see it going on, so that his attention may be entirely devoted to the music which he is playing.

After many trials we have succeeded in fulfilling these conditions. The apparatus which we use is very simple, the elements of it being found in every physical cabinet. It will, therefore, be useful to describe it.

Experiment shows that a metallic wire of steel, copper, brass, &c., without tension, and merely supported in such a manner that its vibrations may be executed freely, transmits to one of its extremities, by transverse vibrations, the sounds emitted by a sonorous body fixed to the other extremity. To show this it is sufficient to take two tuning-forks having mirrors attached to them, and tuned exactly in unison. Fix the end of a wire to one of them, and attach to the other end a feather carrying a shining point placed in front of the mirror of the second tuning-fork. On setting one of the forks in vibration, and properly adjusting the feather, the shining point is seen to describe an ellipse characteristic of the unison, and varying in form when a weight however small (a little piece of wax for example) is attached to the tuning-fork fixed to the wire.

A wire five, six, eight, ten, &c., metres long, suspended by narrow strips of caoutchouc, is soldered at one end to a small plate of brass, L, placed between the sounding-board of a stringed instrument and the foot of the bridge, the other end being slightly clasped to a heavy stand S. Near the fixed point a small piece of tinsel (*c*) is soldered on, and to this is attached a feather (*b*), by means of a little soft wax (by this arrangement a greater amplitude of vibration is attained than if the feather were directly attached to the wire). The musician stands in such a position that the wire may not impede the movements of his bow, and plays fragments of simple melodies in slow time (each note lasting at least a second). The vibrations of the strings are transmitted to the bridge, the metal plate, the wire, and, lastly, to the feather, which vibrates synchronously. It only remains to trace these vibrations.

The registering instrument is composed of a metal cylinder, M, the axis of which is furnished with a screw moving a double nut, firmly fixed to a table or to the wall. This cylinder is covered with a sheet of paper, which is blackened by making it revolve over the smoky flame of an oil-lamp. A tuning-fork, D, making from 300 to 500

* Translated from the *Journal de Physique*.

† See the same volume, p. 109, Sur l'Histoire de l'Acoustique Musicale.

double vibrations per second, and carrying a strip of tinsel to serve as an index, is firmly fixed in a vice or in the wall, and arranged so that its index may vibrate in the direction of the generating lines of the cylinder. These vibrations serve to mark the time, and the tuning-fork serves as a chronograph, obviating the necessity of giving to the cylinder a regular and uniform motion. Further, the feather is moved forward, so that its point may just touch the blackened paper, and that it may vibrate quite close to the index, and, like the latter, in the direction of the generating lines of the cylinder.

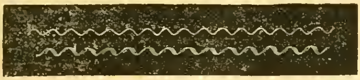

FIG. 2

These arrangements being made, the tuning-fork is set in vibration, either with a bow or by striking it with a stick covered with leather, and the musician plays, while the cylinder is turned at a suitable rate either by the hand or by any convenient motive power.

In this manner a tracing is obtained like that of which a fragment is shown in Fig. 2, each note of the melody being represented by a form of vibration peculiar to itself. The number of vibrations for each note, corresponding to 100 vibrations, for example, of the tuning-forks, is counted, and the ratio of the numbers thus obtained gives the values of the intervals. The vibrations are sometimes complicated with harmonics (Fig. 3), but they are almost always octaves, rarely fifths, very rarely thirds; moreover, it is not possible to make a mistake on this point.

To preserve the tracing after it is detached from the cylinder, it is split longitudinally, dipped for an instant into a 4 per cent. solution of shellac in alcohol, whereby it becomes covered with a very thin layer of unalterable varnish.

If, instead of measuring intervals of melody, we wish to measure the harmonic intervals of two sounds, two strings of the instrument are tuned simultaneously (in the ordinary way), to the third, fifth, sixth, &c., till beats are no longer perceptible, and the ear is perfectly satisfied; the sounds of the two strings thus tuned are then separately traced.

We have made numerous experiments with several persons, in particular melody experiments with M. Léonard, the Belgian violinist, and M. Séligmann, the violoncellist. The mean values of the results obtained with the assistance of these eminent artists are given in the following table; other experiments gave octaves equal to 2.

	Do.	Re.	Mi.	Fa.	Sol.	La.	Si.	Do.
Mean of the results.	1·000	1·128	1·265	1·330	1·500	1·686	1·917	...
Pythagorean Scale.	1·000	1·125	1·266	1·333	1·500	1·687	1·898	2·000
Ordinary Scale.	1·000	1·125	1·250	1·333	1·500	1·666	1·875	2·000
Values of the Comma *	0·013	0·014	0·016	0·017	0·019	0·021	0·024	0·025

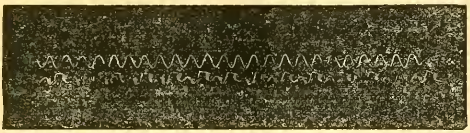

FIG. 3

It is necessary to add that the mean deviations of the experiments rarely exceed the third of a comma. As to the differences between the mean values of the results and the values of the intervals of the Pythagorean Scale, it is a mere fraction of the comma, insensible to the ear. For the seventh alone the difference amounts to five-sixths of the comma; but this result is remarkable, inasmuch as it exhibits a fact well known to musicians, namely, that in the case where the sensitive note Si is resolved upon the tonic Do (which is precisely what occurs in the four cases in which we obtained sevenths), it is perceptibly higher than in the inverse movement.

E. MERCADIER

DISCOVERY OF A LARGE BONE CAVE IN BAVARIA

DURING the cutting of the railway from Nuremberg to Regensburg by the Bavarian Eastern Railway Co., it was necessary to cut directly through a piece of mountain chain in Schelmengraben near Regensburg. It was owing to this that this bone cave was discovered, and its miscellaneous contents were able to be examined and arranged. Since the railway cut right across the middle of the cave, it allowed it to be very thoroughly examined, and under the most favourable circumstances and in daylight, as has been the case in very few other instances. The railway company have given every facility in their power that the cave should be thoroughly examined, and under the direction of Profs. Fraas and Zittel, a gang of men were actively employed for many days, and the objects so obtained were carefully preserved. From the local German papers the following particulars have been obtained, which, allowing for a little local colouring and exaggeration, show the find to have been a most important one, and one that may well come under the notice of the International Congress of Archæology and Anthropology at their meeting this year, where the whole question of bone caves and their contents is to form a prominent subject for discussion.

The cave in question was originally, when first discovered about two years ago, 28 metres (about 91 ft.) long, and was simply a fissure in the Jura limestone which had been enlarged by running water. Its opening was visible half way up the mountain side, partly hidden in dense woods. It stretched from North to South, with a slight turn towards the West of about 15°. The new line of railway cut deeply into the hill side, and during the course of this year has already cut away one half of the cave, but unfortunately the contents were employed on the line. On this account, only the part not touched was able to be excavated and examined, and this was 11 metres (36 ft.) long, 2 metres (6½ ft.) wide, and in the middle 3 metres (9½ ft.) deep. Wood ashes and pieces of coal, together with pieces of pottery, had accumulated to about the height

* These numbers are the *differences* between the numerical value of each interval I, and the mean of this same interval raised by a comma, that is to say,

$$\left(\frac{81}{80} - 1\right) \times I = I \times 0{\cdot}015$$

of three feet, in the midst of which were sharp splinters of flint, and a thick mass of broken and split bones, and the shattered skulls and jaw bones of a heterogeneous mass of animals of all kinds. In the lowest layer no trace of men, either by their remains or by their handiwork, could be found, all the remains consisted of bones of animals, chiefly the cave bear, hyæna, and lion. These cave-dwelling animals appear to have been the first and earliest possessors of the cave. But soon after this men must have discovered the cave and inhabited it, for from this layer up to the newest layer of all the presence of man is clearly shown, and the remains of their feasts and of their daily life are mingled with those of the previously-named animals. The most numerous remains consist of flints of which many thousand were found, but these do not appear to have been used as implements, but come rather under the category of flint-flakes, the chippings from knives, saws, lances, &c. The most perfect one found is three inches long, and half-an-inch wide, and is toothed like a saw, and was probably used as such to saw off the ends of the deer's horns, of which quantities were found.

In order to judge the age in which men began to inhabit this cave, we must examine the remains of the bones and skeletons of the animals which they hunted, and whose flesh was eaten in the cave. The most conspicuous amongst these is the cave bear, and although it might at first sight appear very difficult to recognise in the broken and burnt bits of bone that they really do belong to the cave bear, nevertheless, careful comparison with specimens in museums has proved that this is the case. Every care seems to have been made to utilise to the utmost all parts of this animal, which was apparently the most important game in the surrounding forests, and which no doubt required much labour and time to capture. At the same time, together with the bones of the cave bear are found bones of the elephant and of the rhinoceros, but not many in comparison. These remains, however, show conclusively, by the way in which they have been split up and broken, that man hunted these animals at the time he first appears on the scene. Remains of horses, oxen, cats, and wolves were also met with, and in proof that the early inhabitants were not unmindful of fish, there are the bones and scales of large pike and carp. The smaller bones of mice and frogs do not appear to owe their origin so much to man as to the owls which seem to have held possession of the cave as well.

Great interest attaches to the fragments of pottery which were found in the cave, and which rival the flint flakes in quantity. It appears to have been all hand made, but although rough, shows considerable beauty of shape and form. It is possible to put together from the fragments one or two more or less complete vessels, which, however, show great diversity as to size, &c., some being between 10 and 20 centimetres in diameter. The material of which they are made appears to be clay mixed with sand, but few, if any, seem to have been regularly burnt. Much of the pottery is ornamented with lines or rows of dots, which run in zigzag lines over the wider parts. The internal smoothness would appear to be due to the river mussel, Unio, obtained from the River Naab which flows close by, and of which many well rubbed and polished specimens were found in the cave. A block of granite with one side rubbed smooth, and by long usage appearing quite polished, can hardly be anything else than a well-worn millstone, and this is rendered more probable by two holes having been bored into the upper side as if for the purpose of affixing a handle. The presence of this millstone would indicate the cultivation of land in the immediate neighbourhood, which is confirmed by the finding of several spindles made of clay.

The different objects found in this cave are of great interest, as they apparently run counter to the somewhat hard and fast lines which have been drawn as to different well marked periods in the early history of man.

THE PARIS SIEGE BALLOONS

THE lessons learnt at Paris in regard to balloon navigation will be of great value in any future employment of aërial machines, and the statistics which have now been collected and published are well worthy of a brief notice. As many as sixty-four balloons, it appears, actually started from Paris in good order, with a *personnel* of 161, and with something like three million letters. The first ascent was made on the 23rd of September, 1870, by M. Duruof with safety, and the fifth balloon carried in it Gambetta, who arrived without accident at Amiens after a voyage of four hours. M. Janssen, whom, it will be remembered, was desirous of watching the approaching eclipse in the south of Europe, left Paris with all his instruments complete in the balloon Volta, on the 2nd of December, landing at Savenay (Loire Inférieure) after a journey of five hours and a half. One of the later voyages was made with two cases of dynamite, to be dropped and exploded at a seasonable moment; but fortunately for the enemy no such opportunity presented itself. The last balloon left Paris on the 28th of January, 1871.

Of these sixty-four balloons only seven were unsuccessful in fulfilling their purpose, two of the machines being utterly lost at sea; while five were captured by the enemy. As many as sixteen actually fell within the hostile lines; but the aëronauts were in most cases too quick for their pursuers, and managed to escape. Indeed, of the five actually taken only three were really captured by the enemy's forces, the other two falling in fact upon German soil, namely, in Prussia and Bavaria. The most interesting voyage was certainly that of M. Rollier, who travelled safely from Paris to Christiania in fourteen hours, after a journey across the North Sea of nearly twelve hours. Of the two lost at sea, one was observed to go down by some sailors at Rochelle; while of the other nothing certain is known.

The regularity with which the balloon service was conducted during the winter of 1870 under grave disadvantages will be remembered by all who studied the daily newspapers at that period, the news from the French Capital never being interrupted for more than three or four days together. Most of the aërial machines contained 2,000 cubic metres of gas, and one of them consisted of twin spheres tethered together; they were usually started from the Orleans or North railway stations at nightfall, so that they might escape the vigilance of the German troops posted round the city. Besides a freight of letters the majority carried baskets of pigeons, and in five cases dogs, destined to return with news to the beleagured city; how well the pigeon-post itself was organised may be gathered from the fact that fifty thousand messages were sent into Paris by its means alone.

Some attempts were made by MM. Tissandier Frères to return to Paris by means of aërial machines impelled by favourable winds; but two successive essays made from Rouen on the 8th and 9th of November were quite fruitless. M. Jules Godard, the aëronaut, and M. Nadar were the principal agents in organising the balloon service.

NOTES

AT the Anniversary Meeting of the Royal Geographical Society, held on Monday last, the Royal medals for the encouragement of geographical science and discovery were presented. The Founder's Medal was given to Sir W. Baker for Colonel Henry Yule, C.B., in recognition of the eminent services he has ren-

dered to geography in the publication of his three great works—"A Mission to the Court of Ava," "Cathay, and the Way Thither," and "Marco Polo." The Patron's or Victoria Medal was personally presented to Mr. Robert Berkeley Shaw, for his journeys in Eastern Turkestan, and for his extensive series of astronomical and hypsometrical observations, which have enabled us to fix the longitude of Yarkand, and have given us, for the first time, the basis of a new delineation of the countries between Leh and Kashgar. A gold watch was also awarded to Lieut. G. C. Musters, R.N. (now travelling in America, and represented at the meeting by his brother), for his adventurous journey in Patagonia, through 960 miles of latitude, of which 780 were previously unknown to Europeans; and the sum of 25*l.* to Karl Mauch, in acknowledgment of the zeal and ability with which he has devoted himself for a series of years to the exploration of South-Eastern Africa. Mr. Shaw, who was addressed by the gallant president as "the hero of the hour," was loudly cheered by the meeting when he briefly acknowledged the honour paid to him. The annual geographical medals offered by the Society to the chief public schools were presented to the following successful competitors:—Physical Geography: Gold medal, S. E. Spring-Rice, Eton College; bronze medal, A. S. Butler, Liverpool College. Political Geography: Gold Medal, W. G. Collingwood, Liverpool College; bronze medal, W. C. Graham, Eton College. The president, Sir Henry Rawlinson, K.C.B., then delivered his anniversary address, which was chiefly occupied by tributes to distinguished members who have died during the year, and to a statement of the most recent information respecting the Livingstone Search Expedition.

THE President of the Society of Telegraph Engineers has issued invitations for a *conversazione*, to be held in Lord Lindsay's Laboratory on June 6, at 9 P.M.

AT the meeting of the French Academy of Sciences on May 20, M. Tresca was elected a member of the section of Mechanics in the room of M. Combes, deceased.

THE Dutch Society of Sciences in Haarlem has awarded the great gold Boerhaave Medal to Mr. H. C. Sorby, F.R.S., and elected him a foreign member. This medal, of the gold value of 500 gulden (about forty guineas), has been established three years, and is to be given away every two years to those who during the last twenty years have made themselves particularly meritorious in different departments of Science, according to a fixed rotation, and this year was given for the branch of mineralogy and geology.

AT the last meeting of the Royal Society of Edinburgh, Prof. Turner was presented with the Neill prize and gold medal for the triennial period ending 1871, for his papers on the "Great Finner Whale," and on the "Gravid Uterus and the Arrangement of the Fœtal Membrane in the Cetacea." The Keith prize, for the biennial period ending May 1871, was awarded to Prof. Jas. Clerk Maxwell, F.R.S., for his paper "On Figures, Frames, and Diagrams of Forces."

THE *Medical Times and Gazette* states that M. Jules Simon, the Minister of Public Instruction in France, has accepted in principle the creation of a Faculty of Medicine at Bordeaux to replace that of Strasburg, and that a commission has been appointed to report upon the project in question. It is also in contemplation to establish a School of Medicine and a School of Pharmacy at Lyons.

THE *Revue Scientifique* of May 18th gives an account of the inauguration of the German University of Strasburg, with an interesting sketch of the history of the university under its original German rule, and subsequently to its incorporation into the French Empire by Napoleon I.

MR. FLOWER, the Professor of Anatomy at the Royal College of Surgeons, London, is anxious to collect and exhibit in the Museum of the College a complete set of skulls of all the varieties of the dog. The collection will be of great value as bearing on the question of the variability of the skeleton in domesticated varieties of the same species.

THE following excursions have been arranged by the Geologists' Association to take place in June:—Excursion to Guildford, Saturday, June 1, Directors, Prof. T. Rupert Jones, and Mr. C. J. A. Meyer. Upon arrival at Guildford the members will proceed to inspect the very instructive exposure of the Chalk and Lower Greensand in the neighbourhood of Guildford. The physiography of the district is also extremely interesting, and is well seen from several elevations which will be visited. Excursion to Bromley and Chiselhurst, Saturday, June 15, Director, Mr. J. W. Ilott. Leave Charing Cross for Shortlands Station. Visit the waterworks at Shortlands, and inspect section of well. Walk along railway to Bromley, and examine five sections of the Woolwich and Reading Series in the Palace Park and at the Brick Works. Walk through Sundridge Park, and inspect Sections of Shell Beds. Subsequently visit the Chalk Caves of Camden Park, and return from Chislehurst Station. Excursion to Hendon and Finchley, Saturday, June 22, Director, Dr. Henry Hicks. On arrival at Hendon Station proceed, under the guidance of Dr. Hicks, to inspect the Sections of the Glacial Drift in the neighbourhood of Hendon and Finchley. Return from Finchley Station. The long excursion of the session will be to Ludlow and the Longmynds in July.

DR. STIMPSON, the eminent director of the Chicago Academy of Sciences, has been engaged during the past winter in prosecuting deep-sea explorations in Florida. He first accompanied the United States Coast Survey steamer *Bibb*, when making soundings between Cuba and Yucatan for a submarine cable, but found the sea bottom very poor in animal life. We have previously mentioned that the bottom temperature in the deepest water was about 39·5° F., which may possibly account for the scanty fauna. The bottom consisted of sand and Globigerinæ mixed, in which scarcely anything occurred but shells, mostly dead. Some of the species were identical with those obtained by Mr. Gwyn Jeffreys at a similar depth off the European coast. On their way back from the cable work, the expedition made one haul of the dredge off the Cuban coast, near Havana, in 250 fathoms water, and obtained a superb specimen of the very rare *Pentacrinus Caput Medusæ*, the first ever obtained so near the American coast, and perhaps hardly represented as yet in any of the museums. After returning to Key West the doctor took charge of the dredging on board the Coast Survey steamer *Bache*, but ill-health prevented his prosecuting this to any extent.

Harper's Weekly states that Prof. J. D. Whitney, the accomplished State Geologist of California, has undertaken to collect the facts in regard to the late earthquake, and has proceeded, with this object to Inyo County, the centre of its most active manifestation. As. Prof. Whitney has made a specialty of the study of earthquakes and the accompanying and resultant phenomena, we have no doubt that much light will be thrown upon this interesting topic.

WITH reference to the connection between electricity and earthquakes, the *Pall Mall Gazette* quotes from a Californian paper, the *Inyo Independent*, the following curious statements respecting the prevalence of electrical phenomena at the time of the recent earthquake in that State:—"A few days after the big shock, so called, at Cerro Gardo, very loud thunder was heard during a violent snowstorm. With the exception of the snow, the same thing occurred here, and perhaps at other places in the valley. This is remarkable, because almost unprecedented. Immediately following the great shock, men whose judgment and

veracity are beyond question, while sitting on the ground near the Eclipse Mines, saw sheets of flame on the rocky sides of the Inyo Mountains, but half a mile distant. These flames, observed in several places, waved to and fro, apparently clear of the ground, like vast torches. They continued for only a few minutes. In this office, one day last week, while one of the proprietors was running a large number of sheets of flat-cap paper through a job press, these sheets, after leaving the press, were affected by the movements of the operator's hand, as a strong magnet would affect iron filings. When his hand was near them, the whole pile, or at least a hundred of them from the top, seemed to float in the air, like tissue paper in a slight breeze The top sheet would rise at each end up to the hand when held four inches above it, and thus by attraction be moved entirely away from the others. At times during the night sparks of fire were repeatedly emitted from a woollen shawl on being touched by the hand. At the Kearsarge Mill, located at an altitude of nearly 80,000 feet above the sea, the following occurrence was noted by Harry Clawson and P. J. Joslyn :—The former, while sitting with his knees within three inches of a cast-iron stove, felt a peculiar numbing sensation, and, supposing his limbs were 'asleep,' essayed to rub them with his hand. As soon as his hand touched his knee he felt a shock, and immediately after, and for a couple of seconds, a stream of fire ran between both knees and the stove. We will here state, on the authority of a man who had an opportunity of knowing, that the item going the rounds to the effect that no movement of the earth was observable 300 feet underground in the mines is not correct. At Cerro Gardo, and also at the Eclipse Mine, the rocking motion was distinctly observed, especially in the timbering. Small particles of rock were detached, and in both places the miners went to the surface in alarm ; but at Cerro Gardo they soon resumed work as before."

TELEGRAMS just received from New York speak of a terrible disaster to the seal fishing fleet on the coasts of Labrador and Newfoundland. Four steamers and nearly forty sailing vessels are reported to have been wrecked among icebergs and the ice fields by a hurricane. The whole of the crews, which averaged ninety men, perished. Later accounts, however, state that the reports of the disaster to the fishing fleet were exaggerated. Only twelve vessels were lost.

A TERRIFIC hurricane visited Madras on May 2. It is described as being the most violent that has occurred there for many years, the devastation occasioned among the shipping being of a terrible character. Nine English vessels are spoken of as having become total wrecks, and the destruction of life is said to have been very great.

NATAL papers describe the great brilliance of the Aurora Australis witnessed both in that colony and in Cape Colony and the Free States on Feb. 4. The *Natal Colonist* of March 5 speaks of the southern aurora being not unfrequently visible there in broad daylight.

A REMARKABLE story from Newfoundland is detailed in a letter to the *New York Times* of April 15, to the effect that a Danish brig just arrived, which had left Disco on March 1, brought information that the *Polaris*, under Captain Hall, had been there for two days undergoing repairs and procuring a fresh supply of provisions. The account goes on to say that on the evening of February 8 the *Polaris* encountered extremely heavy weather, and while lying to, owing to the shallowness of the water, ran among ice snags, which caused a leak in the vessel, and made it necessary to proceed to Disco for repairs. Mysterious intimations were given of wonderful discoveries which had already been made by the *Polaris*, indicating the existence of a genial atmosphere and open seas in the extreme north. Plants indigenous to southern climes were detected in the ice, while a floating stick of wood proved to be northern birch. Throughout the whole of the month of February very little ice was seen, and the skies were literally alive with meteors of the most gorgeous description. On Christmas-day the ship was hemmed in by a heavy field of ice, but the weather was as pleasant as an Italian spring day. Such was the reluctance of Captain Hall to have the further discoveries which he is expecting to make shared by rival expeditions, that, according to the writer, he did not send word of his return to the Secretary of the Navy. The entire story bears little evidence of credibility, and will at least require further confirmation before it can be accepted.

CAPTAIN THOMAS LONG, so well known as the discoverer, in 1867, of Wrangell's Land, situated about seventy to one hundred miles north of Cape Yakan, in Siberia, has written a letter in reference to the plan of exploration by Mr. Octave Pavy, to which we have already referred. While indorsing the idea presented by Mr. Pavy, he takes occasion to claim it as his own, having, as he states, urged this route as long ago as 1867, the time of his first discovery. He does not think that Mr. Pavy will be able to pass through the channels between Spitzbergen and Greenland, or between Nova Zembla and Spitzbergen, as those passages have always been found blocked with ice, and it would be impossible to winter in the ice in such a raft as he has constructed. He thinks it possible that the North Pole may be reached from Wrangell's Land, but that it would be necessary for him to return for winter quarters ; but to endeavour to return into the Atlantic with such a craft would be the height of folly. He believes that a vessel, properly fitted for the purpose, could make the passage from Behring Strait to the Atlantic in one year from the time of passing Behring Strait.

PROF. O. C. MARSH describes in the *American Journal of Science* for May four new species of fossil birds, three of them belonging to the genus *Graculavus*, probably closely allied to the cormorants of the present day, and occurring in the cretaceous deposits of New Jersey and of Kansas. The fourth is a species of *Palæotringa*, from the cretaceous greensands of New Jersey. The same paper contains a more elaborate description of the very remarkable new fossil bird named by him in January last *Hesperornis regalis*. This has numerous peculiarities, although it seems to resemble most closely the common loon of the United States. It was, however, much larger, as its complete skeleton would measure nearly six feet from the tip of the bill to the end of the toes. It occurs as a fossil in the gray shale of the upper cretaceous formations near Smoky Hill Fork, in Western Kansas.

WE learn from Rockhampton, Queensland, that on January 31 a fisherman named W. C. Easton discovered an alligator's nest on Eighteen-mile Island, eighteen miles above Rockhampton in the Fitzroy River. The mother was in the nest when Easton made the discovery, but she ran off, "bellowing like a cow after her calf," as Easton fired a shot from his double-barrelled gun into the river. She was about nine feet long. As Easton went up to the nest, a large carpet snake was about to enter it, but the snake, too, fled before his approach. On examining the nest, Easton discovered sixty-seven eggs, which he took away. The eggs were rather larger than a goose's egg, measuring $6\frac{1}{2}$ inches in circumference one way, by $8\frac{1}{2}$ inches the other ; $3\frac{1}{4}$ inches in length, and nearly white, and in shape almost a true ellipse, but rather too long for their breadth. Mr. Easton placed four of the eggs under a hen, and twelve in straw, in the hope of rearing and domesticating some young alligators. The Fitzroy is the most southern river in which the alligator is found on the East Coast of Australia, and is just within the tropics.

ON OPTICAL PHENOMENA PRODUCED BY CRYSTALS SUBMITTED TO CIRCULARLY POLARISED LIGHT*

ON a former occasion I exhibited some phenomena depending upon circular, or, as it was then also called, successive polarisation, and in particular I adopted and explained a method for producing circularly polarised light devised by Sir Charles Wheatstone. I propose on the present occasion to pursue the subject into some of its ulterior consequences. In terms of the wave theory, light is said to be circularly polarised when the vibrations are circular, as distinguished from plane polarisation, when they are rectilinear. And further, it is known from mechanical principles that a circular vibration may always be produced by the combination of two rectilinear vibrations, the amplitudes or extents of which are equal, and whereof one is in advance or in rear of the other by one or by any odd number of quarter-wave lengths. In the former of these cases the circular motion will take place in one direction, say right-handed, in the latter in the opposite, say left-handed. The contrivance used for producing circular polarisation this evening is known by the name of a "quarter undulation plate," and consists of a plate of mica split to such a thickness that one of the two rays into which plane polarised light is divided on entering it is retarded by an odd number of quarter-wave lengths behind the other.

The optical phenomena produced by crystals when submitted to polarised light are usually divided into two classes, viz. (1) those arising from the use of parallel light, and consisting of broad sheets of colour; and (2) those due to convergent light, and consisting of the rings and brushes, the general character of which is well known. I propose to take a few specimens from each class, and to examine the modifications which the known phenomena undergo when the light is both polarised and analysed circularly, *i.e.*, when one quarter-undulation plate is interposed between the polariser (Nicol's prism) and the crystal to be examined, and the second between the crystal and the analyser (Nicol's prism).

In the first place, it is known that if a plate of selenite be placed in an ordinary apparatus when the polariser and analyser are either parallel or crossed, there are four positions at 90° apart in which the plate will produce colour; and further, that if the analyser be turned through 90° the same result will be obtained, except that the colour will be complementary to that first seen. The intensity of the light at any given point is then given by the formula:

$$\cos.^2 s - \sin.\ 2\,i \sin.\ 2\,(i - s) \sin.^2 \frac{\theta}{2}$$

where i and s are the angles made with the original plane of polarisation by the principal sections of the crystal and of the analyser respectively, and θ is the retardation.

If, however, the two quarter-undulation plates (say the plates A and B) be introduced, the light undergoes the following processes:—First, it is plane polarised by the polariser; secondly, the plate A being placed so that its axis is inclined at $\pm$ 45° to the original plane of polarisation, the light undergoes right or left-handed circular polarisation, and in that condition falls upon the crystal; thirdly, in their passage through the crystal C the rays are each divided into two, whose vibrations are at right angles to one another, and whereof one is retarded in proportion to the thickness of C; fourthly, the plate B being placed so that its axis is parallel or perpendicular to that of A, each of these sets of rays is circularly polarised, one set right-handed, and the other set left-handed; fifthly, these two oppositely circularly polarised sets of rays combine, according to known mechanical laws, on emerging from B into plane rays, in which the planes of polarisation of the different colours of the spectrum are turned through different angles. Hence finally by turning the analyser round we shall cross these various planes in turn and successively extinguish the different colours, leaving the complementary colours visible. The system of plates A C B consequently acts in this respect like quartz. It is, however, to be observed that if the plate B be turned from one of the two proposed positions to the other, the directions of motion in the two emergent circularly polarised rays, and consequently the planes of polarisation of the different colours, will be reversed; in other words, with the plate B in one position we shall imitate a right-handed, with the plate B in the other a left-handed, quartz. The intensity of the light at any point is then given by the formula:—

$$\sin.^2 \frac{\theta}{2} \text{ for one position,}$$

$$\cos.^2 \frac{\theta}{2} \text{ for the other.}$$

Again, if the plates A B retaining either of the positions before indicated, the crystal C be turned round in its own plane; then, since the light emerging from A and B is circularly polarised, it has lost all trace of direction with reference to the positions of the polariser and analyser, and consequently no change of tint will be observed. The same is abundantly clear from the formula written above, because the only term it contains depends upon the retardation within the crystal C. This experiment was made by Airy.

If the plates A and B have their axes directed 45° on either side of the axis of C, and the three plates be turned round as one piece, the colour will remain unchanged; while, if the analyser be turned, we have the colours shown in the regular order. If the plates A and B have their axes directed at 45° on the same side of the axis of C, and the pieces be turned round bodily as before, the colours change in the same order as above, and go through their cycle once in every 90° of rotation; and if the analyser be turned in the same direction the colours change, but in the reverse order. The explanation of this is to be found in the fact that when the plates A and B are crossed, the retardation due by A is compensated by that due to B; so that the only effective retardation is that due to the crystal C. But upon this depends the rotation of the plane of polarisation; if, therefore, the polariser and analyser remain fixed, the colour will remain unaltered. When the plates A and B have their axes parallel, there is no compensation, and the colour will consequently change. This experiment was made by Fresnel. The mathematical expressions for the intensity of the light in the two cases respectively are:—

$$\cos.^2\left(j + i + \frac{\theta}{2}\right), \text{ and } \cos.^2\left(j - i - \frac{\theta}{2}\right),$$

where i is the angle made by the principal sections of A with that of the polariser, and j that of the principal section of B with that of the analyser. The first expression is obviously unchanged when the angle between the polariser and analyser, viz. $\frac{\pi}{2} + i + j$, is unchanged.

It should be added that the rotation of the plane of polarisation, and consequently also the sequence of tints, does not follow exactly the same law in the above cases as in quartz.

We now come to the case of convergent light, that is, to the phenomena of crystal rings. And let us examine the effects produced by the same arrangement as before, viz., two quarter-undulation plates, A, B, one in front and one behind the crystal C. To quote from Mr. Airy:—"The first thing that strikes us in this combination is that there is nothing, except in the crystal, that has any respect to sides. For the only incident light is circularly polarised; the only light allowed to emerge is circularly polarised. The appearance, therefore, of the coloured rings, &c., must be such as conveys no trace of any plane of polarisation, and must not vary as the crystal is turned round. In the common exhibition of the coloured rings the principal trace of the planes of polarisation is in the uncoloured brushes. In uniaxal crystals they form an eight-rayed star, composed of two square crosses, inclined at an angle equal to that between the planes of polarisation, every ray of which separates complementary rings. In biaxal crystals they compose two pairs of rectangular hyperbolas, the angle between whose asymptotes is the same as that between the planes of polarisation, and whose branches divide complementary rings. The two crosses or two sets of hyperbolas unite when the planes of polarisation are parallel or perpendicular. But in the case under consideration the rings exhibited by crystals will not be traversed by any brushes. Uniaxal crystals will exhibit circular rings without a cross; and biaxal crystals will exhibit complete lemniscates, without any interruption from curved brushes." And it is further to be noticed, as the formula given above indicates, that the centres of the rings will be bright or dark according as the analyser stands at 0° or 90°.

To pursue this matter further. Suppose that, the arrangements remaining otherwise as before, the analyser be turned round; then in any position intermediate to 0° and 90° the rings

* Lecture delivered at the Royal Institution of Great Britain, May 3, 1872, by W. Spottiswoode, Treas. R.S.

will be contracted and extended in opposite quadrants until at 45° they are divided by two diagonals, on each side of which the colours are complementary. Beyond 45° the rings begin to coalesce, until at 90° the four quadrants coincide again. During this movement the centre has changed from bright to dark. If the motion of the analyser be reversed, the quadrants which before contracted now expand, and *vice versâ*. Again, if the crystal (say positive) be replaced by another (say negative), the effect on the quadrants of the rings will be reversed. This method of examination therefore affords a test of the character, positive or negative, of a crystal.

A similar process applies to biaxal crystals; but in this case the diagonals interrupting the rings are replaced by a pair of rectangular hyperbolas, on either side of which the rings expand or contract, and the effect is reversed either by reversing the motion of the analyser, or by replacing a positive by a negative crystal, or *vice versâ*. The experiment may then be made in biaxal crystals, by turning the analyser slightly to the right or to the left, and observing whether the rings advance towards or recede from one another in the centre of the field. In particular, if, polariser and analyser being parallel, the plate A have its axis in a N.E. direction to a person looking through the analyser, the plate B its axis in a N.W. direction, and the crystal be so placed that the line joining the optic axes be N.S., then on turning the analyser to the right the rings will advance to one another if the crystal be negative, and recede if it be positive. The mathematical expression for the intensity of the light at any point P is in this case

$$\tfrac{1}{2}\ (1 + \sin.\ 2\,j \cos.\ \theta + \sin.\ 2\,b \cos.\ 2\,j \sin.\ \theta),$$

where b is the angle between the principal section of C through P and the principal section of B, and j the angle between the principal sections of B and the analyser. This shows that when the polariser and analyser are parallel or crossed at 0° or 90°, and consequently $j = 45°$ or $135°$, the expression is independent of b, *i.e.*, the intensity is the same throughout circles about the centre, but that when the polariser and analyser are crossed we have an expression of the form

$$\tfrac{1}{2}\ (1 \pm \sin.\ 2\,b \sin.\ \theta),$$

the sign of the second term depending upon the direction in which the analyser has been turned, and also upon the sign of θ, that is, upon the character (positive or negative) of the crystal.

The dispersion of the planes of polarisation effected by the passage of plane polarised light through a plate of quartz cut perpendicular to the axis may be rendered visible by interposing such a plate of quartz between the polariser and a uniaxal or biaxal crystal, when the analyser is at 90°, *i.e.*, when dark brushes are formed. In this case the brushes cease to be black, and are tinged throughout with colour. The analyser must, however, be turned back or forward, according as the quartz be right-handed or left-handed, in order that it may cross in succession the planes of polarisation of the different coloured rays, and so produce the most vivid effects. The dispersion of the brushes by a plate of quartz may, however, be studied by employing an additional polariser and quartz plate between the source of light and the whole system previously used. By turning this polariser round we extinguish each ray of the spectrum in turn, and tint the whole field with the complementary colour. The brushes will then appear to revolve about their centre, as the tints vary continuously from one end of the spectrum to the other. If the polariser be turned still farther round, the tints which had changed continuously from red to violet, or *vice versâ*, change suddenly from violet to red, or *vice versâ*, and the brushes jump suddenly back to their original position.

This last optical arrangement may be employed to examine the more important phenomena of the dispersion of the optic axes produced, not by a quartz plate between the usual polariser and crystal, but by certain biaxal crystals themselves.

BOTANY

The Leaves of Drosera

In a recent note to the Paris Academy of Sciences, M. Ziegler writes as follows:—

The hairs on the leaves of Droseras exude at their extremity a small drop of glue, by which insects are caught. Whenever an insect becomes attached, the exterior threads bend over it, covering it like the fingers of a hand, and do not straighten again till some days after, when a fresh drop exudes for a fresh prey.

In studying these remarkable plants, I noticed that all the albuminoid animal substances, if held for a moment between the fingers, acquired the property of making the hairs of the Drosera contract. I also observed that such substances, when they had not been in contact with a living animal, had no visible action on the hairs. This shows that the simple contact of the fingers communicates to inert animal substances a property which they did not possess before.

These same animal substances thus prepared lost this singular property when they were moistened several times with distilled water, and dried each time in a water-bath. This is a convenient mode of preparing the substances for experiment.

The contraction of the hairs is not caused by animal heat, which the fingers may have communicated to the animal substances, for the hairs contracted equally when the substance had been cooled before placing it on the leaf.

The perspiration of the fingers cannot affect the phenomenon, for the property can be communicated to animal substances across fine waxed paper. And the result is not affected if the substances are first covered with a coating of wax, thus preventing any chemical action of soluble matters which the animal substances may contain.

A living animal thus communicating by simple contact new physical properties to an inert body, it was important to know whether, by increasing the amount of transmission, we should observe any change in the vital state of the animal. Some rabbits were enclosed in light wooden cages. These were of such a size that their sides were always in contact with the hairs of the animal at one part or other. To the outside of the cage were attached bags of cloth or paper, containing (for each cage) two kilogrammes of dried serum (albumen from blood). Other rabbits were placed in exactly similar cages, but without the albumen. Their food consisted of 25 grammes of hulled oats every twenty-four hours, with cabbage leaves at discretion.

At the end of some days, the rabbits that had been in contact with the albumen became diabetic in a high degree (though without saccharine matter); the urine was given in normal quantity, but the loss in ammoniaco-magnesian phosphate was very great, and these rabbits deteriorated and lost weight. The other rabbits, which had not been in contact with albumen, remained in their normal state, and even gained weight.

It was interesting to ascertain if the avidity of the Drosera for insects was insatiable, and to find what would be the effect on it of increasing the contact of a living animal. Some dozens were accordingly placed, with a small clod of earth and sufficient water, in light platinum capsules. These capsules were each placed in a sheath containing blood albumen, which had previously been held for half an hour in the hand. At the end of twenty-four hours all these Droseras had become quite insensible to insects and to organic animal bodies modified by living contact. The properties of these plants were reversed, and strange to say, their hairs were found to contract under the influence of organic matters which had previously been in contact with paper packets (of double or triple envelope) containing sulphate of quinine. Organic matters influenced in this purely physical manner by sulphate of quinine have no contractile action on the hairs of the Drosera in their normal state. The plants whose physical properties have been reversed by the influence of albumen in the above way, could be restored to their normal state by placing them for twenty-four hours with the platinum capsule on a packet of sulphate of quinine. This method may be adopted whenever, from any cause, the leaves have become insensible to insects. In every case the contraction of the hairs is always slow; it commences visibly in about a quarter of an hour, and is often not complete till after several hours.

Among vegetable matters seeds only are impressible in the way referred to, and the experiments mentioned (which were made with albuminoid animal substances) may be repeated with these.

Nature of Diatoms

In a recent essay by Prof. Adolf Weiss, of Lemburg ("Zum Baue und der Natur der Diatomaceen"), it appears to be demonstrated that the siliceous investment of these little plants has cellulose for its base. The silex is infiltrated to a variable extent in the different families, and the mode of its deposition can to a certain extent be ascertained by examination with polarised light. In opposition to the opinion hitherto generally admitted, Prof. Weiss shows that the siliceous coal is capable of

polarising light; and he has found also that it contains a certain amount of iron-oxide compounds, which are for the most part in an insoluble condition. He strongly objects to the view that the *Diatomaceæ* are one-celled organisms, but contends that each frustule is composed of numerous very minute but perfectly individualised cells. The different markings on the frustules—areolæ, ribs, crests, &c.—are in no way caused by the contour lines of the several cells of which they are composed. The size of the cells is very variable. In *Triceratium favus* they are as large as 0·008 of a millimetre, whilst in *Hyalosira delicatula* they do not exceed 0·00025 of a millimetre. Each cell is arched, and, as a rule, prolonged into a papilliform process at its centre. The papillæ are the cause of the moniliform or pearl necklace-like markings of diatoms when examined with high powers, and which appear as striæ with low powers. The large cavity between the two frustules is, he thinks, comparable to the embryo-sac of higher plants; and Weiss has succeeded in observing the development of new individuals in it. The product of this new individual indicates the alternation of generations in the *Diatomaceæ*.

SCIENTIFIC SERIALS

THE first number of *Zeitschrift für Ethnologie* for the current year (1872) opens with a paper by A. Bastian on "The Position of the Kaukasus in relation to the history of the migration of nations," in which the author points out the importance of studying the hydrography and orography of a country before we attempt to trace the origin of its inhabitants. Mountains and streams afford more stable evidence in regard to ethnological centres of origin than the ever-fluctuating combinations of language. Thus, for the history of our own Continent we can have no more important standpoint than the Kaukasian range, which forms the boundary line between Europe and Asia, from which rivers open the way into the Caspian and Black Seas. Herr Bastian next traces the various directions taken by successive waves of population after they reached the Steppes between the Don and the Dnieper, which long formed the meeting-place of the Scythio-Sarmatian races, and often witnessed the fierce encounter of rival hordes, whose defeat or success on that great battle-field of nations decided the fate of future races. The relation of the nomadic races of Asia to the Persian Empire is of special interest to us, since the latter by its control over the destinies of the western half of the Asiatic continent has exerted the most important influence on the ethnological history of Europe. In Asia the course of civilisation has followed the line of the Steppes; and the nomadic tribes who possessed horses have spread themselves through every pastoral district, amalgamating at times with the earlier settlers, but more generally organising themselves into hostile bands, whose leaders became the founders of equestrian dynasties, and raised thrones for themselves in Central and Western Asia. The author follows at length the progress of Parthian and Persian conquests and migrations, and, after considering the anatomical features and cranial dimensions and forms of the various races, which have given conquerors to the world, discusses the probable bastard or mixed origin of those inferior subjected races, who from time to time have risen against their masters, and asserted their right to freedom, as in the case of some of the Servian tribes against their Pannonian lords, and various Mestizoes or Creoles in Africa and America.—The remaining papers in this number are below the usual standard of the *Zeitschrift für Ethnologie*. We have a paper by Dr. E. v. Martens "On the Different Uses of the Conchilia," originally read to the Anthropological Society of Berlin, which is little more than a *résumé* of what G. E. Rumph, P. Bonanni, Johnston, and Mr. Woodward have given in their semi-popular works on subjects of conchological interest. Dr. Martens also contributes a translation of a paper on the geography, history, and statistics of the Island of Puerto Rico, by S. Bello, of Espinosa. We learn that while sugar and coffee constitute the riches of the island, all the tropical fruits abound, and the excessive annual rainfall maintains a vigorous and verdant vegetation. The hot moist climate is unhealthy, and dysentery, yellow fever (vomits), and remittent fevers of various kinds prevail. The population has, however, gone on steadily increasing during the last forty years, notwithstanding the diminution in the numbers of the slaves, amongst whom the deaths have of late years exceeded the births in the ratio of from 5 to 10 per cent. In 1839 the population was 319,000, in 1870 it had risen to 646,360; in the latter year the number of the slaves had fallen to 32,000, after being 42,227 in 1866, thus giving a diminution of 25 per cent. in four years.—M. de Quatrefages' history of Prussian aggrandisement, which first appeared in the *Revue des Deux Mondes* (1871), under the title "*La Race Prussienne*," has called forth an impassioned and indignant rejoinder in this number of the *Zeitschrift für Ethnologie*. We should be more disposed to concur in the line of argument adopted by the writer in refutation of M. de Quatrefages' too sweeping assertion that Prussians are Finno-Slaves with only a slight admixture of French and German blood in the higher classes, if he had not allowed personal rancour and national hate to over-weigh every consideration of courtesy, justice, and reason. We think an ethnological journal is not the place for international warfare.

Annalen der Chemie und Pharmacie, viii. Supplementband, 2 Heft.—The first 100 pages of this number are occupied by an important theoretical paper "on a periodical law of the chemical elements," by Dr. Mendelejeff; the author has arranged the elements into eight groups and into twelve series; there seems to be a most curious regular progression, both in the atomic weights, the atomicities, and in the chemical proportion of these groups. To take for example the third series of elements, starting from group 1 to 7, we find the following:—Sodium^{i} 23, Magnesium^{ii} 24, Aluminium^{iii} 27·3, Silicon^{iv} 28, Phosphorus^{v} 31, Sulphur^{vi} 32, Chlorine 35·5, it will be seen that the first named is a very positive element, and that the positive character gradually changes through the groups until in the seventh we have a powerfully negative body; the atomic weights and atomicities of the elements also increase in a regular manner. In the other series the same kind of relation seems to exist; the author has left spaces in his table for elements not yet discovered, but for which he gives hypothetical atomic weights. The next paper is by Gorup Besanez "on the dolomite springs of the Jura," and is followed by another "on a new class of platinum compounds," by Schutzenberger; by the action of carbonic oxide on platinous chloride at high temperatures three distinct compounds have been obtained, the first containing one equivalent of carbonic oxide to one equivalent of platinous chloride, the second two equivalents of carbonic oxide, and the third one and a half equivalents of carbonic oxide to one of platinous chloride. Linnemann and Zotta have found that by heating glycerine with calcic chloride, small quantities of phenol are formed, and at the same time there is produced glyceric ether. Phenol is also obtained from glycerine by the action of zincic chloride or potassic bisulphate.

IN the *Journal of the Franklin Institute* for April we have the continuation of several papers already commenced, viz.:—Mr. Joseph Harrison's article on the locomotive engine, and Philadelphia's share in its early improvement; of Mr. J. S. Smith's account of the Keokuk and Hamilton Bridge; of Mr. J. F. Henry's paper on the flow of water in rivers and canals; and of Mr. J. Richard's article on wood-working machinery. The only new article of any length is by Lieut. Dutton on the principles of gun construction, and there are the usual paragraphs of Items and Novelties.

THE *American Journal of Science and Arts* for April commences with Prof. Marsh's account of the discovery of additional remains of Pterosauria, with descriptions of several new species, *Pterodactylus occidentalis*, *P. velox*, and *P. ingens*, of which full measurements are given, the last probably measuring nearly 22 feet between the tips of the fully expanded wings.—Prof. A. E. Dolbear describes a new method of measuring the velocity of rotation; and Prof. Dana continues his history of Green Mountain geology, dealing this month with the quartzite.—From Mr. F. B. Meek we have descriptions of two new starfishes and a crinoid from the Cincinnati Group of Ohio and Indiana, which he proposes to name *Palæaster* (?) *Dyeri*, *Stenaster grandis*, and *Glyptocrinus Baeri*.—Prof. Abbe gives an account of his observations on the total eclipse of the sun in 1869; and Prof Twining of various observations on the aurora of Feb. 4.—Mr. Verrill's series of papers include this month recent additions to the molluscan fauna of New England and adjacent waters, with plate.

In the May number is a valuable epitome of recent geographical work in the United States, deduced from the report of the Corps of Engineers, U.S. Army, the route of the Northern Pacific Railroad, and the map of transportation routes in Minnesota and Dakota.—Prof. W. A. Norton contributes a paper on molecular and cosmical physics, in which he propounds several new theorems: the subject is to be continued.—As the commence-

ment of a series of papers entitled "Contributions from the Physical Laboratory of Harvard College," Prof. Trowbridge has a paper on the electro-motive action of liquids separated by membranes.—Prof. Marsh describes, under the name of *Hesperornis regalis*, his exceedingly interesting gigantic fossil swimming bird discovered in the cretaceous strata, which he considers to belong to the Palmipedes, and to be most nearly allied to the Columbidæ, but differing widely in many respects from that group and from all other known birds, recent and extinct. Both in this and the previous number are the usual interesting paragraphs of information arranged under the various natural sciences.

SOCIETIES AND ACADEMIES

London

Zoological Society, May 21.—Mr. R. Hudson, F.R.S., vice-president, in the chair. The Secretary read a report on the additions that had been made to the Society's menagerie during the month of April, amongst which was a young female Baird's tapir (*Tapirus bairdi*) from Nicaragua, and a red-billed flying squirrel (*Pteromys magnificus*) from the Himalayas.—A letter was read from Dr. G. Bennett, of Sydney, N.S.W., giving particulars of the habits of a pair of *Didunculus strigirostris*, and of other birds living in the Botanic Gardens at Sydney. Dr. Bennett also mentioned that a pair of the red-billed curassow (*Crax carunculata*) had built a nest in one of the trees in the same gardens, and had hatched out two young birds, which at the time he wrote were doing well.—Sir Victor Brooke, Bart., read a paper on the royal antelope and allied species of the genus *Nanotragus*.—Mr. A. H. Garrod read some notes on the anatomy of the Huia bird (*Heteralocha gouldi*) as observed in a specimen that had lately died in the Society's gardens, and showed that this form must be referred to the family *Sturnidæ*.—A communication was read from the Rev. J. E. Semper, containing observations on the birds of St. Lucia, to which were added some notes on the species by Mr. P. L. Sclater.—A communication was read from Dr. J. E. Gray on the sea bear of New Zealand (*Arctocephalus cinereus*) and the North Australian sea bear (*Gypsiphoca tropicalis*).—A communication was read from Dr. A. Günther, F.R.S., containing a note on *Hyla punctata* and *Hyla rhodoporus*.—Mr. P. L. Sclater read a paper on the species of Quadrumana collected by Mr. Buckley in Ecuador, amongst which was a specimen of *Ateles fusciceps* Gray, from the western valleys of the Andes.—Dr. Murie read a paper on the osteology of the Tody (*Todus viridis*). He showed that this form comes under the group of *Coccygomorphæ* of Huxley, and does not belong to the Passeres (*Coracomorphæ*). Its nearest allies are the mot-mots and kingfishers, but it must stand as a group of itself (*Todidæ*), notwithstanding which it shows some osteological and other points of resemblance to fly-catchers (*Musicapidæ*).

Linnean Society, May 24.—Anniversary meeting.—The following were elected Officers and Council of the Society for the ensuing year:—President, Mr. G. Bentham, F.R.S.; Treasurer, Mr. W. W. Saunders, F.R.S.; Secretaries, Mr. F. Currey, F.R.S., and Mr. H. T. Stainton, F.R.S.; Council, Mr. A. W. Bennett, Mr. R. Braithwaite, M.D., Mr. G. Busk, F.R.S., Mr. J. Gwyn Jeffreys, F.R.S., Dr. J. D. Hooker, F.R.S., Mr. M. A. Lawson, Mr. H. Lee, Mr. R. McLachlan, Mr. J. Miers, F.R.S., Mr. D. Oliver, F.R.S., and Rev. Thos. Wiltshire.

Photographic Society, May 14.—Mr. James Glaisher, F.R.S., president, in the chair.—A paper "On Photographic Pictures" was read by John Hubbard, in which the manner of elaborating his photographic studies was gone into at some length. His entire method of operating was described, which, however, differed little from that in ordinary use.—Lord Lindsay exhibited a series of transparent pictures of the last eclipse, five positives from every negative being shown, so as to afford an exceedingly clear representation of the phenomenon.—Major Tennant, R.E., also forwarded a series of eclipse pictures for exhibition to the members.

Bristol

Observing Astronomical Society.—*Sun*.—Mr. T. W. Backhouse writes that "there was a fine group of solar spots in the sun's northern hemisphere last month. On the 24th at 5^h there was a largish spot at the preceding end of the group, which on the 23rd, at 3^h, either was small or did not exist at all. On the 26th, about 4^h, its penumbra was 51,500 miles long, and its umbra 28,000, but it never became such a conspicuous umbra as the one which had all along been the largest in the group. On the 28th, at $4^h\ 15^m$, the penumbræ of the two were united, and 88,500 miles long, while at 20^h I found the penumbra to be 92,000 miles in length. It was then so close to the limb that I could not measure it accurately, the height being extremely foreshortened."—*Jupiter*.—Mr. H. W. Hollis, of Newcastle, Staffordshire, reports that on January 14, 9^h, the disc of the planet appeared very sharp, and he counted twenty-two different bands of colour. "Those visible in the equatorial parts of a beautiful, delicate, pinky brown. I am certain that the belts are visible up to the very edges of the disc, but there is an apparent increase of brightness for a considerable distance round the edge of the planet—probably an effect of contrast—which obliterates the extremities of the belts, unless carefully looked for. Several well-marked and beautifully-defined irregularities in the belts showed the rotation most clearly even in half an hour's watching. Jan. 23, $8^h\ 15^m$.—Satellite I. just entered on disc of Jupiter, and appears as an intensely white spot. $9^h\ 20^m$.—Shadow of I. on centre of disc, black, and sharply circular; the satellite itself cannot be seen." Mr. T. W. Backhouse, of Sunderland, observed the transit of Satellite I. on Jan. 14. At $13^h\ 54^m$ it "appeared as a faint white spot." On Feb. 3, $6^h\ 7^m$, he examined Satellite III., and its shadow when in transit. The satellite itself was, at the time mentioned, nearly half across Jupiter, on a darkish belt. "It is much darker than the darkest part of the planet." At $7^h\ 30^m$ it was "still very plain, but only the same shade as the darkest part of Jupiter. It was smaller than its shadow, which was very black." *T. Coronæ Borealis*.—Mr. T. W. Backhouse says:—"A change has taken place in this star. On its fading the second time it became stationary in brightness about the middle of the year 1867, since which time, up the beginning of this year, it continued the same, but with frequent slight fluctuations, which however ceased, so far as I could judge, at the end of 1869. I have suspected fluctuations since 1869, but they were doubtful. On January 14 this year I looked at the star and found it about its usual brightness, or perhaps a little fainter, but certainly not fainter than it had been at times previously. I did not look at it again till March 5, when I found it much fainter than I ever saw it before, perhaps half a magnitude less than usual, and it was the same on the following day." *Nebula in the Pleiades*.—Mr. H. W. Hollis has looked for this nebula with his 8 in. achromatic, but cannot find it. He says:—"There is something peculiar about all the brighter stars of this group, which for months past have appeared to me as if surrounded with nebulous light. Can the nebula have been distributed amongst them?" *Meteors*.—The Rev. S. J. Johnson, of Crediton, witnessed the appearance of "a splendid meteor at $7^h\ 37^m$ April 6. Its course was in a straight line downwards from about 15° above the N.W. horizon to about 5°. Colour, white with a greenish tinge. Duration, about 5″. Seen against a dark sky, this meteor would have equalled, if not exceeded, the brightness of Venus or Jupiter. I was looking for Mercury at the time." On April 19, $11^h\ 10^m$, Mr. William F. Denning, of Bristol, saw a brilliant meteor. It passed slowly down the N.N.E. sky. It was starlike in appearance, and left no train of light. *Mercury*.—The Rev. S. J. Johnson observed Mercury both with the naked eye and telescope on the evenings of March 25 and April 5. A power of 100 on a small telescope brought out the phase.

Cambridge

Philosophical Society, April 29.—Mr. Paley, "On certain effects of Light on Portland Stone." The author said that he doubted from the mode in which this occurred whether the blackness of stone seen in towns was due simply to smoke; the black scraped from the stone was unaffected by soap or solution of soda, and presented under the microscope an appearance quite different from that of ordinary soot.—By Prof. Miller, "On Faye's method of comparing Mètres à Traits, and an improvement of it suggested by Prof. Miller."—By Mr. Bonney, "On certain lithodomous Burrows in the Carboniferous Limestone of Derbyshire." The author said that doubts having been thrown upon the accuracy of his statement of the occurrence of these burrows in Miller's Dale, he had again visited the spot, had found his description correct, and had discovered a large number of these burrows in Miller's Dale and in Tideswell Dale. From the positions in which he found them, he was more than ever convinced they were the work of *Helices*.

May 13.—"On a Method proposed by M. Fizeau for comparing a *mètre à bouts* with a *mètre à traits*," by Prof. Miller.—"On the Section exposed at Roslyn Hill Pit, Ely," by Mr. Bonney. The author stated that there were two hypotheses which accounted for the singular collocation of boulder clay, cretaceous rocks, and Kimmeridge clay in this pit; the one attributing it to a fault, the other to a boulder-like mass of cretaceous beds which had been dropped there in the Boulder clay time. He exhibited plans and sections, and pointed out that the faulting would be of such a singular and exceptional kind that this hypothesis appeared to him in the highest degree improbable. The choice remained between regarding the cretaceous beds as brought on by an ice-raft, or the result of a slip from beds subsequently removed by denudation, and on the whole he preferred the former of these.

EDINBURGH

Royal Society of Edinburgh, May 20.—Prof. Sir Robert Christison, Bart., president, in the chair.—The Keith Prize for the Biennial period ending May 1871 having been awarded by the Council to Prof. James Clerk Maxwell for his paper "On Figures, Frames, and Diagrams of Forces," which has been published in the Transactions, the medal was delivered to him by the President at the commencement of the meeting.—The Neill Prize for the Triennial period ending 1871 has been awarded by the Council to Prof. Turner for his papers "On the Great Finner Whale," and "On the Gravid Uterus and the Arrangement of the Fœtal Membranes in the Cetacea," which have been published in the Transactions.—The following communications were read:—"Some Helps to the Study of Scoto-Celtic Philology," by the Hon. Lord Neaves, V.P.—"Some Observations on the Dentition of the Narwhal (*Monodon monoceros*)," by Prof. Turner.—"On the Occurrence of *Ziphius cavirostris*, got from Hillswick, Shetland, in the Shetland Seas, and a comparison of its cranium with that of *Mesoplodon Sowerbyi*," by Prof. Turner.—"On the Maternal Sinus System of the Human Placenta," by Prof. Turner.

HALIFAX, NOVA SCOTIA

Institute of Natural Science, December 11, 1871.—The vice-president, Dr. Gilpin, in the chair. The vice-president read the concluding paper of a series on the mammals of Nova Scotia, including the moose deer. Dr. Gilpin described its peculiar form, differing from all mammals by the length of its cannon bones (metacarpal and metatarsal), whilst in the shortness of its neck, its great height, its prehensile lip, it had a singular analogy with the equatorial form of the elephant, the giraffe, and the tapir, yet it more resembled certain large wading birds. It might be called a wading mammal, in summer resorting to the swamps and shallow lakes, in winter its long cannon bones allowing it to walk in the deep snow. It thus becomes straddling and weak-footed. In comparing its hind leg with that of the greyhound and hare, the swiftest animals known, its form would be found exactly opposite. He described its nuptial suit in September (its rutting season) of glossy black, and golden tan legs, and its wintery livery of shaggy grey hair. Its identity with the elk of Sweden was discussed, and from observations in the R. C. Surgeons' Museum, Sir John Richardson, and especially from Captain Hardy, R.A., who compared his sketches, notes, and measurements, of the moose of Nova Scotia, personally, with a pair of young elks from Sweden at Sandringham, Dr. Gilpin concluded them to be identical. Allowing them to be identical, then, as their fossil bones have been found in the Upper Tertiary formations in America, and not yet in the Old World, the moose must be held as the primitive type. Dr. Gilpin thought that, with the carriboo, its form must have existed contemporarily with many forms now extinct; that, perhaps, it was one of the earliest existing fauna that succeeded the glacial epoch in Nova Scotia, and that from some cause now existing this earliest fauna may be destined to be the last. From the almost entire identity of the boreal marine fauna, the marine birds, and the fish, the more we study the arctic forms, the more we are impressed with the conviction that we must look to the north for the common type of many of our temperate and equatorial forms. The shaggy elephant of Lorna, and the rough musk ox of the Pole, and the hairy-coated carriboo, may each have been the primal type of the naked-skinned elephants and buffalos of Asia and the satin-skinned African deer, whilst the coatis may equally have been the type of all foxes and dogs to the hairless race in Turkey. In a conversation that ensued it was maintained that two varieties existed in the province, but Dr. Gilpin considered them not permanent varieties. To show the numbers still extant, the game book of a gentleman present gave, from the year 1863, twenty-seven, whose death he had been in at, and ninety-seven which he had seen altogether.

CALIFORNIA

Academy of Sciences, San Francisco, November 6, 1871.—Dr. T. Blake, president, in the chair.—Mr. Harford stated that he had examined some Indian graves on San Miguel island, from two of which he had obtained a number of relics. The pits were about 25 ft. long, 5 ft. deep, and situated at an elevation of about 80 ft. above the sea. In one of the pits there were from 75 to 100 skeletons, most of the skulls showing marks of violence. No order had been observed in the burial, children and adults, male and female, all lying together. The other pit seemed to be of a much older date, as the bones were in a more advanced state of decay, and only stone beads or trinkets were found there, whereas in the other principally glass and shell beads were found. Large shell heaps were of common occurrence on the island, showing that at one time they must have been inhabited, although no Indians had been known to live on the island since the settlement of the country by the Spaniards. Prof. Davidson, of the United States Coast Survey, remarked that as a rule in the entrances to the harbours and rivers on our coast the channels all tended to the N.W., tne northern headlands showing bold rocky bluffs, the southern points, on the other hand, forming long low sandy beaches. He said his own observations had been confirmed by information received from Lower California, thus showing that there is a strong inshore northerly current along the entire coast.

December 4.—The president, Dr. Blake, in the chair. Prof. Whitney exhibited a collection of fossils made by Mr. J. E. Clayton in Nevada, near the 116th meridian, and not far from the mining settlement of Eureka. These fossils are very interesting as representing the Primordial or Potsdam period of the Silurian, and exhibiting the same combination of genera and species of the *Lingulidæ* family of the brachiopods, and the *Paradoxidæ* family of trilobites, which is so characteristic of this group farther east. Indeed there are no families represented in these specimens but these two. The trilobites are very imperfect, much broken, and crowded together in great numbers in the rocks. The same *Agraulos* (*Arionellus* of Barrande, and *Crepicephalus* of D. Owen, Meek, and Hayden), which occurs in the Big Horn Mountains, about longitude 167°, is found in this lot from the 116th meridian. There is also a *Conocoryphe* (Conocephalites); but the *Agraulos* is much the most abundant. The brachiopods appear to be represented by at least two genera, *Lingulepis* (Lingula) and *Obalella*. The lithological character of the rock in which these fossils occur is of importance, as it is not a sandstone, but a limestone. The Primordial or "Potsdam sandstone" fossils have not, previously to this discovery, been found to the west of the Big Horn mountains, so far as appears from any published documents. The discovery is therefore an interesting one, and will furnish a valuable datum-point for working out the geology of the Great Basin.—Mr. Montrange read a paper on White Island on the coast of New Zealand. Whakari, as the Maoris call it, is White Island, is situated in the Bay of Plenty, on the east coast of New Zealand (North Island). Hours before reaching it, one sees the large crest of vapour which crowns its summit. It is of very difficult access, and very few even of the oldest settlers have ever visited it. The whole of the island is one perpetually active crater, which, like the mollusc that secretes its little shell, has built up its huge cone, three and a half miles in circumference at the base, 860 feet high, of scoriæ and indurated ashes. The walls of the cone are straight, cut at intervals with deep longitudinal furrows; the crater is inside, on the eastern side.—Prof. Marsh, of Yale College, who was present at the request of the President, made some remarks on the results of his trip from Nebraska and Dacota across the continent to Eastern Oregon. He stated that the extensive fresh water deposits that had been found in Nebraska and Dacota were again met with in Eastern Oregon, extending, in fact, across the continent. The Oregon beds were as rich in new and interesting fossil remains as these on the eastern sides of the Rocky Mountains. During his trip across the continent, he had selected a large number of vertebrates, amongst which were thirty or forty species, which he considered entirely new. The family *Equidæ* were represented by several new species, furnishing important material for tracing the

development of the group through its intermediate forms. Another interesting fact in connection with these fresh water deposits is, that whilst the fossil fauna of Eastern Oregon abounds in species identical or analogous with those of Nebraska and Dacota, yet extensive fresh water deposits were met with in Wyoming and the centre of the continent in which the fossil fauna was of an entirely distinct character, although belonging to the same geological epoch, the Miocene.

Paris

Academy of Sciences, May 13.—M. Chasles presented a further series of theorems relating to the theory of the obliques of a curve—M. L. Cailletet communicated a note on the influence of pressure upon the bands of the spectrum, in which he describes the increased resistance offered by compressed gases to the passage of the electric spark and its influence on the luminous phenomena produced, and stated that whilst the luminous intensity of the bands of the spectrum is increased by pressure, when the latter is extreme they disappear entirely, the spectrum becoming continuous.—M. Melsens forwarded a memoir on lightning conductors with multiple conductors; and M. Decharme a note on the spontaneous ascensional movement of liquids in capillary tubes, compared with the flow of the same liquids in the same tubes under a constant artificial pressure.—A note was read by M. Arnould Thenard on the decomposition of carbonic acid under the influence of electricity.—M. Balard presented a note by M. Amagat on the dilatation of moist gases.—M. Lamy commented on a recent note by M. Personne on the presence of selenium in sulphuric acid of French manufacture, and indicated that its existence had been known for the last ten years.—M. Wurtz also presented a note by M. Scheurer-Kestner upon the same subject.—A note was read by M. J. Boussingault on the determination of carbon combined with meteoric iron.—M. C. Robin communicated a note by M. H. Byasson on the hydrosulphate of chloral (sulphuretted chloral).—M. Bouchut presented some investigations on the action of the bases and alkaloids obtained from opium.—M. Robin presented a note by M. J. P. Megnin, on the development of the unarmed cestoid worms, in which he described his observations on an undetermined species allied to *Tænia perfoliata* (Goeze), *T. plicata* (Rud.), and *T. mamillaria* (Mehlis), discovered by M. Baillet and himself in the horse and mule. He seems to think that all the stages of development of this parasite are passed in the same animal.—M. Clos presented a note upon a portion of the leaf in certain plants, to which he gives the name of *prelimb*.—The Minister of Foreign Affairs communicated a report received from the French Consul-General at San Francisco, relating to an earthquake which occurred in the county of Inyo on March 30.—A note on the silicified plants of Autun, with observations on the structure of *Dictyoxylon*, by M. B. Rénault, was presented by M. Brongniart.—A letter from M. Palmieri on the late eruption of Mount Vesuvius, dated May 5, was read.

Vienna

Academy of Sciences, January 4.—Prof. L. Gegenbauer, of Krems, forwarded a second memoir on the evaluation of definite integrals.—Dr. F. C. Schneider noticed the production of a detonating iodine-compound by treating oxyiodide of mercury with solution of iodide of potassium containing iodine. The detonating compound was formed as a crust over the residue of oxyiodide and upon the sides of the glass in which the mixture had remained for a fortnight; its violently explosive qualities were discovered on an attempt being made to remove it by means of a glass rod.—M. J. Schlesinger deposited a sealed note on the formula for the rapidity of outflow of water from tubes. — Prof. von Oppolzer announced the re-discovery on December 20, 1871, of the lost planet Ægina (91).—Dr. Sigmund Exner presented a memoir entitled "Further Investigations on the Structure of the Olfactory Mucous Membrane in the Vertebrata," in which he showed that the branches of the olfactory nerve in birds, mammals, and in man, terminate in the same way as was previously described by him in the frog. The author regarded the glands of the olfactory region as tubular, and not acinose.—Dr. A. Boué communicated a reply to M. Blaek's remarks on his catalogue of northern and southern lights, and M. H. Fritz forwarded a note relating to the same subject.

January 11.—Dr. L. J. Fitzinger communicated a memoir on the natural family of the Pangolins (*Manes*), and M. S. Adler some mathematical demonstrations connected with the game of dominoes.

January 18.—A memoir by D. A. Seydler on the path of Dione (106) was read.—Dr. F. O. Sofka communicated six short papers on various mathematical and physical subjects.

BOOKS RECEIVED

English.—Introduction to the Study of Palæontological Botany: J. H. Balfour (A. and C. Black).—Fruit Trees, 2nd edition: W. Wardle (Lockwoods).—Nature: A. Walker (Longmans).—The Fallacies of Darwinism: C. R. Bree, M.D. (Longmans.)

American.—Annual Record of Science and Industry for 1871, edited by S. F. Baird.—The Lens, edited by S. A. Briggs, vol. i., No. 2.

DIARY

THURSDAY, May 30.

Royal Society, at 8.30.—The Bakerian Lecture: On the Structure and Development of the Skull of the Salmon: W. K. Parker, F.R.S.—On Ammonia in the Urine in Health and Disease: Dr. Tidy and Dr. Woodman.—The Structure and Functions of the Rods of the Cochlea: Dr. Pritchard. Examination of the Gases occluded in Meteoric Iron from Virginia: Dr. J. W. Mallet.

Society of Antiquaries, at 8.30.—Ballot for the Election of Fellows.

FRIDAY, May 31.

Royal Institution, at 3.—Old and New Art: E. J. Poynter.

SATURDAY, June 1.

Royal Institution, at 3.—On the Chemical Action of Light: Prof. Roscoe, F.R.S.

Government School of Mines, at 8.—On Geology: Dr. Cobbold, F.R.S.

MONDAY, June 3.

Royal Institution, at 2.

Entomological Society, at 7.

Anthropological Society, at 8.—On the Artificial Enlargement of the Earlobe in the East: J. Park Harrison, M.A.—On the Westerly Drifting of Nomads—the Fins: H. H. Howorth, M.A.—On Tumuli at Sapolia, Russia: Baron de Bognschefoky.

Victoria Institute, at 8, Anniversary Meeting.

TUESDAY, June 4.

Royal Institution, at 3.—On Development of Belief and Custom E. B. Tylor, F.R.S.

Zoological Society, at 9.—On Dinornis (Part XIX.) containing a description of a Femur, indicative of a new genus of large wingless bird (*Dromornis australis*, Owen) from a post-tertiary deposit in Queensland, Australia: Prof. Owen, F.R.S.—On the Anatomy of the Two-spotted Paradoxure (*Nandinia binotata*): Prof. Flower.

Society of Biblical Archæology, at 8.30—On the Political Condition of Egypt before the Reign of Rameses III.: Dr. August Eisenlohr.—Some Mathematical Observations on the Dimensions of the Base of the Great Pyramid, and the Royal Coffer: Solomon M. Drach.—The XXXVII. Aamu in the Tomb of Chnum-Hotep, at Beni Hassan, identified with the Family of Israel: Daniel H. Haigh.

WEDNESDAY, June 5.

Geological Society, at 8.—Notes on Sand-pits, Mud Volcanoes, and Brine-pits, met with during the Yarkand Expedition of 1870: Dr. G. Henderson.—On the Cervidæ of the Forest-bed of Norfolk and Suffolk: W. Boyd Dawkins, F.R.S.—The Classification of the Pleistocene Strata of Britain and the Continent by means of the Mammalia: W. Boyd Dawkins, F.R.S.

Microscopical Society, at 8.—Remarks on the Homological Position of the members constituting the Thecated Section of the Rotatoria: Chas. Cubitt.—On a Micro-pantograph: Isaac Roberts.

THURSDAY, June 6.

Royal Institution, at 3—On Heat and Light: Prof. Tyndall, F.R.S.

Society of Antiquaries, at 8.30.

Linnean Society, at 8.

Chemical Society, at 8.

CONTENTS

THURSDAY, JUNE 6, 1872

BAD GREEK OR GOOD GERMAN?

AN event occurred on Thursday last at Cambridge, not in itself, perhaps, of imposing magnitude, but yet fraught with very important consequences. For this long while back an agitation has been going on with the purpose of making Greek no longer absolutely essential to the Previous Examination (or "Little Go," as it is popularly called), but of allowing French or German, or both, to be substituted for it at the option of the candidate. As any long-headed man might have foreseen, the genuine scholarship and liberal intelligence of the University are in favour of such a change; but the opposition has been neither feeble nor silent. Discussion has abounded more and more, and "fly-sheets" have fallen like the latter rain. The advocates of the change seem to have been more or less governed by a dislike to many words, and to have had large faith in the merits of their cause; their opponents, on the other hand, appear to have believed in the efficacy of much speaking, and in the effects of arguments drawn from all quarters, and looking all ways; their papers and speeches, all put together, form as pretty a piece of incoherence as may be found in a literary day's march, and would have been a perfect godsend to the great Skepsius when he wrote his famous tract *An hominibus mens absit*. The reasons indeed for making the change were so clear and cogent that there seemed hardly any hope of its being accomplished. Yet by one of those freaks of fortune which are met with even in the Universities, wisdom prevailed; and by the vote of the Senate on Thursday last, which will, in all probability, be speedily ratified at a second meeting, the student who desires to go out in an "honours" examination henceforth need not at his Little Go scratch up a smattering of bad Greek, if he satisfies his examiner that he possesses a real knowledge of French or German.

We trust that the scientific workers at Cambridge will take heart at this happy issue of the struggle, and gird up their loins for the heavy task of introducing order and system into the chaos in which the natural science studies at Cambridge are now lost. Let them set to work at once, and no longer wait for that *Deus ex machina* of the Royal Commission, who at present sit aloft, like the gods in Tennyson's "Lotos Eaters," and of whom it might be said, "Though their wheels are grinding finely, yet they grind exceeding slow."

The graduates of the University of London too might do well to ponder over this result. It is one of the marks of good tone at Cambridge to be very imperfectly acquainted with the Metropolitan University, except so far as its scholarships and examinerships are concerned; and accordingly it was stated more than once in the course of the discussion, and used as an argument against the proposed change, that the University of London had recently refused to make Greek optional at its Matriculation Examination. Our better informed readers are probably aware that the Senate, the real governing body of the University, have the matter at this very moment under their consideration, and, without wishing to forestall the future, we may presume to say that beyond doubt a change will soon be made. It is perfectly true that Convocation, in spite of the Report of its Annual Committee, hesitated to recommend the change; and this seems to have led to the mistake of the Cambridge advocates of bad Greek; but it is well known that, as indeed a sound knowledge of human nature would lead one to expect would be the case, there is among the body of graduates of the radical University, a mass of partly rabid and partly stupid conservatism, which, if it had its own way, would soon bring the University to ruin. Happily the executive Senate, being for the most part selected by the Crown, is wise and liberal, and is especially animated by the feeling that the University, if it is to fulfil its function, must grow with the growth of time, and change with changing things.

It is not a little to the credit of the older University of Cambridge that she should have been actually the first to remove one more of the old-fashioned swaddling clothes, which have been checking the development of youthful science, and we trust it is an earnest of still greater changes which she means to take in hand. Science has been too long at that old University a sort of blind Samson, bound with many cords, and serving chiefly to make sport for mocking Philistines of the classical and mathematical tribes. It is time his cords were loosed, and his strength made use of for the general advancement of the University.

OUR NATIONAL INDUSTRIES

IT is believed by many scientific men that research is all but dead in England. Whether we confess it or not, England, so far as the advancement of knowledge goes, is but a third or fourth-rate power. It is not our present purpose to inquire into the causes of all this; whether, as some say, it is because our professors are so rich, or whether, as others affirm, because all arrangements for the increase of knowledge are so poor, but rather to call attention to the certain influence of this on the wealth—let us put it in the most sordid manner—of the nation in the future.

In this inquiry we find to our hand, in a recent number of the *Birmingham Morning News*, an article on the future extension of Birmingham industries, by Mr. George Gore, whose important researches are well known. We know no one better qualified than Mr. Gore to discuss the subject, and no town where it is more important that the subject should be ventilated, for Birmingham has received much from and has given nothing to original scientific research; but the conclusions to be drawn from the article are in no way limited to Birmingham.

In this article Mr. Gore first considers by what general means the chief trades of Birmingham were first originated and improved; and then discusses whether we can by similar means, applied in a more effectual manner, lay the foundation of other new trades and improvements. Mr. Gore writes:—

"Let us consider German-silver and its manufacture. That substance is an alloy of copper, zinc, and nickel; it owes its peculiar whiteness or 'silver-like' appearance to the latter metal, and cannot be made without it; it is certain, therefore, that by whatever means

that metal or the alloy was discovered, the discovery was the origin of the German-silver manufacture, and was essential to all manufactures, processes, or appliances, in which German-silver, nickel, or any of its compounds are used. Nickel was discovered by Cronstedt during the year 1751, and its compounds were chiefly investigated by English and foreign chemists. Cronstedt found it as a peculiar metal in the mineral called kupfernickel, whilst chemically examining the properties of that substance. The general method by which he discovered it was careful experiment, observation, and study of the properties of matter. I believe it is a fact that the Chinese and other nations made alloys of nickel long before nickel itself was known to be a separate metal; they had found, by experiment, that when ores of copper and zinc were mixed with a particular kind of mineral and smelted, a white alloy was obtained; but this also proves the general statement already made, that the German-silver manufacture was originated by means of experiment and observation. It was by a more skilful, but similar mode of procedure, that Cronstedt discovered the metal itself, and thus laid the basis of improvements in the manufacture of its alloys. I need not here enlarge upon the multitude of uses to which nickel has already been applied in Birmingham manufactures, nor speak of the large sums of money which have been and still are made by means of it and its compounds. . . .

"The manufactures of iron-wire and copper-wire for telegraphs are two other modern trades of great magnitude in this town, and were originated in the following manner:—In 1799, Volta, an Italian philosopher, was experimenting, observing, and studying the electric properties of metals in liquids, and discovered the Voltaic battery. In 1815, Prof. Oersted, of Copenhagen, was experimenting on the relation of electric currents to magnets, and observed that when a magnet was suspended near and parallel to a horizontal copper-wire, through which an electric current was passing, the magnet moved spontaneously, and placed itself at right angles to the wire. From these two small experiments, made by putting matter and its forces under new conditions, observing and studying the results, all our telegraphs and the immense manufactures of iron and copper telegraph wire have arisen.

"There is a saying, that 'all great things have had small beginnings,' and this is true, not only of electric telegraphs, but also of the great trade of electro-plating, and of the magneto-electric machine, which is now largely used instead of the Voltaic battery. After Volta had made his small and apparently unimportant experiments on the electricity produced by metals and liquids, various persons tried the effect of that electricity upon metallic solutions. Brugnatelli, in 1805, found that two silver medals became gilded in a solution of gold by passing the electricity through them. Mr. Henry Bessemer, in 1834, coated various lead ornaments with copper by using a solution of copper in a similar manner. And in 1836 Mr. De la Rue found that copies might be taken in copper of engraved copper plates by the electro-depositing process. Faraday discovered magneto-electricity in the year 1831, by rotating a disc of copper between the poles of a magnet, and he has stated that the first successful result he obtained was so small that he could hardly detect it. This simple experiment was the origin of the magneto-electric machine, and many of those machines are now used by Messrs. Elkington for depositing copper, silver, and gold, instead of the Voltaic battery.

"Another large manufacture of this district is that of phosphorus. The origin of it is due to the man, whoever he was, who first isolated that element. Histories of chemistry tell us that it was discovered by Brandt, a merchant of Hamburgh, in 1669; but evidence exists that it had been obtained in the separate state very many years before by the early Arabian chemists. Brandt obtained it by distilling a mixture of dried residue of urine and charcoal. His discovery was also made by careful experiments, and observation of the properties of matter, and had it not been made there would have been no manufactures of phosphorus or phosphorus matches in this district.

"Priestley made many experiments on the absorption of gases by water, and proposed such liquids as beverages, and those apparently trifling experiments have since expanded into the large manufactures of aërated waters."

After having given these instances out of many, the manner in which these practical results have been obtained is stated:—

"Persons inexperienced in scientific matters are apt to think that discoveries are generally made by accident. The reverse is, however, the case; nearly all our great modern discoveries were effected by men who were constantly making careful experiments upon the properties of matter and its forces, by subjecting them to new and definite conditions. Nearly all persons look upon such discoveries as fortunate ideas, which, when once found, are quickly developed, instead of which they are in most cases, slowly developed results of most difficult mental labour. Discoveries in science are occasionally made, not by original scientific investigators, but by practical men engaged in manufacturing or technical employments. The hydro-electric machine originated in this way: a man at Newcastle was attending to a steam-boiler, and found that he received electric shocks when he touched the boiler. This circumstance was investigated by his employer, Mr., now Sir William, Armstrong, and led him to construct the hydro-electric machine. The accumulation of electricity in submarine telegraph cables was also first observed at the Gutta-Percha Company's works, London. It was noticed on testing the cable by means of a voltaic battery (the cable being submerged in water) that discharges of electricity flowed from the cable after the battery was removed; this circumstance was investigated by Faraday, and led to improvements in submarine telegraphy. In these instances also the same general method was employed, viz., new experiments were made (though not intentionally) by putting matter and its forces under new conditions, and new results were observed. . .

"Scientific discovery, therefore, by developing new facts and laws relating to matter and its forces, constitutes not only the basis of new manufactures, but largely, also, of the improvements in trades made by inventors and practical men; and if discoveries are not made, the means by which improvements are effected by such men will become exhausted. The great value of new scientific knowledge to such men is proved by the fact that when new scientific discoveries are published there are numerous inventors and practical men who immediately endeavour to apply them to useful purposes. Since the first application of coal-tar to the production of dyes, every discovery in that branch of chemistry has been closely watched for a similar purpose.

"According to all our experience, scientific discovery provides the knowledge necessary for making inventions, and practical inventions lead to increase of trade. It might easily be shown that in this way scientific research has already resulted in the employment of whole armies of workmen, and in the expenditure and investment of a fabulous amount of money in railways, telegraphs, machinery, gasworks, chemical works, electro-plating, photography, &c., &c., in this country; and Birmingham has received a large share of the benefit."

We now come to the point that we are anxious to enforce:—

"The future success of this town and district is dependent upon original scientific research to a degree of which persons in general can form but little conception. Hun-

dreds of millions of pounds are being expended in covering the earth with telegraphs, and thousands of millions in covering it with railways, gasworks, waterworks, &c., and Birmingham and its district has its share in supplying the rails, the wire, and the machinery. In this country alone more than 550,000,000 of pounds have been already expended upon railways only. *Original scientific research is the great fountain-head of industry*, and its capability of developing increased trade is practically unlimited: it is at present quite in its infancy, and we are only on the very threshold of a knowledge of the forces of nature, and of the constitution of material substances; and if such enormous results are being produced by the beginnings of unaided science, what may be expected from its future developments, especially if scientific research is assisted in an effectual manner?

"Numerous important subjects of investigation, capable of yielding valuable results bearing upon the trades of this town, exist in all directions. Researches in electricity and in inorganic chemistry, particularly the metals and their compounds, would probably lead, as they have done before, to the establishment of new trades, and to improvements in local manufactures, and thus lay the foundation of future commercial prosperity. Discoveries in science, however, are best made, not by trying to obtain some valuable commercial or technical result (that object belongs to an inventor), but by making new, reliable, and systematic investigations. By investigating the chemical action of electricity upon saline bodies, Sir Humphry Davy isolated sodium and magesium, which has led to the recent establishment in Manchester of the manufactures of those metals. By the abstract researches of Hofmann and others upon coal-tar, the immensely profitable manufacture of the splendid coal-tar dyes was originated.

"Scientific discovery is the most valuable in its ultimate practical results when it is pursued from a love of truth as the ruling motive, and any attempt to make it more directly and quickly remunerative, by trying to direct it into practical channels, will decrease the importance of its results, diminish the spirit of inquiry, and sooner or later reduce it to the character of invention. The greatest practical realities of this age had their origin, not in invention or a search for utilities, but in a search after important new truths, entirely irrespective of what utilities they might lead to.

"I do not intend by these remarks to imply that any new trades or improvements in manufactures have been or can be effected without the labours of inventors and practical men; but that there should be a more judicious division of labour, one man to discover new truths, another to put them into the form of practical inventions, and the practical business man to work them; because it is proved by experience that in nearly all cases these different kinds of labour require men of widely different habits of mind, and that the faculties of discovery, invention, and practical manufacture, are very rarely united in one man.

"Our large manufacturers and men of business have accepted and employed the advantages of science in an endless number of ways in their occupations, and have thereby acquired great wealth; but, notwithstanding this, and that the greatest trades of this district were originated and improved largely by means of scientific investigation, scarcely any of the wealthy manufacturers or landholders of the locality, who have derived such great benefits from the increase of trades, give the least assistance to scientific research; that which is the duty of all has been attended to by none. The probable explanation is, original scientific research is a subject quite outside the experience and knowledge of persons in general. It may be objected that such research is not aided, because it sometimes takes a long time to acquire a practical shape and make it pay. We do not omit to plant an acorn because it requires many years to become an oak; we do not neglect to rear a child because he may not live to become a man; but we leave scientific discovery to take care of itself."

England's present and special weakness is then referred to:—

"Our practice with regard to science is very different from the plan carried out in Germany. Within the last few years great laboratories have been erected in Berlin, Leipzig, Aix la Chapelle, Bonn, Carlsruhe, Stuttgardt, Griefswald, and other places, at the expense of the State, and special provision has been made in them for original scientific research. A glance at the frequently published list of scientific investigations made in different countries will show us that the Germans are making a far greater number of discoveries in science than ourselves. If we are to maintain our position as a manufacturing nation, we also must adopt special means to promote scientific research; for how can we expect to obtain new arts and manufactures, or improvements in old ones, if we do not make new discoveries in the properties of matter and its forces? I need not multiply instances of the essential dependence of our present commercial success upon abstract scientific research, but may safely affirm that nearly all our great manufactures have been originated by means of experiment, observation, and study of matter and its forces; and that the great bulk of the improvements made in manufactures by practical men could not have been effected had not scientific investigators discovered, and made known in books, the properties of bodies. The inference from these conclusions is obvious: by adopting similar means, but in a more effectual way, we shall obtain similar but more successful results."

And this being so, what is the actual condition of things? According to Mr. Gore, "at present, original scientific researches are generally made by teachers of science, who spend a portion of their scanty incomes in making experiments, and lead lives of great self-denial in the labour. There is absolutely no provision in this country for the support of scientific investigators, and thus the great source of new trades and improvements in manufactures remains undeveloped."

Surely if scientific men are convinced, first, that the future of our national industries depends upon research, and secondly, that there is no research, the time has arrived when action of some sort is incumbent upon them if they are ever to take action in any subject whatever: for it is perfectly obvious that any bettering of such a state of things can only proceed from the action of the scientific men themselves.

We have let Mr. Gore speak for himself thus at length, as in his article there is ample endorsement of much that has already appeared in this journal, but he is by no means the only witness that we can appeal to. Even the President of the Chemical Society is compelled to acknowledge that the original researches brought before that Society have fallen nearly to zero. Commenting on this, the *British Medical Journal* points out that the institutions which were formerly considered the homes of research, are now silent. If these things be true, then if those who hold that research is a national necessity are right, our future position is not far to seek.

THE HIGHLANDS OF CENTRAL INDIA

The Highlands of Central India. By Captain J. Forsyth, Bengal Staff Corps. (London: Chapman and Hall.)

THIS is a book descriptive of that great tract of hill and forest country which is situated in the very centre of the Indian Peninsula, and whose drainage forms

the headwaters of the Narbadá, the Tapti, the Sône, and affluents of the Mâhânadi.

The author, who, in the course of his professional duties, acquired a close and intimate acquaintance with the country and its inhabitants, commences by giving a sketch of the probable history of the various races found in this wild and, until lately, almost unexplored country—races whose ethnological and religious history possess peculiar interest; because here the Aboriginal tribes, the races of mixed Aryan and Aboriginal blood, and the Hindoos proper, can be found living side by side; and the effects of the colonisation of the district by the Aryans of Hindustan can be traced out with some degree of clearness.

A considerable portion of the book is devoted to the author's sporting experiences. These he relates in a lively and spirited style; but as the reminiscences of Indian sportsmen have a strong family likeness, this part of the book does not call for much notice, except that the author appears to make rather too light of the danger of bison-shooting, and makes some statements concerning this game which are scarcely correct, one of these statements being that the animal is always known under the name of *bhînsa*, or more correctly *bhainsa* (a word resembling in sound the English word bison), and never as *gaur*. Now in the very district of Northern Belâspùr which the author describes in the latter portion of the book, there is a high and prominent hill much frequented by these animals, and called in consequence Gaur-duàri, or the pass of the bison. The author also appears to confound the bison of Central India with the similar but not identical animal, known as the Mithan or Mithna, found on the hill ranges of Eastern and North-Eastern Bengal.

From the description given of some of the shrines and pilgrimages met with in these hill districts, an idea may be formed of the way in which the Hinduism of Hindustan proper has been localised; and how the scenes of some of the principal events of Hindu mythology have been transferred from the Ganges and Jumna to the Narbada and its adjacent heights.

The latter portion of the volume is devoted in a great measure to the country lying under and east of the Mykul range; that is the range which, according to the author's definition, forms the eastern boundary of the Highlands of Central India. This tract of country is remarkable, because it presents, perhaps, the greatest sweep of unbroken jungle and forest to be found in India south of the Ganges and Brahmaputra. It is neither plain nor hill, but rocky with gentle undulations, and covered with forest. Only a few miserable villages are found throughout the whole country; just enough to make its wildness and desolation more striking. Such a country, unfitted by nature for cultivation, and exhaling a deadly malaria, must long remain the home of the elephant, the tiger, and of the animals on which the latter preys; nor are there found any remains or traditions which would indicate that the place had ever been more thickly populated than it is at present. Here man is the inferior animal, and the wild elephant is the lord of the country. He roams at will from place to place, and, just when the unhappy villager looks to gather in his scanty rice crop, wrung with difficulty out of an unwilling soil, he invades the fields and browses at leisure on the ripening grain, utterly scorning the feeble efforts of the hapless owner to drive him away. Probably no European has braved the deadly malaria of the country at the time of the ripening of the rice crop, or that of the drying up of the rains, but the deep and enormous foot-prints imprinted in almost every field by this jungle ravager remain visible throughout the dry season, and tell the tale of spoliation only too plainly.

Throughout this district, and indeed with most of the tribes who inhabit the wilder and more remote parts of Central India, such religion as the people possess is "devil" worship and fetishism, with just so much gloss of Hinduism as may be imparted by a rare visit to a Hindu shrine, or the presence of a brahmin whenever anything is to be got—which is seldom.

A Gond legend, taken down from the lips of one of their most celebrated bards, and translated by the author into blank verse, in imitation of Longfellow's "Song of Hiawatha," is given at length; it is interesting because it brings in here and there some curious little bits of savage life, and also from the very strong resemblance of the whole legend to that on which Longfellow's poem is based. Moreover, as the author points out, a still more curious analogy will suggest itself to the careful reader.

The whole work is written in a very lively and readable style. It will be found amusing by those fond of sporting anecdotes; and though the subjects may be thought to have an interest too local for the general reader, yet the spectacle here presented of races of men just emerging from utter barbarism, and acquiring the rudiments of civilisation, gives to the country and its inhabitants an interest which it would not otherwise possess.

M. T. SALE

OUR BOOK SHELF

Lecture Notes for Chemical Students.—Vol. II. Organic Chemistry. By E. Frankland, D.C.L., F.R.S. (London: John Van Voorst.)

IN this, the second part of "Lecture Notes for Chemical Students," Dr. Frankland develops very fully his own peculiar notation. The use of thick letters, as $\mathbf{C}\,H_4$; of contracted symbols for many organic radicles, as Ayo for $C_5H_{11}O$; of a peculiar way of writing the formulæ of well-known substances, so as at first sight to make them appear as if they were new compounds, as $\mathbf{N}PhO_2$, representing nitrobenzol; these and a few other remarkable characteristics will make this book, we should think, seem rather startling to the ordinary student. By combining attendance on lectures on organic chemistry with careful reading and a good deal of patient work, the student will find these "Lecture Notes" very useful, containing as they do, in small space, the results of the latest investigations as these bear upon the molecular constitution of organic compounds. Very large use is made of graphic formulæ, and also of the theory of types. The types used are somewhat different from those with which we are familiar in the text-books, and certainly the names applied to them are derived more from an anatomical than a chemical vocabulary; thus, the marsh gas type is termed the "Monadelphic," the methyl type the "Diadelphic," and so on. The very useful and scientific method of writing the formulæ of all organic acids, as containing the group COHO; all alcohols, as containing CH_2HO; and all aldehydes, as containing COH, is adopted throughout. The relations of alcohols, aldehydes, and

acids; the passage from one class of alcohols, &c., to another; and very many other points of great scientific value, too commonly overlooked in the text-books, are here all carefully noted. As we said, the book requires attentive study, but this it will certainly repay.

M.M.P.M.

Thermal Paths to the Pole. An Address delivered before the St. Louis Mercantile Library Association in January 1872. By Silas Bent.

In this pamphlet the author repeats the substance of a lecture delivered in 1868, the object of which was to show that the continuations of the warm Gulf Stream of the Atlantic, and of the Japan current in the Pacific, afford the only practicable avenues by which ships can enter an assumed open sea round the North Pole; and points out how the more recent Arctic explorations have confirmed the views then advanced.

The author's opinions should derive weight from the fact that he was one of the leading scientific observers in the American expedition of 1852, during which the Japan current was mapped out, and from his twenty-five years of observations at sea.

So far as the warm drift continuing the Gulf Stream into the Arctic region between Spitzbergen and Nova Zemlia is concerned, the theory of its influence (which, however, can hardly be called "original," since it has been current among Arctic authorities for many years) has indeed been remarkably confirmed in the past year by Payer and Weyprecht's voyage in open water to 79° N. lat. But it remains to be shown that the summer current from the Pacific through the narrow and shallow passage of Behring Straits has any considerable influence on the condition of the Arctic basin. In the circumpolar chart which accompanies the pamphlet, Behring Straits has been carefully widened to admit the Kuro-Siwo in a breadth quite equivalent to that of the Gulf Stream drift.

A considerable portion of the address is devoted to the description of a method by which "were it not for the inhumanity of exercising such a power," the whole of Europe might be placed at the mercy of America. Europe derives its mild climate from the Gulf Stream, and to divert this stream from its present direction would be to make "Europe a frozen wilderness." This grand result, the author believes, could be accomplished "by the possession of the Isthmus of Panama and the expenditure of half the cost of the recent war between France and Germany, in the excavation of a sufficient width and depth of the rock only that intervenes between the Caribbean Sea and the Pacific." Mr. Bent has himself, however, thrown some doubt on the entire practicability of his design by quoting, in a previous paragraph, the belief expressed by Professor Maury that the great mass of the Gulf Stream is formed by that part of the equatorial current of the Atlantic which passes to northward of the Antilles, and which "must be a hundred-fold greater than that which returns to the east from the Gulf of Mexico;" he has also omitted to notice that the force of the drift in the Caribbean Sea is not directed in any degree against the narrower portion of the isthmus, and we presume that even Mr. Bent would not attack the plateaus of Guatemala or Mexico.

K. J.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Spectroscopic Nomenclature

The letter of Captain Herschel upon "Spectroscopic Nomenclature," which appeared in Nature of April 25 contains many criticisms that are eminently just and timely, but there are one or two points in respect to which I should like to express dissent.

Thus as regards the name D_3 (to which he objects) for the yellow line of the chromosphere spectrum, it is not easy to see what other designation would better convey to the mind an idea of its position in the spectrum and its importance, without involving any assumption, or hypothesis even, as to the material causing it.

To say nothing of the fact that the whole Greek alphabet would not suffice to name one in three of the bright lines which have been observed in the chromosphere spectrum, there is this further difficulty, that if the letters are to be applied to lines in the order of discovery, ω is as likely to fall between α and β as anywhere else, but if according to position in the spectrum, then every discovery of new lines involves a revision of the nomenclature.

It seems doubtful therefore whether any better system is possible than to designate lines by reference to some standard map of the spectrum, as stars are catalogued by their right ascension and declination.

An accurate chart of the solar spectrum on which the lines should be mapped according to "inverse wave-length," proposed by Captain Herschel himself I believe, as well as by Mr. Stoney and others, would sufficiently resemble the spectrum seen in a spectroscope to be equally convenient in the observatory with that of Kirchhoff, and would be free from the reproach of arbitrariness and irregularity in its scale. Such a chart would be most gladly welcomed by all spectroscopists, and would immediately supersede those of Kirchhoff and Angström.

With reference to the green corona line, he writes "and now we have '1474.' No one knows what the true position of that line is. The line 1474 K is an iron line, and it is to the last degree improbable that the corona line is identical with it." I am not quite sure what is meant by the second clause. If only, that the position of this line may *possibly* (not by any means *probably*) be doubtful to the extent of $\frac{1}{4}$ of one of Kirchhoff's scale divisions, that is about $\frac{1}{4}$ the distance between the two E lines, I have nothing to object.

But if the sentence is intended, as one would naturally suppose, to convey the idea that the position of the line is not very accurately determined, and may be considered uncertain to the extent of several scale divisions, it is certainly wrong. I *know* of what I affirm, and perhaps may be allowed to refer to an article in this journal for Feb. 2, 1871, in which the evidence is stated as it was at that time, and it has received confirmation since.

Indeed as this bright line is almost always visible in the chromosphere to an instrument of sufficient power, I think I may confidently appeal to Mr. Lockyer or Dr. Huggins to bear me out in the statement that the bright scarlet line of the chromosphere appears to coincide no more perfectly with the dark C, than does this green corona line with the dark line at 1474 K.

I confess I am almost sorry that the spectrum of iron shows a bright line coincident with 1474, for all things considered, I cannot think that iron vapour has anything to do with this line in the spectrum of the corona, and the coincidence has probably only served to mislead.

But there are in the spectrum many cases of lines belonging to the spectra of different metals coinciding, if not absolutely, yet so closely that no existing spectroscope can separate them, and I am disposed to believe that this close coincidence is not accidental, but probably points to some physical relationship, some similarity of molecular constitution perhaps, between the metals concerned.

So in the case of the green coronal matter, is it not likely that, though not iron, it may turn out to bear some important relation to that metal? And yet I for one should be very glad if the application of higher dispersive power should show the apparent coincidence to be merely a very close juxtaposition.

Historical Note on the Method of Least Squares

This excellent method for the discussion of observations was published and first practically applied by Gauss in his Theoria Motûs, 1808. In the *American Journal of Science* for June 1871, Mr. Cleveland Abbe has shown that Prof. Robert Adrain, of New Brunswick, New Jersey, U.S., independently discovered the same method in 1808. I wish to call attention to what seems to me a singular oversight in the history of this subject, viz., to

the fact that in 1770—1773, Lagrange published an elaborate memoir at Turin under the title "Mémoire sur l'utilité de la Méthode de prendre le Milieu entre les resultats de plusieurs Observations," &c. *Vide* "Œuvres de Lagrange," edited by J. A. Serret, vol. 2.

I have never seen any notice of this memoir except a translation of a part of it into German by Encke, published in the *Berliner Jahrbuch* for 1853. Thus in the abstract of a memoir by Mr. J. W. L. Glaisher, given in the notices of the Royal Astronomical Society for April 1872, the name of Lagrange does not occur.

I think that the English mathematician, Thomas Simpson, busied himself with this problem about 1750, but I am not able to refer to his works. ASAPH HALL

The Volcanoes of Central France

AN unlucky error, perhaps mine, in the letter on the "Volcanoes of Central France," p. 80, will quite prevent any reader finding the paper I mentioned of May 1865, which, instead of being in the *Gentleman's Magazine*, was in the *Englishman's Magazine*, a short-lived periodical, begun and ended, I think, with that year. As your two correspondents, Prof. Corfield and the Rev. Mr. Webb, like the writer of that paper, repeat the late Dr. Daubeny's most marvellous "conclusion" that there might have been nothing more eruptive in the phenomena than "bursting out of flames" from earthquake fissures, and even that the fires mentioned by Sidonius and Avitus might be "domestic conflagrations," may I briefly indicate the grounds that make these suppositions to me incredible? These fires, as named in the portions of each document that I have translated—quite distinct from the conflagration of some public building on the Easter festival of a previous year, which both writers afterwards relate at greater length as an earlier and less known case of successful prayer by Mamertus, the memory of which had encouraged him under these "prodigies" and "portents," the *ignes* (not *incendia*) that both writers make a chief or the chief part of the "terrors"—(Sidonius, indeed, names the earthquakes before them, but Avitus twice over puts the fires first)—these were *crebri* and *assidui*, continual for two or three years, yet not a word of what they fed on or what valuables they destroyed, and they were only *sæpe flammati*. Their being so sometimes is plainly named by Sidonius as an unusual and greater portent. Now, I never heard of any "domestic" fires that were *not* "*flammati*," whereas volcanic eruptions, even severe, seldom if ever involve flame truly so called, though their strongly illuminated smoke may often by night be mistaken for flames, and has led them to be called in extreme cases, as Sidonius here said, *sæpe flammati*. He adds that when thus "*flammati*" they did, or rather threatened to do, the only mischief named as even apprehended from them at the capital, the endangering frail roofs by a load of ashes thrown over, *superjecto favillarum monte*. Now, surely this is not an effect of any ædile conflagrations however often repeated (a repetition that would anywhere have been regarded rather as suspicious of incendiarism than as "prodigious" and preternatural). Nor would any such accidents lead Avitus to ask in his sermon to those who remembered all, "Who would not dread the Sodomitic showers?" Again, Mr. Webb conceives that earthquakes might not only drive the wealthier part of the population out of the city, "but, as it would seem, the beasts into it!" I never heard of shocks producing so singular an effect as driving any living thing into cities or buildings, and cannot conceive what natural event could so drive them, unless what is here by both witnesses implied, "Sodomitic showers" of hot or cumbering *favillæ*. Such showers, which we know to be often carried, from eruptions involving no lava, scores or even hundreds of miles, in the direction of the prevailing winds, would be carried from any of the well-known cones of the Forèz or Vivarais, towards, or even far beyond, Vienne; and wild animals, fleeing north-eastward, would have no refuge but under roofs; and if private house doors were habitually shut (as now in England) might crowd into the colonnades (*fori latera*) of that capital city. This incursion of the wild deer, bears, and wolves into towns was so well remembered as to become, in the later chroniclers, Gregory of Tours, &c., dwelt upon among the main "prodigies" of the time, along with the earthquakes and burnings of buildings, though any other fires cease to be implied; and the reason of this is obvious on comparing their accounts. They all copy one another, and the earliest, whose sole authorities were those two pompous and involved writers, mis-read them exactly as our moderns (except Sir F. Palgrave) appear to have done, confusing together the fires of the "prodigies," that led to the Rogation fasts with the earlier ædile conflagration at some Easter, said to have been prayed out by Mamertus, which occupies both the writer and preacher immediately after, and at greater length than these well-known "terrors" remembered by those they addressed personally.

The whole strikingly shows, as Sir F. Palgrave said, the fallacy of geological inferences from the "silence of history" (or what may be deemed silence) in times and places practically prehistoric, or at least preter-historic. He showed that, but for Pliny and a mere accident, we should probably have been as ignorant of even the Pompeii and Herculaneum eruption as of these equally attested ones. Again, the Spaniards would have preserved us no memory of the rise of Jorullo, in the very last century; and yet probably no part of Gaul in the generation when the Romans lost it was really more settled and populous than Mexico in its third century of Spanish rule. The only important colonies within moderate shower-range of the eastern volcanoes were Vienne and Lyons, the latter farther off, and not at that time a capital, indeed but little heard of in those early middle ages. And fires, not called damaging, only "prodigious" and terrifying to Vienne, and causing "Sodomitic showers" there, need not have been within a few miles, but far in the wilds, then hardly trodden, of its mountainous south-western horizon.

Temperature of the Deep Sea

WILL you allow me to ask, through your pages, if there be any rule for ascertaining the temperature of the sea at given depths below the surface? To practical electricians such a rule would be very valuable.

I will state a case. There is a submarine cable connecting two stations, A and B, 150 miles distant. The temperature at A is 75° Fah.; that at B, 68° Fah.; and the average depth at which the cable lies 120 fathoms: what is the average temperature of the cable?

If you could refer me to any work in which this point is treated I shall be obliged. F.

ENDOWMENT OF PROFESSORSHIPS

THE following correspondence between Professors H. E. Roscoe and B. Stewart, of Owens College, Manchester, and the Chancellor of the Exchequer, is published in the *Times* of Monday last:—

"TO THE RIGHT HON. ROBERT LOWE, CHANCELLOR OF THE EXCHEQUER.

"Owens College, Manchester, May 21, 1862.

"SIR,—In the *Times* of May 17 you are reported, at the presentation for Degrees at the University of London, to have pointed out 'how the endowment of Professorships naturally tended to make teaching inefficient (seeing that the revenues come in independently of the results of teaching), suggesting that those who had any money to spare for the advancement of education should rather make it available in the forms of Scholarships and Exhibitions.'

"While we gratefully acknowledge the many services which, as Chancellor of the Exchequer, you have rendered to the cause of knowledge, we yet feel most strongly that the above expressions are calculated to mislead, and that were your suggestions to be carried out, the result would be fatal to the higher education of this country.

"We therefore request permission to lay before you our own views on this most important subject. Writing from the very house once inhabited by Cobden, we feel proud to be connected with a city which was the birth-place of Free Trade; yet we feel equally privileged to form part of a very useful institution which never could have existed

except in apparent contradiction to the principles of Free Trade.

"That the foundation by the late John Owens of Professorships of Arts and Sciences in the midst of this great city was not thought by Cobden to be subversive of his principles is proved by the fact that he himself was one of the original trustees, yet this conclusion does not appear equally clear to all of his disciples.

"We are, in sober truth, utterly at a loss to conceive how the higher education of the country can be efficiently carried on without a moderate endowment of its Professorships. The necessity for such an education you yourself admit.

"A single example from our own staff, which, more or less, applies to other places and subjects, will render our argument clear. It is evidently of very great importance that in a place like Manchester the citizens should be taught by a master mind the principles of political economy, and they have been fortunate in being able to avail themselves of the services of such a man as our colleague, Professor Jevons. But, although here both elements of pecuniary success might appear to be present in an intelligent public and a first-rate teacher, the fact remains that without the (misguided !) endowment of our founder the few who attend his lectures could not have benefited from the teaching of Professor Jevons unless the fees of attendance had been enormously increased. Indeed, we question whether the great apostle of Free Trade himself would have ultimately met with success had he not first of all received some sort of protection and support.

"We are naturally led by the instance we have quoted to remark that endowments really tend to diminish the expenses of education, and, looking around us, we see that in University College and King's College (London), where there are no endowments, they cannot afford to give their education at so low a figure as is possible at Owens College and in the Scotch Colleges, where endowments exist.

"In the German Universities, again, where all the important Chairs are well endowed, the expenses of education are almost nominal. In Scotland the education is in some branches of a very high standard, and in others great improvements have recently taken place, chiefly in the direction of relieving the head Professors from the duty of teaching junior classes which pay, and of enabling them to devote their energies to senior classes which do not pay. Such, in Scotland, have been the effects of endowments. Again, with regard to Germany, we have never heard any complaints made of the inefficiency of the German Professors.

"We must candidly own that we were much surprised by your statement as to the advisability of simply founding Scholarships and Exhibitions, coming, as it does, from a distinguished Oxford man well acquainted with the present state of feeling in the older Universities. Is it not true that this feeling is strongly against the extension of the already too numerous Scholarships, Fellowships, and other incitements to study, and in favour of the application of these funds to increase the paltry salaries of the Professors ?

"The excessive endowment of Scholarships appears to us to be objectionable, as an instance of unnecessary protection, where, by means of a hotbed regimen, young men are induced to enter a profession for which there is no subsequent career.

"While we admit that in a perfect state of society (unhappily still far distant) the laws of supply and demand may perhaps be applicable to all knowledge, yet we must point out that the teachers of the higher branches have too often now to create a taste for the commodity which they supply, and hence we believe that the moderate endowment of Professorships, such as exists in our own case, is essential to the progress of civilisation in this country.

"In conclusion, Sir, we cannot understand why endowment naturally tends to make teaching inefficient in the case of a Professor of science or arts more than it does in that of a minister of religion or a statesman.

"Are they not all servants of the nation administering to its higher needs ? The teacher of science or of the arts will, we venture to say, be no less conscientious and faithful to the true interests of a noble cause in teaching his class than the minister of religion in addressing his congregation, or the Minister of State in addressing his constituents.

"We are, Sir, your obedient servants,
"HENRY E. ROSCOE, B.A. (Lond.) F.R.S.
"BALFOUR STEWART, LL.D., F.R.S."

"11, Downing Street, Whitehall, May 23, 1872

"Gentlemen,—The speech which I made at the annual meeting of the London University occupied three-quarters of an hour, and was reported in a few lines. I never alluded to Professors, but spoke only of teachers, meaning those who do the drudgery or hard work of teaching, not those who are devoted to the investigation and inculcation of higher and more refined knowledge. I have the greatest respect for Mr. Jevons, and do not doubt that the endowment of his Chair is money well laid out.

"I also agree—indeed, I said—that the endowment both of Fellowships and Scholarships at Oxford and Cambridge is excessive ; but I pointed out how hard the competition was for the London University, with strict examinations and hardly any endowment, against Oxford and Cambridge, with rich endowments and easy examinations. I added that in my judgment money was better spent in giving Exhibitions to young men, leaving them free to choose the place of their education, than in paying persons to teach them ; since in the one case the inducement to the teacher to work was diminished, while in the other the student with money in his hand was sure to find the best teacher for himself.

"I am, Gentlemen, your obedient servant,
"ROBERT LOWE.

"I am an older Freetrader than Mr. Cobden, and am by no means prepared to assent to his views in all respects."

---

*GLAISHER'S (HALL'S IMPROVED) RAIN GAUGE**

IN the first paragraph of my "Notes on the Rainfall of 1871," which recently appeared in NATURE (vol. v., p. 481) your readers will probably have noticed certain reference to the above.

The improvement to which I refer consists of an *inverted rim* (similar to the rim or flange in which the receiver stands) fixed to the outside cylinder of the receiver, and made sufficiently large to admit of its dropping over the rim or flange, sometimes called "channel," fixed to the lower cylinder, *id est*, the one just mentioned in parenthesis.

The *inverted rim* is shown by a thick line on the right of the accompanying half-sectional diagram.

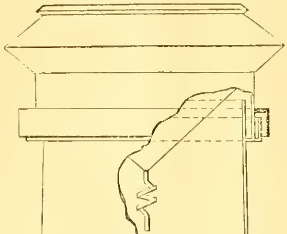
The reason that I suggested this addition was, that on one occasion, while registering the daily rainfall at Twickenham, during the winter of 1869-70, I was unable to take the receiver off, owing to the already existing channel being partly filled with water, which had frozen hard during the night.†

It is intended that water should be collected in the flange (Glaisher's) I have spoken of, and thus close the gauge against evaporation, scarcely a good idea theoretically, *certainly not practically*, inasmuch as the water

* Vide *Scientific Opinion*, vol. iii. pp. 449, 450.

† In order to avoid the interference of houses and trees, my gauge was supported at this time on a bracket carriage, running in vertical slides from a staircase window to a point a few feet above the roof of my residence.

collected therein so soon evaporates, especially in hot weather; *vide* "Symon's British Rainfall, 1868;" "Rain Gauge Experiments at Strathfield Turgiss, Reading," by the Rev. C. H. Griffith, F.M.S., &c., p. 23, which further establishes my remarks. The absence of outlet for confined air here spoken of, might be remedied, if indeed needed, by drilling small air-holes in the bottom of the receiving cylinder and upright flange, *but not facing each other*. I have two Glaisher's gauges fitted with the inverted flange arrangement, both of which answer remarkably well. I believe the improvement which I have adopted is more effectual against loss by evaporation (during all weathers) than the present (Glaisher's) system.



One of my gauges has been further improved at my suggestion by being fitted with a spiral or *helical* pipe in the place of the J-shaped pipe, thereby presenting no direct opening for evaporation, at the same time offering little or no hindrance to the speedy descent of the rain-water; but this is a matter I hope to enlarge upon in a paper (as yet unpublished) which I hope to communicate to you shortly, "On a Proposed New Form of Rain Gauge (the Atmospileometer)," in which a similar, but more extensive, idea, is shown.

The particulars mentioned in paragraphs 1 and 3 of this letter were long since communicated to and approved by the Secretary of the Rainfall Committee of the British Association (G. J. Symons, Esq., F.M.S., &c.) one of the highest authorities in matters relating to rainfall.

JOHN JAMES HALL

WATER ANALYSIS

I.

IT is now upwards of twenty years since the inhabitants of this country, and especially of the metropolis, were awakened, by a succession of virulent attacks of epidemic cholera, from the profound indifference with which they had regarded all matters connected with the public health for the hundred and eighty years which had succeeded the Great Plague. During that interval builders had been allowed to cover land with hundreds of acres of dwellings built without regard to ventilation, drainage, or water supply. In all the towns and villages of the country the ground was honeycombed with cesspools and wells, the latter deriving their supply of water at least in part from the former, and in all riverside towns the river either received the town sewage at once or after it had passed through the cesspools. Attention once being drawn to the matter, it became the duty of the chemist to detect the various polluting matters introduced by the sewage into the different sources of water-supply, and to discover, if he could, waters that were free from this pollution; and a still greater field was opened up, for the two first inquiries naturally led to the allied questions—How can sewage be rendered harmless? and Can slightly polluted water be rendered safely drinkable by the removal from it of the contaminating matter introduced by sewage? We propose in this article to look only at the first of these questions, the one on the successful solution of which depend all the others—Can organic contamination be detected and estimated with accuracy? As soon as the question was approached it was found to be one of extraordinary difficulty, and in 1856 Hofmann and Blyth drew attention to the inaccuracy of the then existing processes, especially of the one known as "loss on ignition" obtained by igniting the solid residue on the evaporation of the water. This loss, then generally looked on as affording a measure of the organic matter present in the water, they proved to consist of a loss of carbonic anhydride, nitric acid, ammonia, and moisture, &c., and they proposed to render the determination more accurate by the addition of a known weight of sodic carbonate, which, while it drove off the ammonia (usually a very small fraction of the loss), retained the acids and prevented the aqueous magnesic chloride from losing hydrochloric acid. The same chemists pointed out the necessity of determining the amount of nitrogen present, but were unable to recommend any process for its estimation. The methods for estimating the ammonia were also very unsatisfactory, for we find Dr. Dundas Thomson in 1855 distilling as much as fifty gallons of the metropolitan water-supplies in order to estimate the ammonia, which was done by titration with standard acid; and this when some of the metropolitan supply was taken from the Thames at Vauxhall, and "Fibrin from Fæces" could be distinctly recognised in the Southwark Company's water. Another process, devised by Forchhammer, was also in use for the determination of the organic matter, which consisted in adding a standard solution of potassic permanganate until no further loss of colour occurred. This process had been improved from time to time, and was and is largely used. The only other test was that for hardness, invented by Dr. Clark, and which is still in use, with but slight modification from the original method.

If these processes are considered but shortly, the defects they possess are at once apparent. Take, for instance, Hofmann and Blyth's improved solid residue process. On ignition there was great danger of decrepitation and consequent loss, notwithstanding the high temperature (120° to 130° C.) to which the residue had been exposed. Frankland and Armstrong have shown that portions of the nitrogenous matter were liable to remain fixed in the ignited residue as cyanogen compounds. Again, in the case of some artificial residues prepared by treating dilute solutions of urea as in the above process, from 44 to 59 per cent. of the urea used was found to have been lost during the preliminary evaporation, the sodic carbonate having expelled it as ammonic carbonate. And on the treatment of similar residues by ignition, from 58 to 85 per cent. of the organic matter was left in the residue. It was usual also to restore the lost carbonic anhydride to the ignited residue by evaporating a solution of that gas on it and weighing until a fresh treatment did not increase the weight; but to still further increase the difficulty of this unhappy process, it was shown that some residues seemed to have the power of taking up such quantities of carbonic anhydride, that they weighed more after this treatment than they did before ignition. The estimation of ammonia by titration with acid needs no argument against it; the enormous quantities of water necessary for the determination sufficiently condemn it; and it has been long superseded by the admirable quantitative form of the Nessler process invented by the late Mr. Hadow, of King's College. The permanganate process, however, being an easy one to perform, still survives in the laboratories of many analysts. Indeed, not content with giving the results of this determination as "oxygen required to oxidise the organic matter present," the lively imagination of some led them to the remarkable conclu-

sion that every grain of oxygen oxidised eight grains of "organic matter."

Whether this test is to be trusted may be judged from the following facts. Potassic permanganate is deoxidised by ferrous salts, nitrites, sulphites, &c., much more rapidly than by organic substances, so that a water absolutely free from any organic matter, but containing one of these compounds, would be set down as requiring so much "oxygen to oxidise organic matter." Secondly, in the case of water to which known weights of various organic compounds were added, Frankland and Armstrong found that in no instance was the oxidation complete, even after the lapse of six hours. In fact, even after that time the amount of oxygen actually absorbed was in every case a mere fraction of the quantity actually required to completely oxidise the organic substance. The test, though thus shown to be valueless as quantitative, is of some value qualitatively, as it can be easily and quickly applied; and it may be said that, though it might induce a person to abandon a good water, it would not often lead him to use a bad one.

All the above processes were in use up to 1868, when Messrs. Chapman, Wanklyn, and Smith proposed to determine the organic matter in water from the amount of ammonia evolved when the water was treated with a strongly alkaline solution of potassic permanganate and then distilled, the ammonia being determined in the distillate by Hadow's modification of the Nessler test.

That albumin is decomposed and the nitrogen thus evolved, they had shown in a paper presented to the Chemical Society in the preceding year. The way in which this process was applied to the water may be briefly stated as follows:—A measured quantity of the water was rendered alkaline with freshly-ignited sodic carbonate, and the ammonia distilled off and estimated by Hadow's modified Nessler process. As soon as all the ammonia thus obtainable had been expelled, the alkaline permanganate solution (50 cubic centimetres of a solution containing 200 grammes of potassic hydrate and 8 grammes potassic permanganate per litre) was run in. The distillation was then resumed, and the ammonia estimated as before. This last was set down as "albuminoid ammonia," and as the average evolution of ammonia from the following substances, gelatine, caseine, dry albumin, uric acid, creatine, theine, dried fish flesh, amounted to 10 per cent., it was suggested the albuminoid ammonia multiplied by 10 gave a fair estimation of amount of organic matter.

It had at first been stated that albumin gave up the whole of its nitrogen when treated with alkaline permanganate, but the statement was subsequently modified to "It appears to be two-thirds, being at any rate a constant quantity." Now this process would indeed be a valuable one if the 10 per cent. average could be depended on, or if the albumin evolved a certain quantity, and the above substances were alone found in water. Unfortunately, none of these suppositions are true. With regard to the last, the authors themselves recognised the difficulty, and accordingly examined a number of other nitrogenous organic bodies; which examination led to the publication of two lists of bodies that evolve the whole of their nitrogen as ammonia, and bodies that yield various fractions. Frankland and Armstrong also made some experiments on this subject. With regard to the list of bodies yielding half their ammonia, the numbers given by the authors vary from 44 per cent. in the case of papaverine to 58 per cent. in the case of sulphate of cinchonine; and whilst narcotine appears in Wanklyn, Chapman, and Smith's list as evolving all its nitrogen, Frankland and Armstrong give it as evolving about 46 per cent. Strychnine, given by the former authors in their list as evolving 53 per cent., is given by the latter as evolving $31\frac{1}{2}$ per cent., and sulphate of quinine also in the list with 50 per cent., appears again with Frankland to have evolved nearly 57 per cent. No other examples will be necessary to show the extreme uncertainty of the process. If the authors had enabled us to ascertain the absolute error on the quantity taken instead of the per-centage error, by giving us the quantities from which the results were taken, it would no doubt be much more apparent; the results given above in the case of those from Frankland and Armstrong's paper are absolute errors.

But it may be urged in defence of the method that none of these bodies are found, or are likely to be found, in natural waters. Let this be granted, and the process must be defended on the albumin and other bodies mentioned, and on the list of bodies giving up all their ammonia. The average from this is 11·82 per cent.; from the albumin list, 9·92; or, taking the two, 10·87. So far the lists hold good. But it must be borne in mind that we have three different statements about the ammonia evolved from albumin—first, that all is evolved; secondly, "two thirds, or, at any rate, a constant quantity;" thirdly,* that 100 parts of albumin give 10 parts of ammonia.† The inconsistency of these statements needs but this comment, that they can only be caused by the extreme uncertainty of the process; in fact, the amount of nitrogen converted into ammonia will be influenced by the nature of its previous combination, the degree of concentration of the solution, and the amount of heat applied to the retort, and consequent rate of distillation and time to which the solution is exposed to the action of the alkaline permanganate. That this is the case is proved by the fact that water which has been distilled from alkaline permanganate, and gives no trace of reaction with Nessler's test, will evolve ammonia if again boiled with the permanganate. Lastly, let any one take a water which has been largely contaminated with sewage and then filtered, such as the effluent water from a sewage farm. Such water, as a rule, contains much nitric and nitrous acid, and comparatively small quantities of organic nitrogen. A water of this character continues to evolve albuminoid ammonia till boiled nearly to dryness, and not unfrequently the retort requires to be filled up with pure water, and the operation carried on. The process is thus not only rendered tedious, but the necessity of repeatedly taking samples of the distillate and estimating the ammonia in them introduces an amount of experimental error which becomes serious when calculated out in milligrams per litre, though its actual amount on each cylinder of distillate may be very small.

When it is added that Mr. E. T. Chapman has included in the second edition of Wanklyn's "Water Analysis" a process for the estimation of volatile organic matter, founded on the fact that water largely contaminated with sewage evolves volatile bases when boiled with potassic hydrate, the question is still further complicated; for it cannot be doubted that some portion of these bases would be driven off by the action of the alkaline permanganate before it had time to act on and destroy them.‡ Whether this is the case ought at once to be determined by those who use the process.

In a second article we shall consider Frankland and Armstrong's process for the analysis of potable water, and also those determinations, such as nitrous and nitric acids and chlorine, which are of great value as enabling us to trace back the history of a water, and to tell from whence it is derived and what it has received in the way of animal contamination before it came into our hands.

* "Water Analysis," 2nd edition, p. 66.

† If Lieberkühn's formula for albumin $H\,Na\,C_{72}\,H_{110}\,N_{18}\,S\,O_{22}, H_2O$ be taken as the true one, 10 parts of ammonia (NH_3) from 100 parts of albumin will be equal to 8·23 parts, or little more than half the total nitrogen, which is for that formula 15·25 per cent. If the sodium in the above formula be replaced by hydrogen, the discrepancy is still greater.

‡ An action of this nature apparently occurs when sewage is treated with alkaline permanganate, as nearly the whole of the ammonia comes off in the first 100 cub. cent. of the distillate, and after that the evolution soon stops, Waters that evolve small quantities of albuminoid ammonia seem almos always to require a long time for its liberation. Is this because the organic bases are so diluted that they cannot be driven out, and so slowly decompose

RADIATION AT DIFFERENT TEMPERATURES

BALFOUR STEWART states in his "Elementary Treatise on Heat" that "Newton was the first to enunciate his views on the cooling of bodies. He supposed that a heated body exposed to a certain cooling cause would lose at each instant a quantity of heat proportionate to the excess of its temperature above that of the surrounding air." In order to prove the fallacy of Newton's supposition, Prof. Stewart presents the following extract from the work of MM. Dulong and Petit:—

Excess of temperature of the thermometer.	Velocity of cooling.
°C	°C
240	10·69
220	8·81
200	7·40
180	6·10
160	4·89
140	3·88
120	3·02
100	2·30
80	1·74

"We see at once from this table," says Prof. Stewart, "that the law of Newton does not hold, for according to it the velocity of cooling for an excess of 200° should be precisely double of that for an excess of 100°; now we find that it is more than three times as much." The author of the Elementary Treatise on Heat thus assumes that the velocity of cooling established by Dulong and Petit represents the radiant energy or quantity of heat transmitted by the radiator. Consequently, the amount of energy at 200° is assumed to be $\frac{10 \cdot 69}{1 \cdot 74} = 6 \cdot 14$ times greater than at 80°; while, agreeably to Newton's law, the increase of radiant energy should be proportional to the differential temperature, viz., $\frac{240}{80} = 3$ times that of the tabulated temperature of 80°. Modern research having established that radiant heat is energy amenable to the laws of dynamics, it may be demonstrated that the deviation from the Newtonian doctrine assumed by Dulong and Petit is groundless; but, before considering the theory, let us examine the practical result of recent elaborate experiments conducted with an apparatus containing the spherical radiator adverted to in the preceding article on Solar Temperature (vol. v. pp. 505-507). The accompanying illustration (Fig. 1) represents a vertical section of the said apparatus, *a* being a spherical vessel 5 inches in diameter, suspended within an exterior casing *b*, filled with water. A spherical radiator, *c*, 2·75 inches in diameter, composed of very thin copper, charged with water and coated with lamp-black, is sustained in the centre of the sphere *a* by means of tubes applied above and below. The upper tube is large enough to admit the bulb of a thermometer, the lower one being only sufficiently large to accommodate a small axle, to which is attached a paddle-wheel, provided with curved paddles, arranged in such a manner that the bulb of the thermometer may be inserted considerably beyond the centre of the sphere, as shown in the illustration. The external casing *b* is provided with nozzles, *g* and *d*, to which tubes are attached for circulating cold water through the annular space during experiments. The air is exhausted from the spherical enclosure through the tube *k*, which passes across the annular space. It will be evident that the centrifugal action of the paddles of the wheel applied within the radiating sphere will produce a continuous current from the centre towards the circumference, the fluid successively passing over and coming in contact with the inside of the thin shell, then returning to the centre to be again thrown off by the centrifugal action. The rotary motion of the water, kept up without intermission round the cylindrical bulb of the thermometer, will evidently render its indication prompt and reliable. It is hardly necessary to observe that the rapid presentation of fresh particles of water promoted by the action of the paddles, will effectually prevent the reduction of temperature to proceed faster at the circumference than at the centre, the radiation at the surface, in virtue of the continuous interchange of particles, affecting almost simultaneously every molecule within the sphere. Consequently the total energy of radiation will be rendered available in reducing the temperature of the contents of the radiator, while the central thermometer will indicate at every instant the precise degree of temperature of the entire mass.*

The mode of conducting the experiment will be seen by the following statement:—A wooden cistern containing 16 gallons, charged with water and crushed ice, is connected by flexible tubes to the nozzles *g* and *d* on opposite sides of the annular space, a pump being applied between the cistern and the said nozzles, by means of which the cold water is forced through the apparatus and then returned to the cistern.

In view of the great importance of the question at issue, the investigation has been conducted with the utmost care, four operators having invariably been employed during the experiments, the labour being thus divided: 1st operator regulates the temperature of the water in the cistern by continual agitation and supply of crushed ice from time to time; 2nd operator works the pump at a uniform rate; 3rd operator turns the paddle-wheel, and reads the thermometer under a magnifying glass, calling time for each degree at the instant when the top of the mercurial column is covered by half the thickness of the line on the scale. Lastly, the 4th operator, provided with a Casella chronograph, records the time called. It will be seen presently that, notwithstanding this procedure, there is a slight discrepancy in the ratio of temperature and time, viz., the increment of time for each degree is not regular. Obviously the most practised eye cannot determine exactly at what moment the top of the falling column is half covered by the line on the thermometric scale. Again a perfectly graduated thermometer cannot be obtained. But the discrepancy referred to in reality only disfigures the record, since the computations are based on *mean* time. Referring to the accompanying table, it will be seen that the rate at which the spherical radiator cools has been recorded separately for each degree of differential temperature from 100° to 10°, the enclosure being maintained at a constant temperature of 33°. Regarding the construction of the table, it will suffice to state that the time entered in the fourth column is that shown by the chronograph. It will be evident on reflection that the increment of time for each successive degree of differential temperature expresses very nearly the rate of cooling; but, the recorded times being irregular, from causes already pointed out, the true increment cannot be determined without ascertaining the mean time recorded by the chronograph. This mean time will be found in the fifth column, the true increment, viz., the number of seconds during which the temperature of the radiator falls one degree, being entered in the last column.

Let us now examine the accompanying diagram Fig. 2, in which the ordinates of the curve *a b* represent the observed time for each degree of differential temperature, while the ordinates of the curve *a c* represent the corrected time. The diagram having been constructed with the utmost exactness, in accordance with the temperature and time in the table, mere inspection will show that the observed and corrected times have produced curves nearly identical. Agreeably to Newton's law the rate of cooling is proportional to the excess of temperature of a body above that of the surrounding medium. Hence the increment of time for each degree, in other words, the number of seconds occupied in reducing the temperature of the radiator 1° (inserted in the last column of the table) should be proportional to the differential temperature inserted in the third column. For instance the rate of cooling at a differential temperature of 490° being 39·80 seconds for 1°, it should be $\frac{49 \times 39 \cdot 80}{31} = 62 \cdot 90$ seconds for an equal thermometric interval at a differential temperature of 31°. Referring to the table, it will be found that the rate thus computed agrees exactly with the increment of time inserted in the last column opposite the differential temperature 31°.

Applying a similar test to the other differential temperatures and rates of cooling contained in the table, the same exact agreement will be found to exist. Consequently, our table and diagram prove that the rate of cooling is proportional to the differential temperature, thus establishing the correctness of the Newtonian law. Regarding the discrepancy indicated by the slight irregularity of the curve *ab*, the writer attributes the same to the

* It might be supposed that the motion of the water within the radiating sphere, produced by the action of the paddle wheel, will occasion an elevation of temperature tending to render the indication of the central thermometer inaccurate. The requisite speed of the wheel being 30 turns per minute, experiments have been made to ascertain if at that rate heat is produced; but no elevation of temperature has been observed. The diameter of the wheel being 2·37in., the maximum speed of the particles of water produced by the rotation is scarcely 3·8ins. per second, a velocity too small to generate appreciable heat.

difference of emissive power of the radiator at different temperatures. It was stated in the preceding article, (vol. v. pp. 505-507), that the radiant power of one square foot of cast-iron develops 0·080 thermal unit per minute for each degree of differential temperature at 65°, and 0·337 unit at 3,000°; hence that the emissive power is increased $\frac{0·337}{0·080}$ = 4·21 times for an increment of 3,000 − 65 = 2,935°. Experiments conducted in the

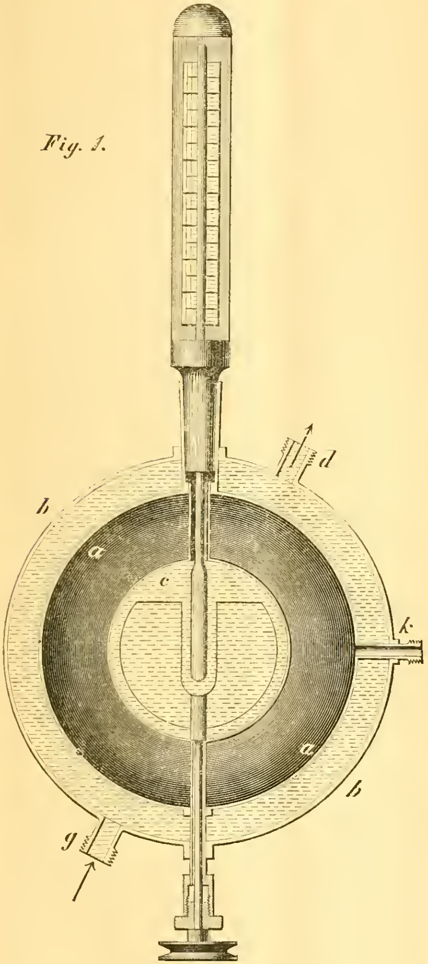


Fig. 1.

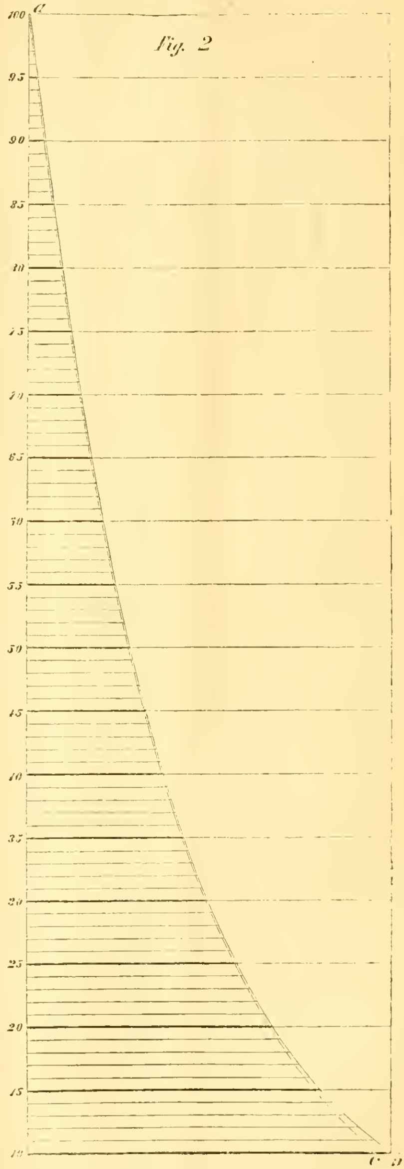
mean time show that the radiant power of one square foot of cast iron maintained at a differential temperature of 1,800° is 335 units per minute, hence that the emissive power at this stage of incandescence amounts to $\frac{335}{1,800}$ = 0·186 unit for each degree of differential temperature. Our investigations have thus proved that at 65° the emissive power is 0·080 thermal unit, at 1,800° 0·186 unit, and at 3,000° 0·337 for each degree of differential temperature. We have accordingly established the fact that the

Fig. 2



emissive power increases nearly in the same ratio as the intensities, being fully quadrupled between the differential tempera-

ture of 65° and 3,000°. Let us be careful not to confound this increase of emissive power with the increase of radiant energy resulting from mere augmentation of temperature. It is, no doubt, owing to the change of the molecular constitution of the body during heating that the dynamic energy developed at a differential temperature of 3,000° is 4·21 times greater than it should be in accordance with the Newtonian law—a trifling increase, however, compared with that resulting from adopting the computations of Dulong and Petit, whose formula shows that for the stated range of temperature the ratio of radiant energy will be increased more than 4,000 times. It would be premature to attempt to explain the cause of the change of the radiant properties of metals at different temperatures disclosed by our experiments, until further investigations shall have established the exact relation between the actual and theoretical energy developed. Considering the difference of molecular motion within metallic bodies at white heat in a state of fusion, and at the freezing point of water, we need not be surprised at the variation of emissive power observed during our experimental investigation. Nor are we justified, in view of this variation of emissive power, in questioning the correctness of Sir Isaac Newton's assumption that heated bodies of definite radiant properties develop mechanical energies proportional to their excess of temperature over the surrounding media.

Temperature of the radiating sphere.	Temperature of enclosure.	Differential Temperature.	Observed Time.	Corrected Time.	Increment of time for each degree.

J. Ericsson

[We have received a communication by cable from the author, to the effect that the engraver has indicated, in Fig. 2, a continuous space between the curves *a b* and *a c*, whereas the space should cease at one portion, the curves intersecting each other between the ordinates 25 and 30. The mistake is so trifling that it can scarcely be observed with the naked eye, yet it will no doubt be detected by such men as Stewart, Maxwell, and Everett. It is to be found, on looking at the table, that the observed times are shorter than the calculated times at the high temperatures, while the observed times are longer than the calculated times at low temperatures; hence the curves must intersect each other.—Ed.]

NOTES

The *Pall Mall Gazette* states that the Earl of Portsmouth, who is the collateral representative of Sir Isaac Newton, has offered to the University of Cambridge, through the Duke of Devonshire (Chancellor of the University), all the papers of Sir

Isaac relating to scientific subjects which his lordship has inherited. Lord Portsmouth's gift is prompted by the feeling that these papers will be more fitly deposited in the library of the University of which Sir Isaac was so distinguished an ornament than in his own muniment-room.

THE visitation of the Royal Observatory took place on Saturday last. We have not yet received the Astronomer Royal's report; but there is a rumour that it will be proposed to the Government by the Board of Visitors that photographic and spectroscopic observations of the sun be added to the routine work of the Observatory.

IT has been decided that the first Meeting of the French Association for the Advancement of Science shall be held at Bordeaux in the autumn of the present year.

THE Prince of Wales will open the Bethnal Green Museum on Monday, the 24th inst. The Princess of Wales will accompany him. We should be glad to hear of free Scientific Lectures in connection with this Museum.

WE are glad to learn that the Royal Geographical Society are taking steps to press upon Government the importance of an expedition to the North Pole by way of Smith's Sound.

IN another column will be found a correspondence between the Chancellor of the Exchequer and Profs. Roscoe and Balfour Stewart with reference to the remarks made by the former at the presentation to degrees at the University of London, to which we drew attention a fortnight ago. It is with great satisfaction that we note Mr. Lowe's own version of his speech, on which we may say a word, although the accuracy of Mr. Lowe's defence has been called in question by Prof. Sylvester. If he and the Government which he represents remain firm to their avowed declaration in favour of the endowment of the higher professorships, the cause of scientific education will have reason to be grateful, the Professor being distinguished from the teacher by the presence of *investigation*, as well as of inculcation. The *Pall Mall Gazette* called attention in a forcible manner last week to the fallacies of the line of argument which Mr. Lowe was represented to have employed. To encourage a plethora of scholarships at the expense of the endowment of professorships would be a more perfect illustration of the maxim "How not to do it," than we have witnessed this long time.

THE proposed alterations in the examinations held during the first two years of a student's course in the University of Cambridge were submitted on May 30 to the Senate with varying success. The vote was taken on the principle, and not on the details, of the various propositions. The most important of those accepted were—to receive a knowledge of French and German as a substitute for Greek in the first or "Previous" Examination; and to add Heat as a subject in the "General" or Second Examination for the Ordinary Degree. The effect of these changes, when finally ratified, will be that a degree in Honours, in either Mathematics, Law, Natural or Moral Science may be obtained by a student who does not know Greek; but that an ordinary "Poll" or Pass Degree cannot be obtained without a knowledge of Greek. Also, a candidate for a degree in Honours will not be required to study (necessarily) any branch of Physical Science; but a candidate for a "Poll" Degree must have an elementary knowledge of Heat. As, however, several persons, in the debate which preceded the voting upon these questions, expressed themselves favourable to making some branch of Natural or Physical Science a part of the Previous Examination, it is, we conceive, not improbable that the Syndicate will embody some proposition of this kind in their amended scheme.

THE following arrangements are now made for the forty-second meeting of the British Association for the Advancement of Science, to be held at Brighton, and to commence Wednesday, August 14, under the direction of the following officers:—President—Dr. William B. Carpenter, F.R.S. Vice-Presidents—The Earl of Chichester, the Duke of Norfolk, the Duke of Richmond, K.G., the Duke of Devonshire, K.G., F.R.S., Sir John Lubbock, Bart., M.P., F.R.S., Dr. Sharpey, LL.D., Sec. R.S., Mr. Joseph Prestwich, F.R.S. General Secretaries—Dr. Thomas Thomson, F.R.S., Capt. Douglas Galton, C.B., F.R.S. Assistant General Secretary—Mr. George Griffith. Local Secretaries for the Meeting at Brighton—Mr. Charles Carpenter, Rev. Dr. Griffith, Mr. Henry Willett, the Pavilion, Brighton. Local Treasurer for the Meeting at Brighton—Mr. William H. Hallett, F.L.S. General Treasurer—Mr. William Spottiswoode, F.R.S. The General Committee will meet on Wednesday, August 14, at 1 P.M., for the election of Sectional Officers, and the despatch of business usually brought before that body. On this occasion there will be presented the Report of the Council, embodying their proceedings during the past year. The General Committee will meet again on Monday, August 19, at 3 P.M., for the purpose of appointing Officers for 1873, and of deciding on the place of meeting in 1874. The concluding meeting of this Committee will be held on Wednesday, August 21, at 1 P.M., when the Report of the Committee of Recommendations will be received. The first general meeting will be held on Wednesday, August 14, at 8 P.M., when the President will deliver an address; the concluding meeting on Wednesday, August 21, at 2·30 P.M., when the Association will be adjourned to its next place of meeting. The different Sections will assemble in the rooms appointed for them, for the reading and discussion of Reports and other communications, on Thursday, August 15, Friday, August 16, Saturday, August 17, Monday, August 19, and Tuesday, August 20, at 11 A.M. precisely. Authors are reminded that, under an arrangement dated from 1871, the acceptance of Memoirs, and the days on which they are to be read, are now, as far as possible, determined by Organising Committees for the several Sections before the beginning of the meeting.

PROFESSOR RUTHERFORD, of King's College, London, has been appointed Fullerian Professor of Physiology to the Royal Institution, in the place of Dr. M. Foster.

THE *British Medical Journal* gives currency to a report that a baronetcy is about to be conferred on Dr. William Stokes, Regius Professor of Physic in Trinity College, Dublin, and Physician to the Queen in Ireland.

WE have to record the death of one of our veteran botanists, Dr. Robert Wight, F.R.S., who died May 26, at his residence, Grazeley Lodge, near Reading, at the age of 76. Dr. Wight was a native of East Lothian, and very early in life entered the medical service of the East India Company, and while in this employment devoted his energies to the investigation of the then almost unknown flora of the British possessions in India. In 1834 he published, in conjunction with the late Prof. Arnott, the first volume of the "Prodromus Floræ Indiæ Orientalis," a work which was never continued. Further contributions to Indian botany were contained in his "Illustrations of Indian Botany," "Icones Plantarum Indiæ Orientalis," and "Spicilegium Neilgherrense," and in innumerable contributions to magazines and to the proceedings of societies. His name will also always be associated with his exertions towards the introduction of the cultivation of cotton into India. Dr. Wight was one of a band of botanists, to which Sir W. Hooker, Lindley, and Arnott belonged, who have now almost entirely passed away.

MR. JOHN B. LAWES, of Rothamsted, Herts, has announced his intention of placing in trust his laboratory and experimental

fields with the sum of 100,000*l.*, the interest of which, after his death, is to be applied to the continuation of the investigations which have been carried on for so many years at Rothamsted. It is seldom that we have to record an act of so great munificence directed in a channel calculated to bring about such important results to the scientific department of agriculture.

PROF. WATSON, the indefatigable planet hunter of the Ann Arbor Observatory, reports the discovery, on May 12, 1872, of a new asteroid (No. 121) of the eleventh magnitude. The following observations are communicated by him to *Harper's Weekly* :—

Ann Arbor.	Mean Time.	Right Ascension.	Declination.
May 12	$14^h\ 13^m\ 42^s$	$16^h\ 20^m\ 37{\cdot}58^s$	$-18°\ 53'\ 9{\cdot}4''$
,, 13	$11^h\ 13^m\ 22^s$	$16^h\ 19^m\ 59{\cdot}35^s$	$-18°\ 52'\ 46{\cdot}2''$

Daily motion in right ascension, -43^s; in declination, $+26''$.

PROF. FLOWER's lectures on the Comparative Anatomy of the Organs of Digestion of the Mammalia lately delivered at the Royal College of Surgeons of England are being published with illustrations in the *Medical Times and Gazette*.

THE last Swiney lecture of the present year will be delivered on Saturday next, when the general subject of Science in relation to Education will be considered. This will terminate Dr. Cobbold's tenure of the Chair, which is only open to medical graduates of the Edinburgh University. The collective attendances for this series of sixty discourses will, we understand, have registered a total of upwards of 15,000, a result which is gratifying to the friends of popular scientific instruction.

MR. CARRUTHERS has printed his Official Report for 1871 of the Department of Botany in the British Museum. In consequence of the extent of the recent additions to the general herbarium, additional cabinets have had to be incorporated, and the old ones rearranged. The exhibition rooms have also been rearranged, with a view of making them more instructive and attractive to visitors. Several natural orders in the General and British Herbaria have been rearranged. Among the more important additions to the General Herbarium are 17,000 species, chiefly from Central Europe, Alsace, the Jura, the Lower Rhine, Spain, Mexico, and Labrador, being the herbarium of Auerswald, of Leipzig; 1,000 from Yucatan, collected by Dr. A. Schott; upwards of 1,000 from Russia; and upwards of 1,500 from Scandinavia, collected by Ahlberg.

IN a letter from General Otto Struve, director of the Palkowa Observatory, and Astronomer Royal of Russia, to Prof. Newcomb, of the Washington Observatory, detailing the Russian preparations for observing the forthcoming transit of Venus, and printed in *Harper's Weekly*, he remarks that the inquiries into the meteorological conditions of the stations selected have given, on the whole, very satisfactory results, particularly for the station on the coast of the Pacific Ocean and in Eastern Siberia (85 per cent. of clear sky for December). In two only of the stations chosen, Taschkent and Astrabad, these conditions are not sufficiently satisfactory. For this reason the observers designed for Taschkent will probably go to a place about 100 miles west of that town; and instead of Astrabad it is proposed to take either the island of Aschuradeh, in the Caspian Sea, or, if possible, to cross the Elburz Mountains, and establish observers at Schahrech, in Persia (with nearly absolute certainty of clear sky). The total number of Russian stations will be twenty-four, each of them provided with only one instrument for the transit observation. These instruments are—three 4-inch heliometers, three photo-heliographs, four 6-inch equatorials, and four 4-inch equatorials, provided with filar micrometers and spectroscopic apparatus, and ten 4-inch telescopes, designed merely for contact observations. Each station will also be furnished with clocks, chronometers, and the instruments necessary for exact determination of time. The principal instruments have already been ordered. Most of them will be ready for use in the course of the present or beginning of next year. For these instruments the observers are also in a great part already selected. They will all visit Palkowa for a certain time in 1873 to exercise themselves in the observations. The geographical positions of the stations will not be determined by the transit observers; but all stations on which the transit has been successfully observed will be carefully determined afterwards by special expeditions of the general staff or the navy. For this purpose a principal line of telegraphic longitudes will probably be laid next year through all Siberia to Nicolajevsk, with which line the other stations of that part of Russia can easily be joined, either by telegraphic or chronometric operations. With regard to photographic observations, Prof. Struve states that two observers, one at Vilna, and Dr. Vogel at Bothkamp, in Holstein, have been perfectly successful in taking instantaneous observations with dry plates.

THE Cambridge Natural Science Club has just issued its first terminal report. The club was founded March 11, 1872, by some of the undergraduates and B.A. members of the university for (Rule 1) "The promotion of natural science by means of friendly intercourse and mutual instruction." The number of members was at first limited to nine, but at the third meeting the number increased to twelve. The number is limited in order that the meetings may be held in the rooms of the members. Meetings are held every Saturday evening during term, and during eight weeks of the long vacation, in the rooms of the members in rotation. The member in whose rooms the meeting is held is president for the evening, and (Rule 7) "brings some subject of scientific interest under the consideration of the members in the form of a short paper, with such practical illustrations as the subject admits of." The papers read during this term have been the following:—By Mr. J. C. Saunders, B.A. (Downing College), "On Conspicuous Movements in Plants;" Mr. C. T. Whitwell, B.A., B.Sc. (London), Trinity, "On Isothermals;" Mr. C. J. F. Yule (St. John's), "On the Anatomy of Pyrosoma;" Mr. H. M. Martin, M.B., B.Sc. (London) Christ's, "On the Modes of Reproduction of Animals and Plants;" Mr. A. Liversedge (Christ's) "On Supersaturated Saline Solutions;" Mr. J. E. H. Gordon (Caius), "On Submarine Telegraphy;" Mr. P. H. Carpenter (Trinity), "On the History of the Abbeville Jaw."

A BOTANICAL and geological excursion class has been commenced in connection with the St. Thomas's Church Schools Birmingham. President, Rev. T. D. Halstead, rector; secretary, Mr. Miller (brother of the late celebrated chemist); conductor, Mr. John Turner, F.M.S. The class consists of twenty-five members, most of whom have attended science classes during the winter, and recently competed in the examinations of the Science and Art Department. The class meets every Saturday afternoon.

WE learn from the *British Medical Journal* that a committee, consisting of Profs. Bamberger, Billroth, Brücke, Duchek, and Schroff, has been appointed to select candidates to be invited to fill the chair of Pathological Chemistry at the University of Vienna. The names of Hoppe-Seyler (lately appointed to the University of Strasburg), Kühne (of Heidelberg), and Liebreich (of Berlin), are mentioned in connection with the post. The establishment of a professorship of Hygiene in the University is under discussion; and there appears to be a general agreement among the professors in the University as to the necessity of having such a chair instituted with as little delay as possible.

A FAIRLY perfect human skeleton has been discovered by Dr. Revière in the caverns of Baoussé-Roussé, near Menton, on March 26, and a short paper on this interesting find was read to the Academy of Sciences at a recent sitting.

*MR. BENTHAM'S ANNIVERSARY ADDRESS TO THE LINNEAN SOCIETY**

AS a general summary of the current zoological literature the "Zoological Record" maintains its high value. The volume for 1870 has lately appeared under the new editorship of Mr. Newton, and the arrangements now made for its further prosecution are very hopeful; yet I must again urge upon all our Fellows, who, as amateur zoologists or patrons of the science, have joined our ranks, to give their further support to the "Zoological Record" Association in order to secure the continuance of this annual summary for the sake of the working members, to whom it is so essential. I would also call attention to the sketch of the ornithological works recently published or in progress contained in the last number of the *Ibis*, an example which it were to be wished were regularly followed in all periodicals specially devoted to any branch of our sciences. The Reports on the contributions to the various branches of zoology inserted in Wiegmann's "Archiv" under the editorship of, and some of them compiled by, Troschel, replace in some measure the "Zoological Record" for the German public, and are kept up nearly to the same period, some of the reports for 1870 having already appeared; they are also much to be commended, although they may not have quite the method and completeness of the "Zoological Record." I have further to congratulate science in general on the near completion of the Royal Society's great Catalogue of Scientific Papers, the sixth and last volume of which is far advanced, and likely to be in our hands by the commencement of the next session of the Society.

In Botany, Pritzel's excellent and much-improved second edition of his "Thesaurus" is rapidly going through the press, and brings the repertory of separate botanical works down to the year 1871. Current botanical publications are also generally noticed in various botanical publications, especially the "Giornale Botanico Italiano," edited by Prof. Caruel; the "Flora" of Ratisbon; the "Botanische Zeitung," continued since the death of v. Mohl by A. de Bary; the "Bulletin de la Société Botanique de France," which comprises perhaps the fullest bibliographical review; and the *Journal of Botany*, which promises well under the new and active editorship of Dr. Trimen. But, with the exception of lichenography, the bibliography of which is brought down to the year 1870 in Kreppelhuber's detailed "History and Literature of Lichenology," we have no comprehensive references to Memoirs and Papers published since 1863, the term of the Royal Society's Catalogue, and we feel much the want of an annual summary corresponding to the "Zoological Record."

A work has recently appeared which has naturally attracted much of my attention as being intimately connected with a branch of the science which I have on several occasions taken as the subject of my annual Addresses, and as being the result of long and careful study of the great and varied mass of data collected by its laborious and distinguished author. I speak of Grisebach's "Vegetation of the Earth according to its climatological distribution." The general scope and plan of the work has been recently noticed in an article in NATURE,† and I shall on the present occasion confine myself to a few observations on his views with reference to some of those regions or districts to which I had intended to call your attention in my last year's Address.

One of the most interesting of these regions is the Japanese, or the greater part of Grisebach's Chino-Japanese regions, that is, the Japanese islands and opposite coasts of the Asiatic continent. The peculiarities of its flora have been accounted for, upon considerations depending chiefly on origin, in a well-known paper by Asa Gray (Mem. Amer. Acad. new ser. vol. vi. p. 424), whose views are fully coincided in by Maximowicz and others, but strongly objected to formerly by Miquel and now by Grisebach, who relies upon climatological and other physical considerations. It appears to me that this is a strong instance of the combined effects of the two agents as explained in my abovementioned Address of 1869 (p. 15; Proc. Linn. Soc. 1868–69, p. lxxvii.) The main features of this flora are the mutual intergrafting of northern and tropical types, and the number of highly differentiated endemic or widely dissevered monotypic or almost monotypic races; the former due to physical, the latter to derivative causes.

With regard to the endemic or widely dissevered highly differentiated races (monotypic genera, sections, or very distinct species), Grisebach's views differ widely from those of Asa Gray and other modern naturalists who adopt more or less the theory of evolution. Grisebach, as already observed, entirely ignores community of origin of closely allied or representative species, and is but little disposed to take into consideration ancient dispersion under geological conditions different from the present ones. Each species he believes has arisen—he had formerly said been created, an expression he now abandons in order not to be supposed to prejudge a question which admits of no positive solution—each species has arisen in a particular spot (from what materials he thinks it vain to inquire), under the influence of physical and other external conditions, and has spread more or less in every direction from this birthplace or centre as far as those external conditions have prevailed, and in so far as their progress has been unopposed by insurmountable physical or climatological barriers. In conformity with these views he explains closely allied and representative species in a passage which I give at length for fear of misrepresenting him by an abstract. "The birthplace (*Entstehungsort*) of a plant species," he says, vol. i. p. 515, "may be taken as the most perfect expression of the concordance between the physical life-conditions of the place and the organisation of the plant; for this suitability to given influences of inorganic nature gives the highest measure of the capability of preservation which life strives to attain. Upon these propositions is founded the conclusion, that the nearer the centres of different plants are placed geographically, and the less different are therefore their climatological conditions, the more similar must be their organisation, or, what amounts to the same thing, the more species will have arisen in the same genus. This phenomenon is exhibited in all places where we can compare endemic species whose dispersion is limited, but in islands which have a peculiar vegetation it is less pronounced than in continents. From any one point climate is gradually altered, like the radii of a circle which gradually diverge more and more from each other from the centre to the circumference. In a continent the whole area of the circle may be supposed to be suited to the production of changes in organisation; in an archipelago it is interrupted by the sea, and here, therefore, few similar species have arisen. Another consideration to be taken into account is that genera when compared with each other are unequally susceptible of change (*veränderungsfähig*); their species, therefore, to keep to the same metaphor, will be found arranged at greater or less distances from each other in the radii of the circle. If the area of the continuous land is small, monotypes will have more readily arisen—genera which, on the one hand, are very little or not at all susceptible of change, and on the other hand, can no longer subsist with a certain degree of climatological change. If in a more remote geographical distance the more important climatological conditions which these genera require are repeated, we may, perhaps, find in another part of the globe a second species; and this generally explains the orign of the species which have been termed representative (*vikariirende Arten*). A precisely similar climate, however (exactly the same complication of the very varied phenomenon towards which organisms bear themselves receptively), is never repeated in two distant points of the earth's surface; and this may be taken as the foundation of the absolute unity of centres of vegetation, that is to say, of the proposition that every species in its wanderings has issued from a single birthplace, which does not exclude the possibility of solitary exceptions which might be imagined in plants of less receptivity."

In all this it appears to me that if the writer refuses to admit of a descent from a common parent, we have a right to ask of him what is the previous organisation upon which he imagines climate to have worked to produce allied species in one region and representative species in distant regions? what are the previous genera which have changed? for upon that seems to hinge the whole of his argument in refutation of Asa Gray's hypothesis explanatory of the original connection between the East Asiatic and East American floras. That every species had arisen in one spot, whether by differentiation or by creation, appears now to be tacitly admitted by all. Asa Gray, in accordance with Darwinian theories, supposes widely spread species to have been, under the different conditions of distant lands, gradually modified in different directions, so as to have produced distinct varieties or representative species; Grisebach supposes these different conditions to have independently produced distinct but similar species, by acting on organisms which had not been one and the same species; but what else they may have been he seems to think beyond the reach of plausible conjecture.

* Delivered Friday, May 24, and abridged.

† No. 128, April 11, 1872.

Leaving, however, these questions of origin aside, he strongly objects to the classing representative with identical species in considering geographical distribution; for the former appear in such absolutely dissevered distant regions that an interchange of species, even in early geological periods, seems impossible, as, for instance, in the case of several Ericas of the Cape and of Europe. It is on the contrary, he believes, almost always possible to deduce the actual progress of identical species from the form or physical accidents of their homes and from the means of dispersion at their command (p. 519). He therefore, in combating Asa Gray's conclusion, commences by eliminating from his calculations, after the example of Miquel ("Over de Verwantschap der Flora van Japan met Azië en Noord America, Versl. K. Akad." Amsterdam, ser. 2, ii.), all representative species, thus reducing Asa Gray's list of concordant races in Japan and Eastern North America from 226 to 81, from these Grisebach subtracts 41, which are also inhabitants of Western North America, and can still, he thinks, daily transmit their seeds across the Pacific Ocean; 17 more are, in his opinion, supported by that of other botanists, either certainly not identical or doubtful, and to be added to the already eliminated representative species. Of the remaining 23, he finds 21 which can bear a high northern climate and may yet be found in the Oregon or other imperfectly explored territories of North-West America; and the whole long list is thus reduced to two species only, whose problematical dissevcrance in Japan and Eastern North America remains unexplained—the one, *Elodea petiolata*, being a marsh plant, which as such possesses great migratory powers, the other, *Carex rostrata*, from the White Mountains, awaits further researches on its geographical distribution. Even admitting the possibility of the greater early dispersion of these species in former geological periods propounded by Asa Gray, Grisebach thinks that any such great antiquity of the Japanese flora is not established on so firm a ground as to supersede any attempts at finding other explanations limited to the results of forces still in activity in present times, and that accordingly the distribution of the species in question may be satisfactorily accounted for by the means of dispersion still available, if the data are viewed in the light he has placed them. I should doubt, however, whether his mode of cutting up a long array of ascertained facts further increased by subsequent researches, in order to make them agree with preconceived theories, will carry any stronger conviction into Asa Gray's mind than in my own, more especially as the presumed great antiquity of the Japanese flora is not deduced from these facts alone, but is derived also from other evidences, amongst which the peculiar character of the endemic monotypes bears a prominent part.

With regard to Grisebach's idea that representative and similar species are independently produced by similarity of climatological conditions, and that they afford no conclusive evidence of community of origin, for that they are to be found in widely dissevered localities between which it is impossible to conceive any continuity even in ancient geological periods, and with reference to the instance he adduces of the above-mentioned heaths of the Cape and of Western Europe, I would recall to your minds some remarks I made in my Address of 1869 (p. 25; "Proceedings," p. lxxxvii.) on the remarkable coincidence of several genera, and the near similarity of some species that exists between these two widely dissevered regions. I would now add that if it is difficult to imagine any ancient continuity which should readily explain this phenomenon, it seems equally difficult to account for it by any climatological similarity, if we consider how much Cape plants in general, accustomed to a prolonged summer's sun, suffer from its want in the dull damp seasons of Western Europe.

The Eastern Archipelago, the study of whose fauna, as connected with the history of the great changes it has undergone by successive submersions and upheavals, has been rendered so interesting by the well-known labours of Mr. A. R. Wallace, calls imperatively on the attention of botanists in the search of facts derived from its flora in confirmation or refutation of these views. Unfortunately we are in this respect very much in arrear. The botany of New Guinea is almost wholly unknown; and from Celebes we have but very little. Sumatra, Java, the Philippines, Timor, and a part of Borneo, have been more generally explored, and large collections of their plants have been deposited, chiefly in the Leyden Herbarium, but also in considerable numbers in those of Kew and in some others; but even these materials have been but little worked up in a manner to be available for the geographical botanist. The two eminent Dutch botanists who had successively charge of the Leyden collections contributed much in various ways to the progress of the science and especially to our knowledge of the flora of the principal Dutch islands, but without leaving any satisfactory general view of all that was known on that of the whole archipelago. Blume's "Bijdragen tot de Flora van Nederlandsch Indië," drawn and published at Batavia when he was still very young, was a wonderful work considering the means at his disposal; and after his return to Europe he commenced elucidating with equal ability and in greater detail several orders connected with that flora ("Flora Javæ," "Rumphia," "Museum Lugduno-Batavense"); but as general works all these remained incomplete. Miquel drew up a "Flora Indiæ Bataviæ," purposing to be complete as far as his materials allowed; but it was far too hastily compiled, without the necessary critical examination of genera and species. Since his lamented death I have seen no signs of any Dutch successor likely to take up the study of the botany of the archipelago in any scientific point of view. In the meantime the rich stores collected by P. Beccari in Sarawak are, I am informed, in the course of distribution; and that enterprising Italian naturalist has returned to the East with a view to the exploration of New Guinea and some others of the less known islands.

Grisebach, in his Indian Monsoon region, unites the archipelago with the East Indian peninsulas and continent to the foot of the Himalayas, the Island of Ceylon to the west, and the Society and the Marquesas and other coral islands to the east, embracing, as it were, the whole of Tropical Asia or Sclater's Indian, with a portion of his Australian Palæotropical regions; and certainly a cursory survey of the vegetation of this vast expanse of territory would appear to justify Grisebach's idea of its unity of character. It has also tolerably definite limits determined on the north-west by the drier rocky East Mediterranean or Persian region, on the north by the great Himalayan chain, and on the east and south by a wide extent of ocean; the exceptions being chiefly the above-mentioned innoculation, as it were, into the Japanese flora to the north-east, and more or less of an intrusion across the ocean to the westward into Tropical Africa, and over a narrower interval of sea to the south-east into north-east Australia. The principal cause of this uniformity of character, so far as it goes, is well deduced by Grisebach from climatological and physical conditions, his observations on the chief portion of the region, or East India proper, from Ceylon and the Peninsula to Malacca, being mainly derived from Hooker and Thomson's most instructive introduction to their "Flora Indica," which, from a variety of causes, was unfortunately put a stop to after the issue of the first volume. It is now being replaced by the "Flora of British India," under Dr. Hooker's editorship, of which the first part, just published in a more concise form, gives a confident hope that it may be steadily and rapidly brought to a conclusion. We shall then have ample means of instituting a comparison of the Indian vegetation with that of Boissier's "Flora Orientalis" to the north-west, of Ledebour's "Flora Rossica" to the north, of Miquel's almost as complete, though less methodical enumerations of Japanese plants to the north-east, of the "Flora Australiensis" to the south, and of Oliver's "Tropical African Flora" to the west.

The "Flora Indica" does not, however, extend to the eastern portion of Grisebach's Monsoon region, about which our information is so deficient; but where, as he observes, "the distribution of organisms involves one of the most remarkable problems in the darker regions of vegetation-centres." He further remarks that the flora of this eastern region, with the exception of the Timor group, is everywhere Indian, and regulated by climatological conditions, the vegetation of New Guinea being, as he rather hastily supposes, "thoroughly similar to that of Borneo," a result quite at variance with the distribution of animals as expounded by Wallace. As a possible explanation of this discrepancy, he proposes an hypothesis which, for fear of misrepresentation, I shall give at length:—"Thus the limits of particular forms of plants and of animals in the Indian Archipelago do not concur. Vegetation corresponds to climatological, the fauna to local (*räumliche*) analogies. This opens a wide field for speculation on the history of the globe. By a mere sinking of the land to an unimportant extent, Darwinism readily explains the origin of the fauna of these islands, but not the Indian character of the flora of New Guinea, which presupposes much greater upheavals than the origin of fauna, calculated to give rise to equatorial rainy seasons. This hypothesis would derive the endemic marsupials of New Guinea from the Australian ones after the establishment of the Torres Straits, but it gives no ex-

planation of the way in which the peculiar palms of New Guinea could have arisen from allied Indian genera. With more plausibility, although with little more foundation on ascertained facts, may be put forward another conjecture derived from the respective relations of plants and animals to the outer world. From their organisation the former are much more dependent on climate, the latter on the vegetation which serves them for food. If an extent of sea is converted into land, its climate (independently of its geographical position) will depend on the form of its coasts and on the relief of its surface. If, now, creative forces are pronounced, the forms of vegetation will be suited to the climate. These forms correspond to the climate of the present day, as everywhere else, so also from the Malayan continent to the South-Sea Islands. If we assume that in an earlier geological period the eastern portion of the Archipelago did not yet possess its mountains, and was connected with Australia, so might the Australian climate have then extended to the Archipelago; but with the change in the climate the vegetation of the time must have disappeared. A new flora arose; but in the fauna, which was less dependent on climate, the earlier types may have longer persisted. Perhaps the present period may be regarded as one in which the Australian forms of animals are in an expiring state, because the jungle-forests do not sufficiently correspond to their demands for food. It would appear as if creative activity only wakes up at specific points of time on specific points of the earth's surface, and that during the long pauses Nature's struggles are directed only to the retaining that which exists. Vegetation, as well as the animals which it feeds, must ever be considered in relation to the geological developments. During the time which has elapsed since the mountains and the moist climate of New Guinea have been established no new creation of Mammalia has taken place. Only very few Marsupials, and scarcely any other Mammalia, have been found on this great island. But in other classes of animals forms have arisen corresponding to the present vegetation, such as the Birds of Paradise, which are unknown in Australia, but which in New Guinea hover over the forest tree-tops, whilst they can take shelter from the mid-day sun under the dense foliage. . . . The present type of organisation was already cast in New Holland in the tertiary period, whilst the endemic plants and animals of New Guinea appear to be of much later origin" (vol. ii. pp. 69, 70).

Without admitting to its fullest extent the main fact relied upon, that there is no marked line separating the vegetation of the western and the eastern portions of the Archipelago corresponding to that laid down by Wallace for animals, a premature conclusion in the present state of our knowledge,* and still less entering into speculations as to the intermittent action of creative forces which I do not quite comprehend, we must agree with Grisebach that, so far as shown by the scanty data at our command, the uniformity is much greater in the botany than in the zoology of the whole Archipelago. We may also admit with him that this comparative uniformity may be, in great measure, due to the uniformity of climate acting more upon plants than upon animals. But there are other circumstances which may probably have favoured the continued action of natural selection through countless ages in procuring this result. Dr. Hooker has very plausibly suggested a greater geological antiquity in the plant races than in those of animals, especially the higher animals, under which the former, or the ancestors from which they are descended, had become established over a wide extent of continuous land before its successive disruption, upheavals, and depressions producing the present isolation. We must next take into account that this continuity of land need not be so great in the case of plants as of animals. The dispersion of the former is passive, and takes place chiefly in a dormant state, in which minuteness and enormous multiplication afford them opportunities for crossing seas and other barriers denied to the higher animals. Plant races of accommodating (*accomodationsfähiger*) constitutions, as they successively arose and attained the full vigour of specific life, will have early spread over any continuous or but little broken area, enjoying comparatively similar physical and climatological conditions, the western and eastern forms intermingling, so as that the one should only gradually be replaced by the other, thus in early ages repeating under the tropics the phenomenon now observed in the northern temperate Europeo-Asiatic region. These vigorous or accommodating races, whether new differentiations or foreign invasions, will at the same time have gradually expelled and replaced races which in tertiary or other previous periods had occupied the land under different conditions, and which now could only maintain themselves in the struggle for life in localities affording them, in their reduced or weakened state, special protection against the effects of the altered climate and the attacks of their vigorous competitors. Such localities, suited to ancient or expiring races of few individuals, with varied but always special requirements, and generally slow of propagation, may be exemplified in the Mediterranean, the Japanese, and other regions abounding, as Grisebach terms it, in centres of vegetation; they may be faintly traced in the Nilgherries and in Ceylon; but are in general very few in Grisebach's Monsoon region, and those few are as yet but little known or wholly unvisited. Kini-Balu, in Borneo, has, however, as we learn from Dr. Hooker, supplied a place of refuge for a certain number of Australian types, and it may be conjectured that many more may have maintained themselves in those lofty mountains of New Guinea which have as yet been only seen from a distance. Continuity of vegetation probably existed in tertiary times between Australia and a vast extent of land including more or less of both of Wallace's divisions of the Archipelago. How far subsequent changes which have influenced the present distribution of animals may have affected that of the forest vegetation, can only be judged of when the floras of Borneo, Celebes, and New Guinea shall have been as well investigated and compared as have been those of Sumatra and Java.

* Dr. Hooker has, for instance, remarked that no Dipterocarpeæ have been found to the east of Borneo.

(*To be continued*)

SCIENTIFIC SERIALS

In the *Journal of Botany* for May the editor, Dr. H. Trimen, describes a species of *Luzula* new to the Flora of Europe, *L. purpurea* Link, of which a drawing is given.—Mr. J. G. Baker concludes his revision of the Cape species of *Anthericum*.—Mr. Archer Briggs notices some peculiarities of the botany of the neighbourhood of Plymouth, principally with reference to species common elsewhere which are absent from the south-western extremity of our island.—Mr. O'Meara continues his researches on Diatomaceæ.

The number for the present month opens with a note on Dimorphism in *Eranthemum* by Mr. John Scott.—The other original articles are Notes on British Gentianaceæ by Mr. James Britten, and Supplementary Notes on the *Erysiphei* of the United States by Messrs. Cooke and Peck. Several valuable reprints, as well as many interesting short notes and queries, also appear in both these numbers.

The *Canadian Naturalist*, vol. vi. No. 3, is almost wholly devoted to Geology, commencing with a continuation of Principal Dawson's series of papers on the Post-pliocene Geology of Canada, the portion of the subject specially treated of in this number being the local details.—Prof. Sterry Hunt's "History of the names Cambrian and Silurian in Geology" has already been reprinted in our columns.—Mr. E. Billings contributes some "Remarks on the Taconic Controversy," in which he defends the views of Dr. Emmons with regard to the position of these rocks, and a note on the genus *Obolellina*.—The only new geological article is Prof. Smallwood's "Meteorological Results for Montreal for the year 1871.

SOCIETIES AND ACADEMIES

London

Royal Society, May 30.—"On the Structure and Function of the Rods of the Cochlea in Man and other Mammals." By Urban Pritchard, M.D.

The aim of this paper is to describe the true construction and use of the cochlea, so far as its task of distinguishing the various sounds is concerned. This cochlea, it must be borne in mind, consists of a spiral canal, in form and shape very similar to the inside of a snail-shell. From the axis of this spiral there proceeds horizontally a plate of bone, the *lamina spiralis*, almost dividing this canal into two. From this plate again there extend two membranes, the membrane of Russner, and the Lamina

spiralis membranacea, as far as the walls of the canal, thus separating it into three minor canals.

Between the layers of the membranous spiral lamina are situated the so-called rods of Corti. These were first discovered and described by the Marquis de Corti; and although since then many observers have studied the subject, yet scarcely two investigators are agreed as to their exact form.

In a general view of the rods from above, they appear similar to two rows of pianoforte-hammers, rather than like the keys of that instrument, to which they have been likened. In a lateral view, these two rows of rods are seen sloping towards each other, like the rafters of a gabled roof. The rods consist of a shaft and two enlarged extremities, but the two rows differ considerably in form; the inner rods are attached by their lower extremities to the membrana basilaris at its junction with the lower lip of the limbus, and just external to the spot where the nerve-filaments emerge. They are directed outwards and upwards, with a slight undulation to meet the outer rods. The lower extremity is enlarged and rounded, gradually tapering to the shaft, which is cylindrical; the upper extremity is somewhat cuboid in form, but the outer surface is deeply concave, and the upper lip of the concavity is prolonged into a process.

The outer rods are attached to the membrana basilaris by a broad base, which also gradually tapers to a cylindrical shaft. Their upper extremity is less cuboid in form, and presents a convex internal surface, which articulates with the corresponding concavity in the inner rods just mentioned; from the outer and upper part there extends outwards a slender process.

One of the most important features with regard to these rods is their relative length. Most authors state that there is very little difference in the length of the two rods; in this, however, they are much mistaken; for not only do the two sets of rods differ in this respect, but the length of each varies according to its position on the cochlea. Thus, at the base, the outer rods are as nearly as possible equal in length to the inner, but proceeding upwards, both rows increase in length with great regularity, although not in the same ratio, the outer increasing with much greater rapidity, so that near the apex they are twice the length of the inner.

It was generally supposed, *a priori*, that these rods were graduated so as to distinguish the most minute variation of tone, but no one until now has been able to demonstrate this.

The rods, therefore, vary in length from about $\frac{1}{500}$ to $\frac{1}{200}$ of an inch. The number of rods in each row is not the same, there being about three of the inner to two of the outer, and, according to calculation, there are about 5,200 inner rods and 3,500 outer in the whole cochlea.

Corti and most other authors considered this system of rods to be the essential portion of the cochlea; they supposed the rods received the vibrations conducted to them, and being set in motion, so affected the nerves as to cause the brain to appreciate the various sounds. Later German writers have attributed the appreciation of the various vibrations to certain delicate cells, which are attached to the under surface of the membrana reticularis. From this circumstance alone it appears very evident that these investigators had not suspected, much less discovered, the fact that the rods are most exquisitely graduated, for otherwise they could surely never have doubted that so beautiful and suitable an apparatus could have any other ostensible purpose than that of appreciating the various sounds. I consider indeed that the cochlea represents a musical instrument, similar in nature to a harp or musical box, the strings of the one and the tooth of the other represented by the rods of Corti. The spiral bony lamina is simply a sounding-board; around the rods are placed the various nerve-cells and nerve-fibres, and from these cells the impressions are conveyed by the fibres to the brain itself.

It is possible, therefore, to trace very completely the course of sounds or vibrations from a musical instrument or any other source to the brain, through the medium of the ear. First the vibrations are caught and collected by the auricle, and transmitted through the external meatus to the drum of the ear, next across the middle to the internal ear. Here the sound is appreciated, merely as a sound, by the vestibule; the direction is discovered by means of the semicircular canals; but to distinguish the note of the sound, it must pass on to the cochlea. The vibration therefore passes through the fluid of the cochlea and strikes the lamina spiralis, which intensifies and transmits the vibration to the system of rods. There is doubtless a rod not only for each tone or semitone, but even for much more minute sub-divisions of the same; so that every sound causes its own particular rod to vibrate, and this rod vibrating, causes the nerve-cells in connection with it, to send a nerve-current to the brain.

"Examination of the Gases occluded in Meteoric Iron from Augusta Co., Virginia." By J. W. Mallet, Ph.D., M.D.

The author stated that, whether or not his analysis be considered as furnishing presumptive evidence of the Virginia iron having come to our earth from a different atmosphere to that of which the Lenarto meteorite brought us a sample, the result differs so far from that of our sole previously recorded determination of the kind as to make it a matter of much interest that a larger number of meteoric irons from various localities should be subjected to careful examination in the same direction, thus supplementing our knowledge of the fixed constituents of these curious bodies by a study of their gaseous contents.

Anthropological Institute, June 3.—Sir John Lubbock, Bart., president, in the chair. "The artificial enlargement of the Ear-lobe in the East," by J. Park Harrison; "On Tumuli at Sapolia, Ardaschevo, Russia," by Baron de Boguschefsky; "On Ogham Pillar Stones in Ireland," by Hodder M. Westropp; and "The Westerly Drifting of Nomades from the 5th to the 19th century, Part 9: the Fins and some of their allies," by H. H. Howorth. The object of the paper by Mr. Howorth was, in the first place, to discriminate between the Fins and the Lapps, whose history, physical features, customs, and other idiosyncracies are entirely different. In the second place, to show that the Esthonians belong to the Fin rather than the Lapp stock. Then to adduce the evidence for making both Fins and Esths very recent emigrants into their respective modern habitats, and to trace them to their former country beyond the Dwina, where they were known to the Norsemen as Biarmians, and to the early Russian chroniclers as Sarvalokian Ichudes. Having divested Scandinavia and Esthonia of their Fin inhabitants, and having thrust them back into an area which was of great renown in the times of the Norsemen, we can explain how the civilisation, which the Kalevala and other evidence proves, was once peculiar to the Fins, has been lost, and also explain whence the Norsemen derived a great portion of the culture which distinguished them. The main position that was new in the paper was the deriving the Esthonians from the same area as the old Fins, and making them also to be recent emigrants, and not Autochthones, as they have been so frequently described; and the clearing up of the ethnography of the old province of Biarmia, which has hitherto been much confused.

Victoria Institute, June 3.—The Rev. Prebendary Irons read a paper on Prof. Tyndall's "Fragments of Science for Unscientific People." He first dealt with physical science and its rivalries, Dr. Irons holding that there was a want of thoroughness in Prof. Tyndall's appeal to facts. He then analysed the statements made as to the action of matter on matter, and considered Dr. Tyndall to be inconsistent in stating that science could not solve the problem of the Universe, and yet adding that we ought not to see the evidences of Divine pleasure or displeasure in the phenomena of the material world. Finally, Dr. Irons urged that science and true religion could not be supposed as opposed to each other, as some men of science would have us believe.

CAMBRIDGE

Philosophical Society, May 27.—"On some properties of Bernoulli's numbers, and, in particular, on Clausen's Theorem respecting the fractional parts of those numbers," by Prof. J. C. Adams. The author gave a comparatively simple proof of Clausen's theorem. Thirty-one of Bernoulli's numbers are already known; the author has calculated twenty-two additional numbers. He also had proved that if n were a prime number other than 2 or 3, the numerator of the n^{th} Bernoulli's number was divisible by n.—"On some of the Symptoms produced by Uræmic Poisoning in Chronic Disease of the Kidney," by Dr. Latham. These symptoms were explained by:—1. The impeded passage of the blood through the minute arteries of the system, caused by excessive contraction and hypertrophy of the muscular walls of these vessels, as has been demonstrated by Dr. George Johnson. 2. The hypertrophy of the heart, developed by the resistance offered to the circulation from the contraction of these small arteries. 3. The impoverished state of the blood, which is the necessary accompaniment of the disease.

CANTERBURY

East Kent Natural History Society, May 2.—"Remark-

able objects found in the Suffolk Crag, and simulating human workmanship." Some time since the president had received from the Rev. W. Bird some perforated shark's teeth; but it was only an hour or two before the meeting that a box arrived containing a further collection, including many remarkable fossils from the red clay diggings of that district, the whole being specimens of the admirable series of such objects in the possession of Mr. Edward Charlesworth, F.G.S. The teeth were described as belonging to the genera *Otodus* and *Carcharodon*, and each of these teeth had a hole near its base, about a sixth of an inch in diameter, like in form and position to the holes which the South Sea Islanders make in the teeth of sharks at the present day in order to the formation of necklace ornaments. Of course, should the perforations in the teeth from the Suffolk Crag prove to have been the work of man, it would suggest that he had existed on our planet an immense time before that at present fixed as his original appearance here. But though these holes are such as might have been, and most probably were, made by human agency; they might, on the other hand, have been the work of some boring sponge, worm, or mollusc, especially as there are in this last class many species with a curious file of lingual teeth composed of silex; and even at the present day there is a complete mystery as to the means by which some invertebrates bore into and through very refractory substances. However, the whole evidence as to these holes in the shark's teeth preponderates in favour of the view that they were made by man. But even fully admitting that they were so made, it would not necessarily follow that the perforations in the teeth were made by man coeval with the crag in which they were found.

PHILADELPHIA

American Philosophical Society, February 16.—A memorial to Congress was adopted, praying for an appropriation in aid of astronomical expeditions, especially for one to the Antarctic region, for the purpose of observing properly the approaching transit of Venus.—Prof. P. E. Chase read a paper "On Correlations of Cosmical and Molecular Force." From the hypothesis that the entire energies of opposing attractive and repulsive forces may be considered as concentrated in one of the foci of the resulting oscillations, he deduced various interesting approximations to the ratio between the respective amounts of heat required for equivalent work under constant volume and under constant pressure, to the change of specific gravity in the conversion of $H_2 + O$ into H_2O, to the period of terrestrial rotation, and to the solar and lunar masses. Some idea of his method may be formed from the following approximation to the sun's mass and distance. According to the mean result of experiments by Dulong, Hess, Andrews, and Favre and Silbermann, one pound of H burned with eight pounds of O liberates enough heat to lift the nine pounds H_2O vapour, *in vacuo*, $\frac{34533 + 772}{9}$ feet. Such a lift would establish an oscillation, which would be perpetually sustained, by terrestrial attraction, and elastic rebound, unless otherwise counteracted. If chemicals vary as gravitating energies, the mean height of the oscillating vapour : mean height of oscillating earth :: earth mass : sun's mass. Therefore, if m = mass of sun ÷ by mass of earth, d = distance of sun ÷ earth's radius, r = earth's equatorial radius in feet, h = mean height of oscillating vapour, T_1 = solar year in seconds, T_0 = time of satellite revolution at the surface of the earth.

$$m = \frac{dr}{h}$$

$$T_0 = T_1\left(\frac{d^3}{m}\right)^{\frac{1}{2}} = T\left(\frac{hd^2}{r}\right)^{\frac{1}{2}}$$

Hence we readily obtain the values

$$d = 233{,}772 = 92{,}639{,}500 \text{ miles}$$
$$m = 350{,}260.$$

—Benjamin Smith Lyman read a paper "On the Topography of the Punjaub Oil Region." It aimed at a somewhat detailed account of the topography of the Punjaub Oil Region: its situation, general features, special features, &c. The different places are mentioned where each kind of topography is to be seen, and its causes and simple laws pointed out, chiefly in order to show the great usefulness of careful topographical studies to geology. A short sketch of the geology of the region, apart from structure, is also added; as to the oil, from the writer's own "General Report on the Punjaub Oil Lands, Lahore, 1870," and as to other points from older works. The general section of the rocks of the region is as follows, below the new and old alluviums:—

Miocene (Sivalik), perhaps	3,000 feet.
Eocene (Nummulitic), with oil ...	1,950 ,,
Mesozoic, perhaps	700 ,,
Carboniferous, without oil, about ..	1,800 ,,
Devonian, with salt and plaster ...	2,850 ,,
	10,300 ,,

The oil or asphalt (dried oil), or rock tar (melted asphalt), is found at a dozen different places, and, in very small traces, at half a dozen more, all within a space of a hundred miles square. They are all in Nummulitic rocks, except one in Carboniferous. The deposits all seem of very small horizontal extent—sometimes only a few feet, seldom a hundred yards, once only as much as half a mile. In this case, too, the oil-bearing bed is a hundred feet thick, in one other forty, in two others twenty, and in the rest much less. The oil comes in some places from lime rock, in others from sand rock, or shales. The yield of one well was at first fifty gallons a day, but grew quickly less, like the ordinates of a parabola, and seems likely to reach 3,000 gallons in all within a year and a half. At a rough guess, a hundred such wells might be bored in the region, with a whole yield, then, of hardly 7,000 barrels. The natural springs (five) yield from a gill to three quarts a day. The oil is dark green and very heavy (25° B. or less). There is nothing whatever in the Punjaub oil deposits to bear out a belief in the distillation of oil from one bed to another, or in its emanation from below, or in its gradual passage from the lower parts of a bed to higher parts of the same bed, or in its origin from any source but the decomposition of organic matter in the rocks. Neither is there anything here (or anywhere else) to justify wild hopes of finding large quantities of oil by boring into cavities below the oil-bearing bed. The occurrence of salt, gypsum, and alum shales in large quantities is noticed, as well as that of sulphur, saltpetre, brown coal, and good in small quantities, and that of traces of copper, iron, and lead.—Prof. E. D. Cope read a paper on *Bathmodon*, a genus of extinct Ungulates. It was presented as Perissodactyl in general characters, but with peculiarities of dentition of a combined ruminant and suelline character. There was on the outer side of the molars but one crescent, and before this a tubercle. The inner portion of the crown a ledge. Besides the species *Bathmodon radians*, a second form, *Loxolophodon semicinctus* was referred to the group. The former animal was large as the rhinoceros, the second equal to the tapir.—A memoir on the "Geology of Western Virginia" was presented by Mr. J. J. Stevenson.

March 1.—Mr. B. Smith Lyman presented for publication a topographical map of West Virginia.—Prof. Cope read a paper on two new species of Ornithosaurians from the Kansas Cretaceous. They were described as *Ornithochirus umbrosus* and *O. harpyia*. The former was regarded as one of the most gigantic of the pterodactyles, extending probably 25ft. from tip to tip of the wings. The other was two-thirds the size.—Prof. Cope read a paper on *Protostega*, a genus of extinct Testudinata. A detailed account of the Osteology of *P. gigas* from the Cretaceous was given, by which it appeared that the genus had separate ribs as in *Sphargis*, and that the only carapace was formed by large radiating plates of bone in the skin. Two other species were described, *P. tuberosus* and *P. neptunius*—the last, the largest known marine turtle.—Mr. Eli K. Price read a paper on "Some other Phases of Modern Philosophy," in which he combatted the views of Huxley and others as to the physical basis of life.

PARIS

Academy of Sciences, May 20.—M. Becquerel read a ninth memoir on the means of increasing the effects of electro-capillary actions in inorganic bodies, and on the effects of the same kind produced in living organised bodies.—M. Sainte-Claire Deville presented a note by M. G. Guéroult on the relations existing between the numbers of vibrations of musical sounds and their intervals, and on a scale-rule for acoustic calculations invented by him.—M. Jamin communicated a note by M. J. M. Gaugain on the electro-motive forces developed by the contact of metals with inactive liquids, in continuation of a former paper by the same author; and M. T. Du Moncel presented a note on the induced currents resulting from the action of magnets upon induction coils normally to their axes.—A memoir was read by M. Le Verrier on the theories of the four superior planets, Jupiter, Saturn, Uranus, and Neptune, containing an investiga-

tion of the perturbations which each of these four planets undergo by the action of the other three.—A letter was read from Father Secchi, containing a summary of observations of solar protuberances from Jan. 1 to April 29, 1872, containing a tabular exposition of the results of observations, with a discussion of their bearing upon the general question.—M. Delaunay presented an extract of a letter from M. Forster on the magnetic disturbances observed during the occurrence of auroras.—M. Coste communicated a note by M. Z. Gerbe on the segmentation of the cicatricula in the ovum of plagiostomous fishes, in which the author describes the evolution of the Rays in confirmation of the opinion put forward by M. Coste that in the plagiostomous fishes, as in reptiles and birds, it is the cicatricula alone that undergoes segmentation. M. Coste also communicated a notes by M. G. Pouchet, on blue colorations in fishes, in which the author ascribes the blue colours presented by some parts of certain fishes to the presence beneath the skin of oval or roundish bodies which he calls "iridising bodies."—A note by M. E. Prillieux, on the influence of congelation upon the weight of vegetable tissues, was presented by M. Duchartre.—M. A. Rivière read a memoir on the oolitic or Jurassic formation of La Vendée, accompanied by a geological map of that locality.—M. H. Douvillé presented a note on the coal-bearing strata of the banks of the Rhine, with especial reference to the distribution of these deposits into an upper and lower formation, the deposition of which was separated by a great dislocation.—M. S. Meunier presented a mineralogical investigation of the grey serpentines, from which it results that these rocks consist essentially of a mixture of magnetite, pyroxene, peridot, and magnesite.—M. A. Leymerie communicated a note in reply to a recent communication by M. Garrigou on the unity of composition of the Pyrenees.

May 27.—M. Serret presented a memoir by M. V. J. Berton on the determination of the limits between which a primary number of a given form occurs.—M. Chasles presented a note by Mr. A. Cayley on a flattened quartic surface; M. Ribaucour a note on the developates of surfaces.—A note by M. C. Jordan on the infinitely small oscillations of material systems was presented by M. Yvon Villarceau.—M. Faye presented a reply by M. Respighi to a recent note by Father Secchi on some peculiarities of the constitution of the sun.—M. Le Verrier communicated a note by Father Denza on meteors observed in Piedmont on the evening of April 24, including the account of a second meteor in addition to that seen at Agde by M. Perris. The author also notices the occurrence of a fine aurora on May 9.—M. Becquerel read a note on the cultivation of the vine in clay soils, in which he indicated the conditions of temperature prevailing in clay, silicious, and calcareous soils, and showed that in the former the vine could only be successfully cultivated by training it to a considerable height.—M. W. de Fonvielle presented a note embodying some fresh examples of the danger arising from the vicinity of metallic masses during storms, and M. E. Nasse forwarded a note on an instance of globular lightning observed at Brives on May 17.—M. Delaunay presented a note by M. Frou on the laws of cyclones and tempests, and on their geometrical representations.—A considerable number of papers on chemical subjects was presented, namely, a memoir on the iron contained in the blood and in food by M. Boussingault, containing a great number of interesting details upon this important subject; a note by M. A. Wurtz on an aldehyde-alcohol, $C^4 H^8 O^2$, which he proposes to name *aldol*; a note by M. G. Bouchardat on a new organic base, dulcitamine, $C^{12} H^{15} NO^{10}$, derived from dulcite, presented by M. A. Wurtz; a note by M. T. Schlœsing on the influence of vegetable mould on the mobility of soils, communicated by M. Peligot; a memoir by Mr. F. Crace-Calvert on bleaching powder, presented by M. Balard; a note by M. B. Rénault on a new process for obtaining reproductions of drawings, also presented by M. Balard; and a note by M. Sidot on the production of a crystallised phosphuret of iron, presented with some remarks by M. Daubrée.—M. Cl. Bernard communicated a paper by M. Z. Pupier, containing an experimental demonstration of the action of spirituous beverages upon the liver; the author's experiments were made upon fowls and rabbits.—A note by MM. N. and E. Joly on the supposed Crustacean, on which Latreille founded the genus *Prosopistoma*, was presented by M. Milne-Edwards; the authors show that this animal is a true insect probably allied to the Ephemerina.—M. Blanchard communicated a note by M. S. Jourdain on the anurous Batrachia with large and small tadpoles, in which the author insists upon an analogy between the development of the former and that of insects.—M. de Vibraye communicated a note on the spontaneous appearance in France of exotic forage-plants consequent on the presence of the belligerent armies in 1870-71.—M. P. Gervais presented a note on the mammalia of which the bones are associated with the deposits of phosphate of lime in the departments of Tarn-et-Garonne and the Lot. These bones appear to belong to various epochs, the oldest belonging to the fauna of the Paris gypsum, others to the Miocene or more recent times. The genera represented are *Anoplotherium*, *Dichobune*, *Entelodon*, *Cainotherium*, *Amphitragulus*, *Palæotherium*, *Rhinoceros*, *Hyænodon*, *Canis?* (*palæolycos*, sp. n.) and *Viverra?* (*ambigua*, sp. n.) At Caylux there are Rodents allied to *Theridomys*, with remains of *Chalicotherium*, *Anthracotherium*, and *Antilope? boodon*.—M. Daubrée made some remarks on the deposits from which the fossils noticed by M. Gervais are derived.—M. de Verneuil read a note on the recent eruption of Vesuvius, which also formed the subject of a communication from M. Guiscardi.

BOOKS RECEIVED

ENGLISH.—Experimental Chemistry, founded on the work of Dr. J. A. Stockhardt: C. W. Heaton (Bell and Daldy).—Knapsack Manual for Sportsmen in the Field: E. Ward (Bradbury and Evans).

DIARY

THURSDAY, JUNE 6.

ROYAL INSTITUTION, at 3.—On Heat and Light: Prof Tyndall, F.R.S.
SOCIETY OF ANTIQUARIES, at 8.30.—Excavations at Rome, 1871-2: J. H. Parker, C.B., F.S.A.
LINNEAN SOCIETY, at 8.—On some recent forms of *Lagenæ* from Deep-Sea Dredgings in the Japanese Seas: F. W. O. Rymer Jones.—On the Cutaneous Exudation of the Water Newt (*Triton cristatus*): Miss Eleanor A. Ormerod.
CHEMICAL SOCIETY, at 8.

FRIDAY, JUNE 7.

GEOLOGISTS' ASSOCIATION, at 8.—On the Classification of the Cambrian and Silurian Rocks: H. Hicks.—On the Silurian Rocks of the English Lake District: Prof. A. Nicholson, M.D.

SATURDAY, JUNE 8.

GOVERNMENT SCHOOL OF MINES, at 8.—On Geology: Dr. Cobbold, F.R.S.

MONDAY, JUNE 10.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.

TUESDAY, JUNE 11.

PHOTOGRAPHIC SOCIETY, at 8.—On some early Glass Pictures produced by the late Sir John Herschel, Bart.: Prof. A. S. Herschel, B.A., F.R.A.S.—On the Photographic Manipulations undertaken at the last Eclipse, practically described: Capt. Waterhouse, Assistant Surveyor General of India.—Spectroscopic Observations in connection with the Carbon Process: Lieut. Abney, R.E.—On the Use of Uranium in Dry Plate Photography: Colonel Stuart Wortley.

THURSDAY, JUNE 13.

ROYAL SOCIETY, at 8.30.
SOCIETY OF ANTIQUARIES, at 8.30.
MATHEMATICAL SOCIETY, at 8.—On the Surfaces divisible into Squares by Curves of Curvature: Prof. Cayley.—On Prof. Cremona's Transformation between Two Planes and Tables relating thereto: Mr. S. Roberts.—On a Manifold Correspondence of Two Planes: Dr. Hirst.

THE BRITISH MUSEUM

THE Return published by order of the House of Commons on April 19, 1872, of the progress made in the arrangement of t' e collections, and of the objects which have been added during the past year to the National Museum, is a document which, although only seen by a very few persons, cannot fail to be of interest to a very large proportion of English people, and also to those engaged in scientific pursuits all over the world.

Confining our attention to the Natural History Department, and commencing with Prof. Owen's general report, we find that, although every care has been taken on the part of Heads of Departments to limit in all possible ways by declining or postponing all acquisitions not absolutely and immediately pressing, the annual tide of new specimens still flows in, and during the past year 15,879 specimens have been added to and incorporated with the present crowded series.

Everywhere throughout Prof. Owen's report the old grief of "want of space" is introduced and persistently pressed upon the attention of the Legislature; but at the same time allusion is also constantly made to the time when the requirements for increased exhibition-space, and more adequate store-rooms and cabinets, will have all been met by the galleries of the new Museum.

We are glad to see that Prof. Owen puts forward other very good and sound reasons, besides the mere overcrowding, in favour of a speedy release from the too-restricted galleries and studies to which the collections under his care are at present restricted. "Inadequacy of space," writes the Superintendent, "is associated with loss of time." Thus: "To meet the wishes and expectations of scientific visitors and students in regard to opportunities of study and inspection of specimens relating to the latest advances in natural history, the well-filled or crowded exhibition-galleries and cases have to undergo more or less of re-arrangement with removal and interchange of specimens, in order to allow place and access to the novelties."

Again, in the case of the delicate and brittle specimens, the risk which is now incurred in frequently shifting these will then be reduced to its minimum, and, consequently, the chances of preserving such treasures will be greatly increased. It now not unfrequently happens that an entire series of objects have to be removed and rearranged to gain a few feet or even inches of space in some cases.

All this labour and care in the re-adjustment of series, which would be needless if there were abundance of exhibition space, will be removed in the new Museum, and the same amount of labour can be devoted to the more satisfactory task of classification and the true advancement of Natural Science.

Prof. Owen gives in a tabulated form the annual additions made to each Department during the twelve years from 1859-70. The total increase for each is as under:—

	Zoology	Geology	Mineralogy	Botany	TOTAL
Total increase for 12 years..	435,492	78,434	24,945	123,409	662,280*

* The total numbers are wrongly cast in the printed return.

Of course, in certain years the increase in one or other of these Departments has been specially large; thus in 1863 98,754 specimens were added to the Zoological Department, whilst in the following year only 7,688 specimens were acquired. After all, numbers only convey a very imperfect idea of increase, so much depends upon the size of objects themselves. Thus, for instance, a collection of Coleopterous insects, comprising many thousands of examples, may all be contained in a small cabinet of twenty drawers; whilst a tapir, antelope, or other quadruped may when stuffed need a case all to itself, or a whale may require an entire gallery 90ft. long for its proper display. We are glad to hear that the birds and shells are better off for room than the other Natural History divisions; we have always felt when passing through this gallery with its fine series of table-cases, and the birds occupying the wall-cases, that these two groups were specially favoured; whilst the adjoining mammalian-saloon but very inadequately represented the actual exhibition needs of the higher animals. All this Prof. Owen tells us will be set right in the new Museum.

The use of methylated spirit for the preservation of Reptilia and fishes has produced in some cases injurious results to some of these specimens. Dr. Günther will, no doubt, speedily remedy this mischief, and the purer medium must in future alone be used. All the other collections are reported as in good preservation.

There is a long list as usual of additions to each of the Departments. Dr. Gray reports a fine series of Lemurs from Madagascar; a *Grampus Rissoanus*, and a Pike whale (*Balænoptera rostrata*), from the English coast. Various Mammals from Abyssinia, chiefly of the Antilope family. Among the Birds we find Pheasants, Hornbills, and Pigeons, and many lesser members of the feathered tribe. Fishes, Reptiles, Mollusca, and tribes of Insects, have also been added, likewise specimens of the "Glass-rope-*sponge*" (called a "Coral" in the Report), the *Hyalonema* from Japan, and the beautiful vitreous sponge, the *Pheronema Grayi*, from the coast of Portugal. Making a total in all of 10,577 specimens added during the past year to the Zoological Department.

Of Fossils there seems to be a goodly supply. From the La Plata come bones of the *Toxodon*, *Mylodon*, and *Macrauchenia*, the *Drepanodon*, and the *Glyptodon*; from Australia remains of the *Thylacoleo* (that queer marsupial which Prof. Owen demonstrates to be a carnivore, and Prof. Flower essayed to make out to be only a great root-feeding Wombat), the *Diprotodon* (a gigantic kangaroo, which probably did not hop, like the modern kangaroo, but went on all-fours), the *Nototherium*, *Macropus*, and many others. The most important acquisition during the past year is that of the Van Breda collection from Haarlem. This well-known collection, commenced by Dr. Peter Camper, the celebrated Dutch anatomist, more than 100 years ago, has since been largely increased by his grandson, the late Prof. Van Breda, secretary for more than fifty years to the Royal Dutch Society in Haarlem, who inherited Camper's original collection.

The series of specimens is particulary rich in remains of the great Meuse lizard, the *Mosasaurus hofmani*, and of a giant tortoise, the *Chelone hofmani*, and many fine remains of fishes and reptilia from the Maestricht chalk,

the Solenhofen stone, the Brown Coal of Bonn, the Miocene limestone of Oeningen, and the Trias and Keuper of Germany.

Of English fossils the finest addition is that of the Wetherell collection, the author of which was for more than fifty years a diligent collector of London clay fossils at Highgate and its vicinity. This collection is a truly Metropolitan series, and will, when the new Museum is prepared, doubtless have, as it deserves, a suitable exhibition case. Altogether there have been added to the Department of Geology a total of 4,789 specimens.

Mineralogical science is well cared for by Prof. Maskelyne. Only 513 specimens have been added, but these are each one a valuable addition to the cases. Among the most important may be mentioned the Chlorides and Iodides of Silver, in distinct crystals, from Chili, and a series of remarkable crystals and masses of Iceland spar.

In the Laboratory new minerals of the Dufrenite class have been examined, to which the name "Andrewsite" has been given; a blue mineral from South Africa proves on analysis to be "Percylite," only known hitherto in the specimen preserved in the British Museum. The Cranbourne Meteorite is still being investigated.

In the Botanical Department, Mr. Carruthers reports a long series of important acquisitions during the past year. Among other interesting additions to the exhibited series may be named a series of microscopic preparations of fossil plants, selected partly from the collection bequeathed by Robert Brown, and partly from the specimens subsequently acquired by the trustees, and exhibited so as to show their minute structure by the help of light reflected from mirrors.

It will be seen that the key-note of the Report is the hope of better times coming, not only for the National Collection, but for its Officers, in the New Museum. In this hope we most heartily concur, and trust that not the least reform which will then be inaugurated will be the entire modification of the present system, by which the actual amount of instruction gained by the public appears to be in inverse proportion to the vast resources of this great establishment if well and ably administered. This is not as it should be. There is no reason why the British Museum should not become, under its new management, one of the first educational establishments of the country.

NEW WORKS ON GEOMETRY

Solid Geometry and Conic Sections, with Appendices on Transversals and Harmonic Division; for the Use of Schools. By J. M. Wilson, M.A. (Macmillan and Co. 1872.)

Geometrical Note-Book, containing Easy Problems in Geometrical Drawing preparatory to the Study of Geometry; for the Use of Schools. By F. E. Kitchener, M.A. 2nd edition, revised. (Macmillan and Co.)

THESE works are by mathematical masters at Rugby School. Their united aim (in connection with Mr. Wilson's two previous parts) is to provide a complete course of geometrical teaching, and so to meet a crying want of our schools, which has of late led to so much agitation. It is now nearly four years since Mr. Wilson's first part and Mr. Kitchener's first edition appeared, at which date an eminent reviewer, in his notice of the "Elementary Geometry," remarked that the forces were mustering for the battle. Since that time considerable progress has been made in the agitation, and, thanks to the Association for the Improvement of Geometrical Teaching, which owes its origin in part to a correspondence commenced in this journal, there seems to be a fair prospect, if not of perfect success, yet of the whole subject of geometrical teaching being placed on a more satisfactory basis.

The very first resolution put forward by this Association in its second Annual Report is, "That some practical familiarity with geometrical construction should precede theoretical study; and that the teaching of geometry would gain by the free introduction of easy exercises and numerical examples or illustrations." We presume that a main object of Mr. Kitchener's book is to meet this suggestion; and from the fact of a second edition being called for we may fairly suppose that it has met a felt want. It will be barely necessary to do more here than point out wherein this edition differs from its predecessor. Without going into details, we may state that the size of the page has been materially enlarged; that instead of blank spaces being left for figures to be drawn by pupils on the printed pages, there are now inserted between every two pages of type two sheets of admirable blank paper. The paging is continued on these blank sheets. There are three parts in the place of two; the use of the protractor is relegated to part ii.; on p. 37 a return has been made to Euclid's definition of parallels (this is doubtless in consequence of the agreement come to and embodied in the seventh resolution of the above cited Report); the third part contains a few simple constructions connected with tangency and the circumscription of figures. There are apparently no typographical errors in this well got-up work, and we take leave of it commending it to all teachers engaged in the arduous task of instilling geometrical notions into junior students' heads.

It appears to us that the following are the only oversights to point out:—Should not 7 precede 6 on p. 49? Exercise 30, p. 25, should be expunged; it is given on p. 61, 4, where a definition is given which is wanting in the former place. In Exercise 14, p. 62, the case of parallel lines has been overlooked; and on p. 50, for 514 we get 534 nearly =.

To turn now to Mr. Wilson's book. This is characterised by his usual clearness and ability. The selections and the grouping are, in the main, all that we desire in a school treatise; we would, however, have preferred a somewhat more extended treatment of the sphere and cylinder. Some properties of the former are cited on p. 79 which have not been given in the work itself. A little fuller notice of these solids would fit the book to meet the requirements of candidates for the B.A. London Examination; as by a recent extension of the University scheme students are expected to be acquainted with the proofs of the properties of these figures, which are assumed in treatises on mensuration of solids. As indicated in the title, the work consists of three parts; the first part covers the ground occupied by Euclid xi. 1—21, and further treats of polyhedra and stereometry, the whole presented in a clear and satisfactory manner, certainly in a form not hard to be

understood by an average schoolboy who has mastered any ordinary treatise on Plane Geometry. We have found our own pupils to read it with interest, partly for a reason put forward by the author, that "the geometrical imagination is exercised." We notice for the first time, we believe, in a text-book, the term "disposition," in the following connection :—"Parallel planes are those which have the same disposition in space:" the discussion raised in these columns in connection with Mr. Wilson's application for a suitable term will be within the recollection of most readers, and if we mistake not we are indebted to Dr. Hirst for the suggestion of this appropriate word. We note on this page (9) a curious oversight, which, however, the student can readily correct.* On p. 45, for $\frac{1}{2}\pi$ read 2π. In the short and handy notice of transversals we observe the use of the term "sense," as equivalent to direction. On p. 64, last line but one, read $\frac{DA}{CA} = -\frac{BD}{BC}$; and on p. 67, third line, read $\frac{AB.CD}{BC.AD} =$ &c. Other slight typographical mistakes will give the reader no trouble. The last of the three parts contains a capital summary of the chief properties of the conic sections—just sufficient, we think, for class use; for, with the limited time at our disposal now-a-days, it is almost useless attempting to take up such extended treatises as the admirable ones by Drew and Besant. The figure on p. 128 is not quite correctly lettered in accordance with the proof that accompanies it.

We have examined and used this book with much satisfaction, and hope to see it pass through several editions, as we think it calculated to raise the study of solid geometry "to a more prominent position in geometrical instruction," and to put the subject of geometrical conic sections in a more satisfactory state than it at present occupies.

R. T.

* There is a similar oversight in the proof of Cor. i., Theorem 27, p. 35.

OUR BOOK SHELF

The Year-Book of Facts in Science and Art. By John Timbs. (London: Lockwood and Co. 1872.)

MR. TIMBS's books always produce upon us the effect of an ill-assorted dinner. There is plenty of solid food, but along with it some that is anything but wholesome; and the concatenation is badly managed, and the cooking none of the best. To take the concatenation first: The paragraphs in this volume are arranged under a variety of headings, but on what principle the assortment is made we have failed to discover. Thus we have paragraphs on Surface Movements of the Earth and on the Secular Cooling and Figure of the Earth, under Natural Philosophy; on Earthquakes and Volcanoes, under Geology and Mineralogy; on Protuberances of the Sun, under Natural Philosophy; and on Vast Sun Spots, under Astronomy and Meteorology; while two long accounts of the Gun-Cotton Explosion at Stowmarket are given, one under Mechanical and Useful Arts; the other under Chemical Science. Next, as to the cooking, in other words, editing. Very little pains appear to have been taken to go to the best authorities on each subject, or to trace statements to their original source. For instance, admirable papers as are the *Spectator* and *Pall Mall Gazette*, we hardly care to know what the one thinks as to the chance of men ever being able to fly, or the other about the sensitiveness of frogs during vivisection; and some more authoritative judgment on Prof. Tyndall's experiments on the purity of water might have been found than that of an anonymous writer in the *Times*. It is surely the result of careless editing to find on the same page two descriptions of the same bone-cave in Pennsylvania, although in one instance it is described, by a slight geographical confusion, as being situated "in Philadelphia." Very familiar proper names are constantly misspelt or misquoted. Thus we hardly recognise Padre Secchi under the disguise of "Seeche;" or the admirable Genevan Society which has published so many valuable contributions to science, under the name of "The Society of Physics and Natural History of Ginevra." As to the unwholesome and absolutely indigestible food, we will refer only to a single actual error. Canon Kingsley will be surprised to be made responsible, on the authority of our excellent contemporary the *Builder*, for the statement that "lime is a metal called by chemists 'calcium;' but it is never found in that state in nature. It is found in a rocky or chalk form." Other blunders almost as gross could be quoted. The book gives us the impression that the compiler was under the necessity of filling a certain number of pages, and that for this purpose the scissors and paste were freely used on the material that came the readiest to hand. The worst is that by the non-scientific public such books are taken as an authoritative record of the progress of science during the year, and of the most important inventions and discoveries, and the most striking new applications of old principles.

Righthandedness. By Daniel Wilson, LL.D., Professor of History and English Literature in University College, Toronto. Pp. 40. (Toronto, 1872.)

THIS pamphlet contains some useful facts bearing on the question why some people are left-handed, and the antecedent question why more are right-handed. Prof. Wilson takes a sufficiently comprehensive view of the subject. He admits that the problem does not concern the hand alone, but the foot, the eye, and the whole body. He admits that a similar preference for one side may be found among the lower animals; and he re-states with some fresh illustrations the grounds which have led previous writers on the subject to conclude that right-handedness is the normal condition of all the existing tribes of man, and has been so as far back as history, tradition, or language extend. He raises the question whether, in some cases, we have not translated the ancient terms inversely, so that the favourite and stronger hand may have been with certain of the ancient nations the left; but has no difficulty in showing, from the described relations to the points of the compass, from the form of weapons, and from many other sources, that what we call the right hand has always been the one chiefly used. In another passage Dr. Wilson refutes the idea that the Egyptians were a left-handed race, and shows that it has arisen from the greater convenience of drawing the figure left handed in certain cases. The evidence from language is discussed, and the etymology of the words *dexter*, *decem*, *quinque*, *sinister* is accepted, as given by Grimm, Donaldson, and other philologists, who long ago pointed out the connection in various languages between the words which express the number ten and those for the right hand, the fingers of which complete the tale of ten.

The learned Canadian Professor does not offer any new theory of the reason for the general preference of the right hand, or the occasional preference of the left. He discusses the hypotheses advanced by Barclay, Hyrtl, Gratiolet, and Buchannan; and rightly rejects them all, as insufficient or contradicted by anatomical facts. Besides these writers, and Prof. Humphry, of Cambridge, who is also quoted, Dr. William Ogle has lately published, in the "Medico-Chirurgical Transactions," an interesting paper on "Dextral Pre-eminence," in which several new facts and observations are recorded.

Prof. Wilson's paper is a valuable contribution to the literature of the subject. It seems, however, to have been

hastily revised. Thus, in four lines quoted from Ovid, there are two bad misprints, besides a doubtful reading.

At present the results obtained in this inquiry are the accumulation of facts and the refutation of untenable explanations. One may also, perhaps, affirm (1) that the primitive condition of man and other vertebrates was, as their early fœtal condition still is, one of complete bilateral symmetry of structure, and also of functional symmetry; (2) that this primitive ambidextrous use of the limbs is occasionally superseded in animals, and constantly in all races of men of which we have any knowledge, by a preferential use of one side; and that this is a necessary step in development as soon as the more delicate operations performed by a single hand take the place of those of digging, climbing, &c., in which both take part. It is, in fact, a differentiation produced by the same causes which have led to the specialisation of the fore and hind limbs in frogs, birds, or kangaroos, compared with their uniformity of structure and function in fishes, crocodiles, and horses; (3) the prevalent choice of the right hand when differentiation was established, must have depended on some slight advantage, at present unascertained, by which dexterity at last suppressed *gaucherie;* (4) The occasional preference for the left hand, which is often partial and sometimes hereditary, does not depend on any "coarse" structional abnormality, but is an instance of atavism—of reversion to the primitive and universal ambidextrous, or to a subsequent and partial lefthanded condition. Ocean Currents

IF a free body on the earth's surface should be moved from a lower to a higher latitude without friction by a force in the direction of the meridian, it would acquire a certain amount of relative eastward velocity, which would be the same whether the body moved toward the pole with a very slow uniform velocity arising from a single impulse, or whether it moved with a continual accelerated velocity down a gradient by the force of gravity. If a particle of atmosphere or of the ocean is moved in the same way by a similar force, and does not acquire the same amount of relative eastward velocity, the difference between the velocities in the two cases is the true measure of the effect of friction. But from the amount of work done, or velocity generated or destroyed, nothing can be inferred with regard to the acting force, unless we take into account the length of time during which it acts. The velocity of the interchanging motion of the water between the equator and the pole, discovered by Dr. Carpenter, is extremely small, perhaps not as much as a mile per day, and less than tidal velocities in the open ocean. If a great amount of eastward velocity, therefore, is destroyed by friction in the case of a particle of the ocean in moving from a lower to a higher latitude, it is not because the friction is great, but because it acts during a very long time.

If the velocity in the direction of the meridian were one mile per day, the deflecting force, at the parallel of 45°, arising from the earth's rotation, would be about equal to the force of gravity along a regular gradient of 6ft. between the equator and the pole. Both the velocities north or south and east or west, and the amount of friction belonging to any given velocity, are unknown quantities. The force down the gradient of 6 ft. between the equator and the pole, which Mr. Croll allows to be the measure of the force due to the difference of temperature or density between the equator and the pole, would soon give the particles of water without friction the velocity of one mile per day, and the question now is, whether the force would then be sufficient to overcome the friction belonging to this small velocity; for the inertia of the water being once overcome, all that would be required of the force would be to overcome the friction.

The velocity of motion between the equator and the pole being probably of the same order only as tidal velocities, we may suppose the friction in the two cases to be somewhat of the same order. Now the friction in tidal velocities in the open sea, when not regarded as entirely insensible, has always been regarded as a quantity of a second order in comparison with the disturbing forces producing the tides, or at least as being much less. But the force producing the tides is about equal to the force of gravity along a gradient of two feet between the equator and the poles. If we therefore suppose the force necessary to overcome the friction of tidal velocities to be one-fourth of that producing the tides, then the force of gravity on a gradient of 6 in. between the equator and the poles, would be sufficient to overcome the friction belonging to the slow velocities of the motion discovered by Dr. Carpenter, if we suppose, as above, that the amount of friction in the two cases is of the same order. But this is only one-twelfth part of what Mr. Croll allows to be the available force for this purpose. According to the preceding view, therefore, the difficulty is not in finding a sufficient force for overcoming the friction of Dr. Carpenter's slow velocities, but in disposing of the abundance of force we have on hand for that purpose.

Washington, May 24 WM. FERREL

The Wanderings of the Esquimaux

I AM much obliged to Dr. Rae for his courteous letter upon a subject in which he is so deservedly an authority, while I am only a student. The question upon which he joins issue with me, namely, the southerly migration of the Esquimax, is one upon which I ought to bow to his authority; but there are some difficulties attending the solution he offers which deserve, I think, consideration. If the Greenland Esquimaux came from the north, as both of us are agreed, it is probable that the stock from which they sprung are the so-called Arctic Highlanders of Smith's Sound, about whom Mr. C. Markham has written both in the *Ethnological Journal* and the *Journal of the Geographical Society*. They are broadly distinguished from the Esquimaux of America by the use of stone igloos instead of snow huts, and by their ignorance of boats, either kayaks or omenaks. These Arctic Highlanders are a diminishing race. M'Clintock tells us "that they have become alarmed by the rapid diminution of their numbers through famine and disease" (Travels, 137). Along the shores of Smith's Sound are the ruins of many deserted huts, moss-grown, and of considerable antiquity. The skulls of musk oxen without their lower jaws, a proof that they had been killed by Esquimaux, are also found scattered along the same coast (id. 76). These facts show that the Esquimaux were formerly abundant in very high latitudes, where they have now become very few in number. What is true of Smith's Sound is also true of the great Archipelago of the Arctic circle known as the Parry Islands. These also are dotted with the moss-grown ruins of ancient and deserted huts, the remains of a once numerous race in an area now, I believe, entirely deserted by the Esquimaux. These two places are in the highest latitudes yet reached by navigators.

Dr. Rae would make these Northern Esquimaux to be wanderers from the American Continent; but, putting aside the difference of customs, which seem to show that the American Esquimaux are not the primitive stock of the race, but have been sophisticated by contact with the Indians, I may quote the following passage from Mr. Markham, who has studied the question with some care:—"The American Esquimaux never go from their own hunting range for any distance to the inhospitable north. Except in the case of the Pond's Bay natives who followed up the whalers for a specific reason, there is no instance of their having gone north, and it is unreasonable to suppose that they would do so" (*Journal of Ethnological Society*, 4, new series, 135).

When I quoted the traditions about the migration of the Esquimaux having been southerly, I had the passage especially in my mind where Sir John Franklin describes the Chippewyan legend about the discovery of copper, beginning with the words, "The Chippewyans suppose the Esquimaux originally inhabited some land to the northward, which is separated by the sea from this country; and that in the earliest ages of the world a party of these men came over and stole a woman from their tribe, whom they carried to this distant country, and kept in a state of slavery, &c." (Franklin's Narrative, 146).

Dr. Rae, on the contrary, thinks they came from the west. Now Mackenzie, who certainly knew the country well, says:—"The progress of the Esquimaux, who possess the sea-coast from the Atlantic through Hudson's Straits and Bay, round to Mackenzie River, and, I believe, further, is *known to be westward. They never quit the coast*" (Mackenzie's Travels, 406).

The Asiatic origin of the Esquimaux seems to me to be a very problematical solution of the difficulty. There are Esquimaux in Asia undoubtedly. The so-called Tchuktchi of Tchuktchi Ness are Esquimaux, but they are a very small fragment, and are apparently emigrants from the opposite shores of Behring Straits. Between them and the American Esquimaux there is a considerable intercourse, which has led to the products of Russian manufacture being found along the shores of the Arctic Ocean; and the American Esquimaux constantly pass the Straits for purposes of barter. Beyond the fragment of this people found at the extreme north-eastern part of Asia, and a few of the Kamskatkans, I know of no Asiatic race whose language, or custom, or physique, favours the opinion that they are connected with the Esquimaux. The course of migration has rather been westerly and easterly. The Tchuktchi proper and the Koriaks, who are a very different race from the Tchuktchi of Tchuktchi Ness, have been pressing to the west, and have uprooted numerous tribes, such as the Omoki, &c. These latter were portions of a widely-spread race now represented by the fast-diminishing Jukagiri, whose language, so far as I have examined it, is very different from the Esquimaux (a copious vocabulary may be seen in Billing's travels). Again, between the travels of Cooke and those of Whymper, the language of the inhabitants of Kotzebue Sound has changed considerably, and become more Esquimaux, which seems to show that the Esquimaux have quite recently been pressing in this direction also.

All these facts point to apparently only one conclusion, that the original home of the Esquimaux was in the regions near the Pole, from which they have migrated to a more temperate climate; and I can see no good cause for such migration, except the increasing rigour of the climate. The question is one of great interest, both to ethnology and physical geography, and I hope Dr. Rae will favour your readers with some more facts on the other side

While the evidence seems to be overpowering that the climate has been gradually growing more severe in the highest latitudes, there is a good deal of evidence which points to a corresponding decrease of severity elsewhere. We cannot read the descriptions of Gaul and Germany in Roman times and reconcile them to the state of things that at present exists there, without believing that the climate has very much improved. It is rash to take isolated seasons, but we may compare with profit the accounts of the terrible winters of Roman days, during which the Rhine and Danube were frequently frozen over, with the comparative mildness of modern times. The reindeer and the elk then ranged far to south of their present habitat. Ovid's lamentations over the fearful severity of his place of exile on the coast of Thrace are matched by the accounts of white foxes, &c., which then lived there, and by the proverbial rigour of the winters on the coasts of the Black Sea; while the diminution in the energy and vigour of the races that inhabit the Mediterranean borderland can best be accounted for by the theory which makes them to have in some measure succumbed to a more enervating climate. If this be true, we have a very remarkable fact hitherto ignored, so far as I know, by scientific men, namely, that it is possible that circumpolar climate may have been very temperate when the climate of more southern latitudes was very severe. This paradox, upon which I should very much like to have the opinion of some of your correspondents, is favoured by the following fact:—"It is a common remark of those who frequent the Polar seas, that they find always the least obstruction from ice when the preceding winter has been very severe in more southern latitudes. In the year 1766, though the frost had proved most intense through the rest of Europe, the whalers reached a high latitude; and not to multiply instances, the three last seasons (*i.e.* 1815, 16, and 17), which have been reckoned very open, have succeeded to winters notoriously cold and protracted," *Edinburgh Review*, 30, 34). We have only to extend the analogy of a season to a number of seasons, and we at once get a similar result to the one above named, *i.e.*, that an increase of severity of climate in low latitudes is balanced by a diminution of severity in high ones. I need hardly point the moral in the present letter of the value of such a result in speculations on the existence of the mammoth in Siberia and Northern Russia during the Glacial epoch, &c.

Derby House, Eccles, June 4 HENRY H. HOWORTH

Origin of Cyclones

IN NATURE of August 17, 1871, Mr. J. J. Murphy calls attention to a paper by Mr. Meldrum on the origin of storms in the Bay of Bengal, &c. This paper advocates the theory of their origin "in the meeting of the trade-winds in the northern and southern hemispheres, at some distance north or south of the equator."

Mr. Murphy says:—"Over the greater part of the Pacific cyclones do not appear to be found. The reason of this probably is that, in consequence of the temperature of the sea changing but little with the seasons, the two trade-winds over the Pacific meet each other nearly on the equator all the year round; though I do not know how far this is confirmed by observations on the winds of that ocean."

Very little is known about the meteorology of this part of the Pacific, and my object in writing is to communicate to Mr. Murphy and others who may be interested in the subject the following facts:—

1. There is rarely a year without at least one cyclone passing through, or in the neighbourhood of, one of the following groups of islands, viz., Fiji, Samoa, or Hervey.

2. The cyclone season extends over a greater part of the period during which the sun is south of the equator; consequently, when the trade-winds from the north reach farthest south. Cyclones are most prevalent about the middle of the season, or rather later than the middle. They rarely visit us earlier than December or January.

3. They are usually preceded for a few days by strong northerly winds. During such winds we watch the barometer very carefully, as a sudden fall is a sure indication of a cyclone near at hand.

I may add that a strong northerly wind is blowing in this group at the present time. It was indicated by the barometer thirty-six hours before it reached us, and was preceded by a day's calm. It then burst upon us suddenly with fury, but after a few hours moderated to about the force of the S E. trade-wind.

S. J. WHITMEE

Leulumoega, Samoa, South Pacific, Jan. 8

P.S.—Since the date of my last note we have had two earthquakes—Nov. 13, at 5.5 P.M., vertical, with a great rumbling preceding and accompanying it; Dec. 15, at 12 noon: double shock, with an interval of thirty seconds: slight.

Rain after Fire

SOME old settlers believe that great bush fires cause rain. During this summer exceptionally dry weather has prevailed over the greater part of New Zealand, more especially along the eastern coast; in several of the towns prayers for rain have been offered up in the churches. I beg to send some notes of recent date extracted from our home diary. It should be stated that this district, adjoining Banks' Peninsula, has been suffering from extensive bush fires since the 18th of last month.

"Feb. 1. Strong N.-Wester; very hot; 92° in the shade under the back verandah. Heavy bush fire on the hill still burning; showers in the evening."

On the coast here it is very unusual to have rain with a N.W. wind, which is dry and parching.

"Feb. 3. Strong N.-Easter; showers in the evening."

The bush fire was still burning, and continued to do so till the 7th. On the 5th most of the neighbours turned out to save some property in great danger of being destroyed by the fire. N.E. is a cool dry wind from the sea.

"Feb. 16. Strong N.E. Heavy bush fire under Omauhate and about Cass Peak. Slight showers from the S.W. in the morning; wind veered round to N.E."

Our rainy quarter is S.W. with a low temperature; less frequently we experience thick weather from S.E., accompanied by fine rain. These fires have been traversing a range of hills (more or less timbered in the gullies), their heights from eleven to about four hundred feet above the level of the sea. I believe the showers noted to have been as local as the fires; the direction of the wind is given as prevalent on the dates mentioned, with some indication as to its strength, but we have no memoranda as to its force during the actual fall of rain. Opportunities of watching the gradual formation of cumulus cloud above dense volumes of smoke are by no means rare in this part of New Zealand, where the occupiers of Crown land have periodical burnings of their run, or great portions thereof, in early spring. These notes are forwarded in the hope of helping to illustrate the question of whether fires cause rain, no opinion is ventured on the subject, but this curious phenomenon should be further investigated. THOMAS H. POTTS

Ohinitahi, New Zealand, Feb. 19]

On Adhesion Figures

A DROP of crude carbolic acid placed on the surface of cold water exhibits the most surprising and beautiful "cohesion figures." I am not aware that Mr. Tomlinson has described the behaviour of this substance. So lively and unpredicted are the movements of the drop that its action resembles that of a living creature. At first it pulsates, then its edge breaks up into crispations, and a motion begins like the waving tentacles of a sea-anemone. Sometimes the drop will sail about in a crescent shape, or shoot out independent little rings, which gyrate and rush about like a rotifer, until at last they burst into a myriad of intensely active little specks. Warm water destroys all action, by lessening, I suppose, the adhesion of the liquids.

To your readers it is trite and useless to remark upon the interest that attaches to the careful and continued observation of the most familiar things. But I wish the leisure classes could understand this. How many pleasant and instructive hours might some of them spend in examining such common things as essential oil dropped on water, even drops of ink falling through water, or puffs of smoke through air or a candle flame, or a hydrogen flame, or iron filings sprinkled on paper over a magnet, or, among other simple things, best of all a block of ice in a sunbeam. From the contemplation of such phenomena one rises with an increasing joy, and not a little humbled at one's own ignorance before the orderly mystery that pervades everything.

24, Elgin Road, W. J. H. SPALDING

A Suggestion to Opticians

THERE is a method of mounting self-registering meteorological thermometers very commonly employed, and one which for some purposes, as, for instance, for determining the temperature immediately over the surface of the ground, is an excellent plan.

I allude to the placing of the divided thermometer stem in a larger tube forming a jacket to it, and fixing it with india-rubber packing, which makes an air-tight stopper round the neck.

Now it is frequently observed that when thermometers fitted in this manner are exposed to cold, a copious deposition of dew takes place, both on the stem and in the interior of the jacket, rendering the accurate reading of the instrument a matter of some difficulty. I would therefore suggest to makers of this class of instrument whether it would not be advisable for them to *dry*, I do not mean merely heat, the air in the tubes, or else enclose some water-absorbing substance, as calcium-chloride, in the tube before finally inserting the india-rubber stopper.

It is extremely probable my suggestion is not a new one. I have no recollection, however, of having heard of such a plan being employed by any maker. G. MATHUS WHIPPLE

Kew Observatory, June 10

The Ferrara Floods

MAY I ask for space to draw the attention of engineers to the question whether the beds of embanked rivers rise or not? The affirmative is argued (and in reference to Ferrara) in the last chapter of "Rain and Rivers," against the negative of the eminent American engineer Ellet. The title of the chapter is "Ellet on the Mississippi." GEORGE GREENWOOD

Brookwood Park, Alresford, June 8

FORCE AND ENERGY

THE CONSERVATION OF ENERGY A FACT, NOT A HERESY OF SCIENCE

IN an article entitled "The Heresies of Science," published in a recent number of the *London Quarterly Review*, two widely different principles are oddly linked together as heretical dogmas, the doctrine of Evolution, and the Conservation of Energy.

On the doctrine of *Evolution* the writer has nothing to say.

Before discussing with the "Reviewer" the validity of the *Conservation of Energy*, it is quite necessary to define the terms which may be employed, such as Force, Energy, Potential, Sound, Light, Heat.

It is much to be regretted that a far greater degree of logical accuracy in the use of terms than is usually met with, does not exist amongst even the ablest writers on physics, for many of the arguments adduced against physical principles lie not against the principles themselves, but against the indefinite language in which they have from time to time been expressed. There is probably no term employed in physics that has been more misapplied, and in its misuse has led to greater confusion of ideas, than "force."

Force has been thus defined by our ablest modern physicist.* "What I mean by the word force is the source or sources of all possible actions of the particles or materials of the universe."

This definition of force is substantially the same as the writer's definition † to which the reviewer takes exception, but which may perhaps with advantage be thus amplified: Force is a mutual action between the atoms or molecules of matter, by which they are either attracted towards, or repelled from, each other; and by this action energy is imparted to the matter put in motion. It may be further remarked that force is essentially either attractive or repulsive.

The writer sees no reason to amend his definition of "Energy"—namely, that it is *the power of doing work*. It may, however, be remarked that the existence of energy in matter implies the existence of motion, and *vice versâ*; but it by no means follows that motion and energy are convertible terms, for motion means only the act of moving, or changing the position occupied in space.

The term "Potential" applied to force or energy means inactive, but capable of being called into action. Thus, if a weight be raised, a certain amount of energy is expended in raising it, and so long as the body is supported the energy expended in raising it remains potential in it, but when allowed to fall freely *in vacuo* to the level from which it was raised, the body acquires exactly the amount of energy that was expended in raising it. In the same manner the repulsive force of the molecules of the highly ignited gases into which gunpowder is resolved by ignition may with equal propriety be said to be potential in the unignited powder.

The remarks with which the writer's interpretation of the terms "force" and "energy" have been met by the reviewer may here be appropriately noticed. Quoting the introductory chapter already referred to, he adds: "his doctrine regarding the nature of force has thus no connection with sound philosophy; by force Mr. Brooke evidently means what other advocates of conservation mean by potential energy." Does then sound philosophy consist in the impossible task of agreeing as to the meaning of terms with those who do not agree amongst themselves? Or is sound philosophy monopolised by, and crystallised in the opinions of the reviewer? Sound philosophy would seem to consist rather in assigning appropriate meanings, involving no inconsistency or contradiction, to terms of frequent occurrence in all works on physics.

If the above definitions of force and energy be accepted, it is obvious that the term "force," as used by Grove, Tyndall, and many others, means sometimes force and sometimes energy. Thus, for example, "the conservation of force" becomes a simple truism, for its exercise being a function of matter, force must necessarily be coeval with matter. The reviewer (p. 22) thus quaintly expresses the relations of force, energy, and motion:—"A given motion viewed as a cause is force, while the very same motion thought as an effect is energy." Motion, it is presumed, can mean nothing else than the act of moving; but how the act of moving, whichever way we look at or

* Faraday, MSS. Croonian Lectures on Matter and Force, by H. Bence Jones, M.D. p. 35.

† Introductory chapter to the Sixth Edition of "The Elements of Natural Philosophy."

think of it, can either produce energy or do work, it is difficult to conceive; has this "any connection with sound philosophy"? and does not the reviewer here himself "forget that each thing is itself, and not something else" (p. 22, l. 89).

The writer would commend to the serious attention of his brother-physicists the above definitions; he would also submit the following definitions of sound, light, and heat, the former of which has, however, been elsewhere declared to be incapable of definition,* as well as by the reviewer (p. 22). Sound may be defined to be the impression produced by certain vibratory movements of matter upon appropriate sensuous organs, including both the receptive and perceptive apparatus. Whether the tympanum be incapable of receiving sonorous vibrations, or whether it vibrate sympathetically while the structures of the internal ear are incapable of appreciating its vibrations, there can be no sound.

And why may not the same definition apply to light and heat? It is, in fact, far from improbable that the perceptions of light and heat may result from the impressions produced by the same identical vibrations on different receptive organs; that of light on the eye and its nervous appendages, that of heat on the organs of common sensation. In common parlance, the terms sound, light, heat, will doubtless continue to be applied indiscriminately to the vibratory motion producing, and to the impressions produced; and to this there can be no objection, provided no advantage be taken of the misnomer to found thereon an assumption of the identity of the proximate cause and the resulting effect.

The reviewer has sought to kill two birds with one stone, and has made a vigorous onslaught against the conservation of energy in general, and the writer in particular, regarding the theory of latent heat; but it may reasonably be questioned how far "sound philosophy" is shown in attempting to convict an author of admitting an insuperable difficulty in the adoption of a given principle by quoting his statement of the difficulty, and coolly suppressing his immediately subsequent explanation of it. He thus quotes the writer†:—"Latent heat has ever been held up as the great stumbling-block of the dynamic theory, because it is impossible to conceive motion to be reduced to a state of quiescence, but remaining still ready to start again into action."

But instead of continuing the quotation thus:—"This, however, is merely a confusion of ideas, the fact being that when any substance passes from the solid to the liquid, or from the liquid to the gaseous form, a certain portion of the impressed heat-force is continuously occupied in overcoming molecular attraction, and thereby effecting the change of form; and this heat cannot be imparted to other bodies so long as it is occupied in maintaining that change," he ventures to state:—"In this we quite agree, and hence we think it unnecessary to give Mr. Brooke's reasons for believing a doctrine which he allows to be inconceivable"!!! Whether "sound philosophy" or not, is this common literary honesty? What Mr. Brooke allows to be inconceivable is obviously not the doctrine itself, but the conclusion drawn from fallacious arguments adduced in opposition to it; for to assign reasons for believing what one allows to be inconceivable would be nothing less than pure and simple evidence of mental alienation.

The fact is that the term "latent heat" is an unfortunate one, and has mystified the reviewer, as well as many others. It ought long ago to have been consigned to the limbo of discarded hypotheses, together with the material or corpuscular theory of heat from which it arose. If heat consisted of material particles, it might be supposed to become latent among the molecules of grosser matter, just as a handful of shot, if dropped into a box full of marbles, would lie hid amongst them, and be lost to sense, and would so remain until shaken out again; but mere vibratory motion cannot be theoretically dealt with in this fashion.

A much better term would be *engaged* or *occupied* heat, for the so-called latent heat is wholly engaged or occupied in maintaining the change—first from the solid to the fluid state, and secondly from the fluid to the gaseous. The facts are very plain; a pound of water at the temperature of 0° C., or the freezing point, mixed with a pound of water at 79° yields two pounds at the mean temperature of 39·5°; but a pound of ice or dry snow at the temperature of 0° mixed a pound of water at 79° yields two pounds of water at 0°, because the 79° of sensible heat in the water are now employed or occupied in maintaining such an amount of vibratory motion in the molecules of the ice, that they are no longer able to obey that polar attraction by which they were previously aggregated together in given directions so as to form crystals (for though not so evident in ice, the crystalline character of snow is notorious), and the heat-energy, being thus occupied in doing work, is incapable of doing any other work, as for example on the organs of sensation, at the same time; on the principle that you cannot "eat your cake, and have it too." The same reasoning applies to the change from the fluid to the gaseous state; but in this case a much larger amount of thermic energy is employed in so far removing the molecules from the sphere of each other's attractions that the balance of their mutual forces is repulsive, and so long as that repulsion is maintained, the dry steam manifests all the properties common to the fixed gases. "Latent" heat, then, when properly understood, ceases to be a "stumbling-block to the dynamic theory of heat."

One finds oneself occasionally brought by circumstances into an unwelcome generalisation. Thus the reviewer, speaking of the supporters of "conservation" in the lump, says (p. 21) "they take it for granted that force is motion and nothing but motion." This the writer entirely and absolutely denies. The reviewer, then immediately preceding his observations on the writer's views, quotes from Prof. Bain that "Inert matter in motion is force under every manifestation." This is plainly an abuse of language, in which the writer, as one of the "they," declines to participate; inertness and force are hardly concomitant ideas, and matter, whether in motion or at rest, is assuredly not force. The term heat-potential adopted by Mr. Rankine is admissible only in relation to heat as previously defined; the thermic energy can hardly be termed potential while it is employed in doing work.

The reviewer (p. 19) quotes, and objects to, the explanation of latent heat offered by Prof. Tait: that while sensible heat is *motion*, latent heat is *position*. The writer must acknowledge his inability to derive any definite idea from this statement of Prof. Tait; he cannot therefore express either assent or dissent.

The writer must plead guilty to having made use in the treatise above referred to, in common with many others, of a phrase which is not strictly accurate, viz., that sound, light, heat, and electricity are modes of motion. It would be more exact to state that they are so many forms of energy, or effects due to matter affected by certain modes of motion.

It is rather surprising that the reviewer should have ventured to dogmatise on the very slender knowledge either of physical facts or hypotheses that he evidently possesses. Thus he states (p. 33, note) regarding the investigations of Dr. Joule:—

"By means of machinery a weight of 772 lbs. is made to turn a small paddle-wheel placed in one pound of water. Dr. Joule found that the descent of the weight with a given velocity through one foot raised the temperature of the water exactly 1° F." Now this small sentence contains

* "A logical definition of sound is impossible." Dr. M'Cann on "Force and its Manifestations," a paper lately read before the Victoria Institute.

† Elements of Natural Philosophy (p. 786).

a curious concatenation of errors. Dr. Joule never employed a weight of 772 lbs., for the weights he employed were all under 30 lbs.; he never employed the energy acquired by his descending weights in stirring an exact pound of water, for the stirring vessel was not constructed to hold that particular quantity; neither did he find that the descent of the weight with a given velocity raised the water exactly 1° F., for the velocity of descent has nothing whatever to do with the result; since precisely the same amount of energy is acquired by a body in descending through the space of one foot by the action of gravitation, whether one minute or one month were occupied in the descent. For the sake of convenience, and in order to avoid a source of error, it was desirable only that the weights should descend slowly, and with a tolerably uniform velocity.

So much for the reviewer's knowledge of facts; now as to his knowledge of theories. He writes (p. 31):—

"The supporters of the doctrine of the indestructibility (? conservation) of energy have adopted a method the reverse of scientific. They start with the assumption of perpetual motion by means of transformation. In order to make facts fit their hypothesis, they take for granted that heat, light, electricity, and magnetism, are modes of motion, but not requiring a material basis to account for their phenomena. Some, however, seem to be aware that motion of necessity implies something moving, and that this something must be matter in some of its forms, and that consequently it is a great mistake to suppose that the dynamical theory is inconsistent with the materiality of heat. Finding that they have been a little too hasty in getting rid of the old imponderables, they are now quietly bringing them back under a new name, hoping, doubtless, that their few remaining friends may not be able to recognise them. Instead of the 'imponderables' we now have the 'luminiferous ether' which fills stellar space, and even permeates all the grosser forms of material existence."

This sentence expresses a gross misrepresentation of the course of philosophic thought. Can the reviewer point out a single physicist who for a moment doubts that "motion of necessity implies something moving, and that this something must be matter in some of its forms;" it is an axiom that not "some" but all must obviously admit. When it was supposed that light and heat consisted of material particles projected with immense velocity from their radiant sources, and that electricity and magnetism were "fluids" travelling with similar velocity, it might be assumed that inter-stellar space is an absolute vacuum; but when the progress of physical knowledge developed phenomena which were partially or wholly incapable of explanation on this hypothesis (such as diffraction and interference, and subsequently those of the polarisation of light and heat); but which became perfectly intelligble on the hypothesis that these forms of energy consisted in vibratory molecular motion transmitted with the same great velocity, the existence of a highly attentuated and elastic medium as the denizen of infinite space, became a necessary part of the theory; and this, in unavoidable ignorance of its precise nature, was termed "ether." Hence, in direct opposition to the reviewer's statement, physicists take for granted that "light, heat, electricity, and magnetism" do require a "material basis" (that is, matter as a means of their transmission) "to account for their phenomena;" and his dictum about physicists getting rid of the old imponderables, and now bringing them back again, is unmitigated nonsense.

The attribute of imponderability has been ascribed to the hypothetical substance "ether" by many physicists who hold that it monopolises the property of transmitting the waves of light and heat, and is therefore interstitially deposited in all kinds of matter. The writer is, however, more inclined to believe, with Mr. Justice Grove, that all kinds of matter are susceptible of these vibratory motions, and hence that the hypothesis of *interstitial* ether is gratuitous; his reasons for such opinion being elsewhere in print, need not be here repeated.*

It may be further suggested that for all that is positively known to the contrary, all kinds of matter may possibly be susceptible of a fourth state or condition, which may be termed the "ethereal," and which in tenuity and elasticity may be as far beyond the gaseous, as the gaseous is beyond the fluid state; possessing also the mechanical properties of a jelly, rather than those of a gas.

The writer can hardly be expected to take up the cudgels for others against the reviewer; but in concluding the remarks on this point, it may be observed regarding the reviewer's emphatic denunciation of an alleged descrepancy between Grove and Tyndall, that the discrepancy exists only in his own misunderstanding the quotation from the "Correlation of Physical Forces," viz., that "it requires no great stretch of imagination to conceive light and electricity as motions, and not as things moving," in which the writer clearly contrasts the undulatory and corpuscular theories, as commonly understood. Enough has now been advanced to show that the reviewer need not look very far from home for a conspicuous example of that which he has so freely attributed to the unhappy physicists, namely that they do but "darken counsel by words without knowledge" (p. 23).

The equivalence of dynamic and thermic energy is the only one that has as yet been determined quantitatively. He must be a bold man who denies that the sun shines at noonday; and scarcely less audacious is the assertion of the reviewer that the experiments of Dr. Joule do not confirm this equivalence. Dr. Joule conducted four distinct series of experiments, three series on the amount of thermic energy produced by molecular friction in stirring respectively water, oil, and mercury; the fourth, on that produced by the friction of two iron surfaces against each other. The four numerical results accorded very nearly, and after assigning to each result its weight, according to its estimated liability to error, he deduced the mean value of 772 foot-pounds as the dynamic equivalent of thermic energy.† In the metrical system, in which the units of quantity are one kilogramme, one metre, and one degree in the centigrade scale, the above equivalent is represented by 424 dynamic units, which, for brevity's sake, we may as well agree with the French in calling "dynams."

The reviewer, in ignorance probably of the amount of labour bestowed on this subject, seems to imagine that by ignoring Dr. Joule's results, he has demolished the basis of thermodynamics; but if so, he is grievously mistaken. It is a remarkable and unprecedented confirmation of this theory, that the numerical results arrived at by three distinct methods of investigation, in the hands of as many independent physicists, should be found to agree within very narrow limits of error.

It has been found by experiment that a less amount of heat is required to raise a gas maintained at a constant *volume* one degree of temperature, than when the gas is allowed to expand under a constant *pressure*. Suppose, for example, that the gas be enclosed in a vertical cylinder under a piston of 100 square inches area, the atmospheric pressure on this piston will be 1,500 lbs., and the raising this piston is equivalent to raising a weight of that amount. Dr. J. R. Mayer, assuming that the difference in the quantities of heat in the two cases above mentioned is equivalent to the work done by the expanding gas, proceeds to determine the numerical value of these equivalent quanti-

* Lecture on Force and Energy, delivered at the Royal Institution, *Medical Times and Gazette*, July 8, 1871.

† For the sake of those readers who are not already familiar with this subject, we may state that a foot-pound is the amount of energy acquired by a weight of one pound in descending through the vertical space of one foot, or, in other words, the amount necessary to raise one pound one foot: and the numerical equivalent here given means that 772 dynamic units are equivalent to the amount of thermic energy required to raise the temperature of one pound of pure water, at or about the mean temperature of the air, one degree of Fahrenheit's scale.

ties. Taking the specific heat of air to be 0·267, as at that time determined by the observations of De la Roche and Berard, he found the dynamic equivalent of an unit of thermic energy to be 367 dynams. But if, in the calculation of this number, the more careful and accurate subsequent determination of the specific heat of air by Regnault be substituted, namely, 0·2375, the result gives as the equivalent 426 dynams; a result almost identical with that of Dr. Joule, but based on purely theoretical considerations.

Subsequently M. G. A. Hirn* pursued a course of observations exactly the reverse of that of Dr. Joule, namely, to determine the amount of heat converted into work in the steam-engine. Taking it as an axiom, which he showed to be in strict accordance with analytical investigations, that the difference between the heat existing in the steam as it enters the cylinder and that remaining in it after its exit, must be the thermic equivalent of the work done in and by the engine (which difference in the best constructed engines amounts to about 5 per cent. of the total heat due to the combustion of the fuel), he determined the value of one thermic unit to be 425 dynams; a remarkable result, and intermediate between those previously obtained by Mayer and Joule. In the face of such overwhelming concurrent evidence will even the reviewer be still bold enough to assert that the conservation of energy is a myth?

The principle of the dissipation of energy, as a corollary to that of its conservation, is of course equally ignored by the reviewer; but as his remarks on that point have no relation to anything beyond his own inner consciousness, it must here suffice to give a familiar illustration both of the conservation and the dissipation of energy, in the action of the rifle-ball. This reaches the target with less velocity, and consequently with less energy, that it possessed on leaving the muzzle; a portion of its energy has been expended in producing heat by friction against the particles of air between which it passes, which is dispersed through the surrounding atmosphere, and thus becomes *dissipated*. On reaching the target the progressive motion of the mass is arrested, and converted into molecular motion, which is cognisable only as heat, by which the mass is reduced to the fluid state, and splashes of molten metal are scattered in all directions. These again impart their heat partly to the air through which they pass, partly by radiation into space, and partly to the ground on which they fall; and thus the whole energy of the ball becomes dissipated. An analogous explanation will apply to all other cases of the dissipation of energy; thus the principle may be indefinitely illustrated, but it is hoped that it has now been sufficiently established that the conservation of energy is a fact, not a "heresy of science," the reviewer's opinions to the contrary notwithstanding, for

> A man convinced against his will
> Is of the same opinion still.

Want of space forbids the consideration of the larger cosmical relations of the conservation of energy to both organic and inorganic existence; one proposition only shall be alluded to as having been by some writers rather overstrained, viz., that the amount of energy in the world is unchangeable, the sum of the actual or kinetic and potential energies being a constant quantity. This may be taken as a postulate, and is probably true, but it is a proposition that is equally incapable of proof or of disproof, because the amount of potential energy in a body can be determined only by its development into actual energy, and cannot therefore be predicated. For example, two stones of equal weight lie one at the bottom of a well, the other on the ground at its edge; both are raised and placed side by side on the top of the windlass frame, much more work has been done on one than on the other, but can any one predicate in which of the two the greater amount of potential energy resides? Or is there any conceivable difference in the amount of energy acquired by either, otherwise than as dependent on its descending through the greater or the lesser distance?

It may, in conclusion, be remarked with much regret that the principle of the conservation of energy has by some been misapplied in a fruitless endeavour to supersede the necessity of a creative intelligence. To the mind of the writer, and, it is earnestly hoped, to that of most of his readers, the indisputable establishment of this principle conveys only a more exalted idea of that infinite wisdom by which the perpetually recurring transformations and interchanges, not only of the materials, but also of the powers, of Nature are rendered subservient to predetermined laws, which govern the comfort and welfare of all created beings.

CHARLES BROOKE

* Cosmos, v. 22, 1863.

SPECTROSCOPIC NOTES*

ALTHOUGH P. Secchi and others have recently published descriptions of the different varieties of solar prominences which have been observed, well illustrating the many forms in which these outbursts from the sun's chromosphere occur, a careful record of such disturbances as may be out of the more common order may in the end assist us to a further knowledge on this subject.

While looking for bright lines near F in the spectrum of a low prominence situated 25° north of east, at 11.35 A.M. (April 2), my attention was called to what appeared to me a sudden displacement of the F line toward the violet end of the spectrum.

I immediately brought the C line into the field of view, in order to discover if any change was taking place in the form of the prominence, but was wholly unprepared for the spectacle which met my eye. Upon widening the slit I found that where only twenty minutes before there had been a comparatively low mass of prominence matter not exceeding 50″ in height, and remarkable only for the brightness of a jet issuing from the southern portion which was but slightly raised above the chromosphere, there had been an eruption of matter on a grand scale.

Fig. 1 represents the prominence as first seen at 11.15 A.M. At 11.35 A.M. the northern portion had entirely disappeared, and from the low mound, at the point where the jet mentioned above had been seen, an eruption had taken place far exceeding anything I have ever witnessed. Far above the chromosphere the air was filled with long wisps of glowing hydrogen, ranging from 20″ to 50″ in length, with the appearance of having been ejected in quick succession. Above them floated detached masses, in the form of thin fleecy clouds, and the highest point reached by these was fully five minutes of arc, or about 135,000 miles above the sun. In the mound appeared a low, sharp horn, exceeding in brightness any other portion of the prominence. The grandeur of the eruption lasted but a few minutes, gradually fading in brightness and diminishing in size.

Fig. 2 gives a correct idea of the general form and extent of the prominence as seen at 12 M.

When next observed at 1.40 P.M., nothing was left but a small cloud mass of about the height of the prominence when first seen, at 11.15 A.M. To the north of this, however, were two very small horns, of great brightness. It has generally been noticed that the appearance of these bright points in the chromosphere is a forerunner of increased activity. The forces at work beneath were only gathering strength for a final outburst, which, if not so great in extent, proved to be equally magnificent. I had not long to wait; for after a few minutes spent in examining the F line, just as the clock was striking the hour, I again brought C into the field, and found myself only in

* Reprinted from advance sheets of the Journal of the Franklin Institute furnished by the Editor.

season for the grand *finale*. The chromosphere had again belched forth, and far above the sun could be seen the ejected matter, reaching to the height of 94,500 miles. The *débris* was in the form of jets or wisps, which appeared to be falling toward the chromosphere, here and there fretted with sharp horns or bristles. The remains of the first eruption existed unchanged since last seen, at

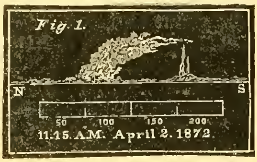

Fig. 1. 11.15. A.M. April 2. 1872.

1.40 P.M., but the changes in the form of the new one were rapid; at one point the filaments were so interlaced as to resemble close network. In the more elevated portions the jets soon lost their brilliancy, and in less than

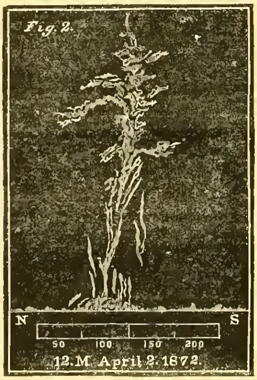

Fig. 2. 12. M. April 2. 1872.

an hour scarcely anything remained but a few stray wisps floating low down near the chromosphere.

Fig. 5 exhibits the change which the last outburst had undergone at 2.20 P.M.

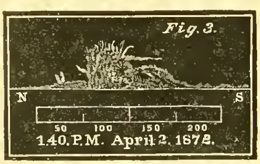

Fig. 3. 1.40. P.M. April 2. 1872.

During the phenomena the C and F lines were completely broken up, being displaced toward both the red and violet ends of the spectrum, the greatest displacement being toward the violet, in the F line extending to the iron line above F numbered 2082 in Kirchhoff's map. The D_3 line also suffered a sensible displacement. I examined the magnetic needle during the outbursts and an hour afterwards, but could detect no unusual disturbance. In the evening there was a slight auroral display.

Fig. 4. 2 P.M. April 2. 1872.

The portion of the chromosphere in which the eruptions took place was in the neighbourhood of a group of spots which were just making their appearance upon the eastern

Fig. 5. 2.20 P.M. April 2. 1872.

limb of the sun. The spots were completely surrounded by faculæ which radiated from the spots themselves, and could be traced to the sun's edge. Fig. 6 shows the position of the spots upon the sun at the time of the eruptions. The sketches were made at the time of observation, and are as correct as the duration of the phenomena would allow, the general form and most of the details being preserved.

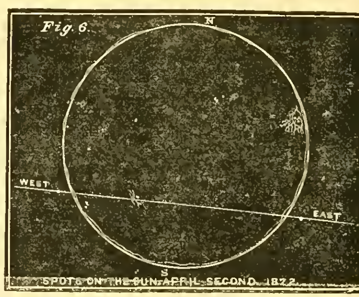

Fig. 6. SPOTS ON THE SUN, APRIL SECOND, 1872.

JOHN H. LEACH

ANCIENT AND RECENT STONE MONUMENTS

IN Mr. Fergusson's new book on Ancient Stone Monuments, mention is made of the Menhirs and Dolmens, both ancient and modern, which are found in the Khasia Hills, North-Eastern Bengal.

Having been for some time engaged in the survey of these hills, I can furnish a few particulars concerning these monuments which may be of interest. On one occasion, returning to my camp after a day's work, I was startled by hearing a loud shouting as of a number of men exerting their strength together and getting the time by shouting in chorus, much as sailors do on board ship.

I found that the sound proceeded from an assembly of Khasias, who were putting up three of these menhirs to the memory of a deceased villager. They were at a considerable distance from me, so that I could not clearly see their mode of procedure, and as on occasions of funerals and the ceremonies connected with them the Khasias are invariably more or less drunk and unruly, it would have been inexpedient to have gone amongst them. I was therefore compelled to wait until the next morning, when I went and inspected the scene of operations.

I found that three menhirs of no very great size had been put up, and that the stones had been raised in a very simple way by the use of long levers formed of young trees and ropes made of an exceedingly tough kind of creeper found in abundance all over these hills. The whole affair had been made the occasion of a feast on a very large scale; bones of slaughtered cattle, and empty grog jars lay around in numbers; the skulls of the oxen (some fourteen or fifteen in number) being arranged in a very fantastic way before the menhirs. As the arrangement of these skulls at once suggested to my mind the probable origin of a well-known architectural ornamentation, I attach a sketch showing how they were placed, viz.,

in a row at even distances apart on two horizontal poles, which were themselves supported on two upright poles. I was at some pains to inquire the meaning of these menhirs, but could only gather that they were intended to perpetuate the memory of some local celebrity.

In the case of the dolmens, so often found put up in front of the menhirs, I was informed that they served to give a kind of rough shelter to the ashes of the deceased, these ashes being kept for a year or two in the house and then brought out and scattered under the broad flat stone of the dolmen.

Moreover, the Khasias use these dolmens in their extraordinary form of divination by the breaking of eggs. This divination, which may be said to form their nearest approach to a religious worship, and which is on that account of peculiar interest, is conducted as follows:—On the top of the dolmen the Khasia who officiates puts five little pellets of clay and chewed betel nut, in the form of a semicircle, thus—

o

o

o

o

o

Then he stands upon the stone, and commences a wild kind of chant, having a rhythm and intonation utterly different from that of their ordinary songs. At a certain period in this chant he draws an egg from his pouch, and dashes it down on to the stone, as near the centre of the semicircle as he can. If the mass of the yolk scatters towards and over the pellets the omens are propitious, each pellet of the five having its meaning; but if the yolk scatters away from the semicircle of pellets the prognostication is unfavourable.

In his book Mr. Fergusson seems to suppose that the Menhirs and Dolmens mark places of assembly; but this is not the case, for near almost every large and old-established village there is found a place of assembly provided with stone seats, often prepared with much labour, and well adapted to the purpose for which it is intended.

I would also demur to Mr. Fergusson's inference that the Khasias are a physically inferior race; on the contrary they are a race possessing muscular strength to a singular and exceptional degree, as witness the fact that it is a very ordinary feat with them for one Coolie to carry a full-grown man in a kind of chair strapped on his back, along a road more than eight miles long, and ascending upwards of 4,000 feet.

M. T. SALE

DISCOVERY OF EXTINCT MAMMALS IN THE VICTORIA CAVES, SETTLE

THE scientific public will be pleased to hear that the Committee who have been exploring the Settle caves for two or three years past, have at length met with a great success. Till within the last fortnight we had discovered only remains of different ages from the Neolithic period to the present. These, though of great interest as throwing light on the vicissitudes and succession of later races, had to a certain extent been forestalled by the previous researches in this district of Mr. James Farrer, of Ingleborough, and by Mr. Jackson, the original discoverer of the Victoria Cave, and present superintendent of the work carried on in it by the Committee. Those remains were all in comparatively recent deposits. Beneath them was a great thickness of barren ground, consisting of a laminated clay in some places twelve feet thick, and below that again a great accumulation of angular fragments of limestone in a matrix of clay.

At a depth of about twenty feet in this we have now found elephant, rhinoceros, hyæna, a crushed canine of a much larger carnivore, &c. The elephant's teeth found belong to a young individual, and the number of gnawed bones and other indications of the cave having been a den of some large carnivores render it probable that the elephant was dragged into it by them.

The facts have a special interest, from this older group of mammals not having been previously met with in this district. It is to be hoped that when we can investigate these important beds more thoroughly we may get some light thrown upon the relation of man to these extinct animals, and of both to the Glacial period, undoubted deposits of which occur in other caves hard by.

Great credit is due, amongst others, to Mr. Walter Morrison, M.P., and to Messrs. John Birkbeck, Sen. and Jun., who have spared neither time, trouble, nor expense, and that in face of many discouragements.

R. H. TIDDEMAN

NOTES

THE belief in the safety of Dr. Livingstone caused by the telegrams which we published a fortnight ago, has been strengthened by further intelligence received since our last issue. The following telegram was to hand in London on Saturday last by the Falmouth, Gibraltar, and Malta Telegraph Company :—"Kirk reports from Zanzibar Livingstone safe at Unyanyembe. Visited north end of Tanganyika. Rivers said to flow into Lake Tanganyika. Stanley near the coast with letters. —GOVERNOR." No date is attached to the telegram ; but at the meeting of the Royal Geographical Society on Monday evening, Sir Henry Rawlinson stated that he considered all doubt now to be removed, and that the intelligence now in hand is really authentic He laid great stress on the well-known cautiousness of Dr. Kirk in receiving and communicating information respecting Dr. Livingstone. The following despatch from the Sultan of Zanzibar to Sir H. Rawlinson was read at the meeting :—"In the name of the Most Merciful God.—To our esteemed friend, Sir Henry Rawlinson. May the Almighty preserve him in health and happiness.—Your friend is quite well, and the object of our letter is to inform you that at the auspicious moment of our safe return from performing the pilgrimage to the holy cities of Mecca and Medina, my friend the Consul called on me and presented to me Lieutenant Dawson and his companion, and at the same time he delivered to me the letter from Her Majesty's Secretary of State for Foreign Affairs, Earl Granville, and also the gift presented by the Royal Geographical Society, through the President. And it has pleased me much to do that which is considered advisable, and that I am enabled to aid the people in their search for my friend Dr. Livingstone, and I pray God that certain information regarding him may soon be received, and I will give my aid to those gentlemen whom you have sent in attaining their object. And the Consul having requested me to grant the use of my steamer to the above gentlemen to convey them to Mombassa to procure men to accompany their expedition, I have done so, and, please God, I will continue to render assistance to those whom you have sent in your endeavour to explore the mysterious regions of the unknown country, because their object is praiseworthy, and tends to increase our knowledge of what the Almighty has created in these our countries.—From your friend, BURFASH BIN SAYYID.—Dated Zanzibar, the 5th day of Safr, year 1289 of Hejira, corresponding with the 14th April, 1872." Further telegraphic intelligence may be expected at any moment, and should this arrive we purpose next week to resume the present state of our knowledge respecting Dr. Livingstone's safety.

WE learn with great regret, from the scientific editor of *Harper's Weekly*, of the death of Dr. William Stimpson, late Secretary of the Academy of Sciences of Chicago. Dr. Stimpson's health has been quite precarious for several years past, making it necessary for him to proceed every winter to the warmer climate of Florida, and the past winter was spent by him in the same region. He was engaged in the earlier part of the season on board the United States Coast Survey steamer *Bache*, in superintending a series of dredgings, which, however, he was compelled to abandon through increasing ill-health, and returning not long since to the residence of his father-in-law, near Baltimore, he became gradually worse, and died there on the 26th of May. For a time a pupil of Prof. Agassiz at Cambridge, Dr. Stimpson made his first mark as a scientific author in 1851, in a work on the shells of New England, which was soon followed by a paper on the marine invertebrates of Grand Manan, published by the Smithsonian Institution in 1853, and which is still a standard work on the zoology of the mouth of the Bay of Fundy. Shortly afterwards he was appointed zoologist to the North Pacific Exploring Expedition, in which he was occupied for several years. When the late Mr. Robert Kennicott went to Alaska, in 1865, in the service of the Russian Telegraph Expedition, Dr. Stimpson moved to Chicago to take charge of the general affairs of the Chicago Academy of Sciences, and maintained that connection until his death. As a scientific investigator Dr. Stimpson occupied a very high rank for the thoroughness of his researches and the clearness and accuracy of his descriptions, in these respects leaving nothing to be desired. No one, with the exception, perhaps, of Prof. Dana, has described so many new species of marine animals as he. The detailed accounts of his new species, forming a large number of valuable zoological monographs, with large numbers of illustrations, and nearly ready for publication, were unfortunately all destroyed by the Chicago fire, together with most of the types of his species—a calamity which of course affected him severely, and in all probability materially influenced the state of his health. Among these works were synopses of the mollusca of the East coast of North America, and of the crustacea of both coasts, to be published by the Smithsonian Institution.

IT is rumoured that the dignity of K.C.B. is about to be conferred upon Mr. G. B. Airy, Astronomer Royal, and President of the Royal Society.

THE Albert medal of the Society of Arts has been awarded by the Council this year to Mr. Henry Bessemer, "for the eminent services rendered by him to Arts, Manufactures, and Commerce, in developing the manufacture of steel." The Conversazione of the Society will be held on Wednesday, June 19, at the South Kensington Museum.

MR. CHAMBERS, F.R.S., Superintendent of Colaba Observatory, has been presented by the Bombay Harbour Board with a valuable gold watch and chain for his service towards the port in putting up a time ball.

THE examiners in the Natural Science School at Oxford, Dr. W. Ogle, Mr. R. H. Bosanquet, and Mr. A. W. Reinold, have issued the subjoined Class list :—Class I. : Henry Cooper, All Souls' ; J. P. Earwaker, Merton ; C. J. Moullin, Pembroke. Class II. : H. Green, Queen's College. Class III. : E. C. D. Fox, Exeter. Class IV. : J. A. Lloyd, St. John's.

THE following ladies have passed the examination for special certificates of higher proficiency at the University of London :—In Mathematics and Mechanical Philosophy, Mary Stewart Kilgour, Ladies' College, Cheltenham ; in Geology and Palæontology, Laura Gertrude Eaton, Ladies' College, Cheltenham ; in Political Economy, Jane Ellen Harrison, Ladies' College, Cheltenham ; and in Harmony and Counterpoint, Mary Amelia Bennett, North London Collegiate School for Ladies.

PROF. HUMPHRY, F.R.S., will commence his Course of Three Lectures on Human Myology at the Royal College of Surgeons on Monday, June 17, at 4 P.M. They will be continued on Wednesday and Friday at the same hour. The lectures will discuss the morphology and teleology of the muscular system of man.

A TELEGRAM from Madras, printed in the *Times*, states that a court of inquiry is being held, with closed doors, on the conduct of Mr. Pogson, the Government Astronomer, who seems to be held responsible for the damage done by the late disastrous cy-

clone. Whether it is thought that he could have prevented the cyclone does not appear.

REPORTS have been received from Prof. Agassiz and his party on the *Hassler* up to the 18th of March, at which time they had reached the coast of Patagonia. They were busily engaged in dredging and carrying on explorations along the shore, with a very fair measure of success. The details have not yet been announced, but we trust we shall have an opportunity before long of presenting these to our readers.

THE Annual Report of the Trustees of the Museum of Comparative Zoology at Cambridge, U.S.A., for 1871, has made its appearance, and presents the usual satisfactory account of progress in the preceding twelve months. No institution of the kind in America, and few anywhere, has so extensive and thoroughly organised a corps of scientific assistants (amounting to between thirty and forty) as that at Cambridge; and, with the immense amount of material constantly coming in, the result in greater part of Prof. Agassiz's indefatigable personal labours, supplemented by purchases of entire collections, it is not to be wondered at that the museum is rapidly occupying the foremost rank among such establishments. Prof. Agassiz, the director, calls attention to his expected absence from the country in the expedition of the *Hassler*, gives an account of the arrangements made temporarily to supply his place, and presents the special reports of the various assistants upon the work accomplished in 1871, and to be continued during the year 1872.

AMONG the more interesting collections lately received by the Smithsonian Institution at Washington, in the department of ethnology, is a mummied human head, retaining all the form and features of life, including hair, lips, &c., but reduced by some peculiar process so as not to exceed the size of an ordinary fist. These heads are found among the Javaro tribes in the province of Chimborazo, In Peru, and are said to be of great antiquity, there being no indication of recent preparation. They are believed to be the heads of enemies slain in battle, and preserved in this way as trophies of victory. The interior of the head has been entirely emptied of flesh, bones, and brain; and the skin, which alone remains, by its contraction is thickened to the amount of more than an eighth of an inch. The lips are closely compressed, and through them are strung a series of knotted cords, which in their character call to mind the guipos of the ancient Peruvians. There is also a cord which is knotted inside the top of the head, by which it is suspended. No satisfactory explanation of the mode of preparation has been given, although there is a tradition that it is effected by introducing heated stones or sand into the cavity after the removal of the portions of the head referred to.

THE Transactions of the Norfolk and Norwich Naturalists' Society for 1871–72 show evidence of good work being done by its members. The president, in his address, speaks of the satisfactory progress made in the important task which the Society has in hand, of compiling well-authenticated, and, as far as possible, complete lists of the fauna and flora of the county; and the following papers are printed in the Report—some of them, although referring to local subjects, of more than local interest:—"On the Occurrence of the Ringed or Marbled Seal (*Phoca hispida*) on the Norfolk Coast," by T. Southwell; "Scoulton Gullery," by H. Stevenson; "The Norfolk Broads and Meres Geologically Considered," by J. E. Taylor; "Further Notes on Coast Insects found at Brandon," by C. G. Barrett; "The Marine Mollusca of the Norfolk Coast," by F. W. Harmer; "A List of Land and Freshwater Shells found in Norfolk," by J. B. Bridgman; and "On the Spongeous Origin of Flints," by F. Kitton.

WE have received from the Royal Cornwall Polytechnic Society, Falmouth, a list of a large number of subjects in which prizes and premiums will be awarded in the course of the present season. The fortieth Annual Exhibition of this Society will open on Wednesday, August 21. Medals and prizes in money will be awarded in the following Departments:—Mechanics—Machinery and Models; Mechanical and other Scientific Inventions and Improvements; Specimens of Naval Architecture; Essays and Scientific Papers, &c. Fine Arts—Pictures and Drawings by Professional Artists and Amateurs, Sculpture, Architectural Drawings and Models, and Specimens of Ornamental Art. Photography—Photographs by Professionals and Amateurs. Natural History—Essays, Local Observations, Collections of Specimens, &c. School Productions—Mechanical and Freehand Drawings, Specimens of Penmanship, &c. Plain Needlework, &c., British Lace, and all objects of interest connected with Science and the Fine and Industrial Arts, which may be considered deserving by the Judges. List of Prizes and Premiums, and all further information, may be obtained from the Secretary, J. H. Collins, F.G.S., Polytechnic Hall, Falmouth.

SCIENCE and Art teaching seems to be flourishing in Plymouth, if we may judge from the number of papers worked at this year's examinations (just concluded) by the students of the Charles Science and Art Schools. Three hundred and thirty papers have been sent up in the various subjects, being an increase over 1871 of fifty-six papers, or 20 per cent. Owing to the Department holding the examinations in several subjects in one evening, students are prevented from being examined in more than one of these, which will, in most cases, account for the falling off in those few cases where there is a decrease.

MR. N. VON MACLAY, who is in charge of a Russian scientific exploration of the Atlantic and Pacific oceans, reports to the Academy of Sciences of St. Petersburg that on the passage of the *Witjas* from the Cape de Verde Islands to Rio he made an experiment on the 3rd of February for the purpose of determining the temperature of the sea at a depth of 1,000 fathoms in the region of calms, about 3° north latitude and 24° west longitude. The temperature of the water at this depth was 38·30° F., that of the surface water being 81·68° F. It is interesting to compare this with the temperature obtained during the past winter by the Coast Survey steamer *Bache*, at about the same depth, in the deep water between Cuba and Yucatan, in the latter case the temperature amounting to about 39 50° F.

IT seems almost impossible to exhaust the richness of the deposits of vertebrate fossils of the Western territories of the United States, Prof. Leidy having lately added to the number by the description of two extinct tapir-like animals, one about the size of a raccoon, and the other about the size of a rabbit, and an insectivorous animal of the dimensions of the hedgehog. The are from the tertiary formation of Wyoming Territory.

Harper's Weekly notes that a remarkable fact connected with the interchange of animal species between Europe and America is seen in the frequency with which North American birds occur in England, and the scarcity of European birds in America. Nearly seventy species of the birds characteristic of the American fauna have so far been detected in Great Britain, the latest announcement of this kind being that of the black-billed cuckoo, which was taken at the end of September 1871 in Antrim, ten miles from Belfast. Very few of the European land birds have been found in North America, with the exception of a few species that are really Arctic in their distribution, although less frequently seen in the New World than in the Old. The water-birds of Europe are more common as stragglers. Among them we may mention the English green-winged teal, the widgeon, the woodcock, &c. The entire list, however, does not amount to a dozen species. The causes of this difference are doubtless to be met with in the comparative prevalence of certain winds. Most of

the captures of American species take place in Ireland in autumn and early winter, and in all cases are species belonging to the northern portion of America which migrate southward at the close of the breeding season. At that time the prevailing winds are from the west, and the birds in their flight become confused, and are carried across by the winds, taking an occasional rest on passing vessels.

MR. J. COBBIN, of Durban, forwards to the *Natal Colonist* the following account of a "sea-serpent" seen by him:—"During my late passage from London, I saw no less than three sea-serpents, but an account of the last will suffice. On 30th December last, on board the *Silvery Wave*, in lat. about 35′ 0″ S., and long. 33′ 30″ E., at 6.20 P.M. solar time, an enormous serpent passing nearly across our bows compelled the alteration of our course. He was at least one thousand yards long, of which about one-third appeared on the surface of the water at every stroke of his enormous fan-shaped tail, with which he propelled himself, raising it high above the waves, and arching his back like a land-snake or a caterpillar. In shape and proportion he much resembled the cobra, being marked by the same knotty and swollen protuberance at the back of the head on the neck. The latter was the thickest part of the serpent. His head was like a bull's in shape, his eyes large and glowing, his ears had circular tips and were level with his eyes, and his head was surmounted by a horny crest, which he erected and depressed at pleasure. He swam with great rapidity and lashed the sea into a foam, like breakers dashing over jagged rocks. The sun shone brightly upon him; and with a good glass I saw his overlapping scales open and shut with every arch of his sinuous back coloured like the rainbow."

ABNORMAL DISPERSION OF BODIES WITH SURFACE-COLOURS *

THESE memoirs relate to the abnormal phenomena of dispersion produced by certain bodies which reflect the rays of some colours in the manner of transparent media, and those of other colours in the manner of metals.

In transparent bodies the velocity of light is less than in a vacuum, and the index of refraction increases as the length of undulation diminishes, whereas, in the case of metallic bodies, theory leads to essentially different results. From the researches of Jamin on the elliptic polarisation of light reflected by metals, and from the more recent experiments of Quincke, it appears that the formulæ of Cauchy, Beer, and Eisenlohr give for certain metals, as gold and silver, an index of refraction less than unity, whence it follows that in these metals the velocity of light is greater than in the vacuum. Cauchy's theorem, verified by the experiments of Jamin, likewise shows that the index of refraction in metals varies with the angle of incidence, and that in most metals dispersion takes place in a manner opposite to that which occurs in transparent bodies, that is to say, that the rays of shortest wave-length are less refracted than those whose undulations are longer.

The only physicist who has hitherto attempted a direct verification of these theoretical results is Quincke; but his experiments have yielded contradictory results according to the method employed, and have therefore afforded no decisive information as to the indices of refraction and dispersion of metals. Kundt, in studying the properties of a particular class of bodies which approach the metals in their optical properties, has succeeded, if not in determining the absolute values of their refractive indices, at least in observing certain anomalous phenomena of dispersion, which appear to indicate the direct road towards a new verification of the theoretical formulæ.

The bodies in question are media intermediate between transparent bodies and metals, inasmuch as they behave like metals towards rays of certain colours, and like transparent bodies towards rays of other colours; they also reflect light with a certain degree of metallic lustre. These substances may be included under the denomination of *bodies with surface-colours*. Most (but not all) of them are strongly tinctorial, and exhibit, both in solution and in small fragments, a beautiful coloured transparency; such are most of the aniline-dyes, indigo, carthamine, potassium-permanganate, &c.

The optical properties of these bodies have been studied by Brewster, Haidinger, Stokes, and several others, the chief result of whose researches is the law, first enumerated by Haidinger, that the light transmitted by these media is exactly or nearly complementary to the light reflected from their surfaces, and, therefore, to the colour of the surface. Moreover, Dale and Baden Powell observed that indigo and Prussian blue, in reflecting light, polarise it elliptically, like the metals; and von der Willigen determined the reflection-constants of pale indigo, and found that the principal angle of incidence diminishes from the line B to E, and then increases from E to G.

The author's views respecting these bodies are based on the hypothesis that they exhibit the most general case of dispersion, that, namely, in which the index of refraction may not only increase or diminish when the wave-length in air diminishes, but may even become less than unity.

The examination of the light reflected by these bodies is alone sufficient to lead to this hypothesis. For when a medium is transparent for a particular ray, the intensity of the reflected light is expressed by the formula $\left(\frac{n-1}{n+1}\right)^2$, the value of which increases or diminishes with the increase of n, according as n is greater or less than unity. In most transparent bodies the variation of n for the different colours,—that is to say, the dispersion—is so small, that the whole of the reflected light exhibits the same colour as the incident light, so that, if the incident light is white, the reflected light is white also. Applying this formula to bodies with surface-colours, it would follow that the rays which form the superficial colour, that is to say, those which are reflected in very great proportion, should have, relatively to the others, a very large or very small index of refraction.

As the rays which form the surface-colour may have any wave-length whatever, it would follow from the formula which gives the intensity, that the dispersion of bodies with surface-colours should be, or at least might be, abnormal, in a manner which is perfectly arbitrary. It might even happen that a portion of the transmitted rays, if made to pass with a sufficient intensity through a prism of the substance, would be refracted on one side of the direction of the incident rays, and the rest on the other side. In fact, for rays which are reflected in large proportion, that is to say, rays for which the bodies under consideration act like metals, the preceding formula is not applicable, and it is necessary to employ the formulæ given by Cauchy, in his theory of metallic reflection.

These formulæ give, for the normal incidence:

$$I = \tan\left(\psi - \frac{\pi}{4}\right)$$

where ψ is determined by the relation

$$\cot \psi = \cos \epsilon \sin 2 \tan^{-1} \theta,$$

ϵ and θ being two constants to be determined by experiment, according to the relations—

$$\theta \cos \epsilon = n\ ;\ \theta \sin \epsilon = \gamma,$$

n being the index of refraction, and γ the coefficient of extinction under the normal incidence.

According to these formulæ it is not absolutely necessary, as remarked by Cauchy, that the index of refraction of metals should be very large. Nevertheless it appears from the experiments of Jamin, and those more recently made by Quincke, that the constants of elliptic polarisation have values which indicate for most metals a very large refractive index, and for silver and gold an index less than unity.

Cauchy's formulæ, applied to bodies with surface-colours—admitting that the elliptic polarisation produced by these bodies is analogous to that produced by the metals—renders probable the existence of refractive indices either very large or less than unity: hence the probability of abnormal dispersion resulting from transmission through these bodies.

When one of these surface-coloured bodies is dissolved, it preserves in solution its abnormal properties relatively to dispersion. This abnormal dispersion will be combined with the

* By A. Kundt (Pogg. Ann., cxlii. 177; Journal de Physique, 1872, p. 38) and J. L. Soret (Pogg. Ann., cxliii. 325; Journal de Physique, 1872, p. 45).

normal dispersion of the solvent; and even if no ray can then acquire an index of refraction less than unity, or be completely isolated from the rest, the succession of colours in the dispersion-spectrum of the solution will be sensibly different from that which is commonly observed.

The method employed by Kundt for the observation of abnormal dispersion in solutions of bodies with surface-colours (suggested by a memoir published by Christiansen of Copenhagen), is as follows:—A drop of the concentrated solution to be examined is placed on a glass plate, and over this drop is fixed, at an angle of about 25°, a sharp edge of a second glass plate of the same breadth as the first. At a small distance from the line of contact of the two plates, the liquid prism formed by capillary action is usually opaque; but close to the line of contact there is a prismatic layer of liquid, scarcely broader than a hair, which is transparent for most of the colours. The dispersion may be recognised by viewing through this layer a narrow and bright flame or an illuminated slit. The observations of course require a certain amount of practice, and the observer must be on his guard against deception arising from phenomena of reflection or refraction. The observation is generally made by carrying the liquid prism to the place of the glass prism in the spectroscope of Bunsen and Kirchhoff, the most favourable angle to give to the liquid prism being determined by trial.

Christiansen has observed that the index of refraction of a strong alcoholic solution of fuchsine increases from the line B to D, then diminishes rapidly as far as G, and increases again beyond that line; and the recent observations of Kundt, made as above described, have demonstrated the generality of this anomalous dispersion for surface-coloured bodies in the state of solution; that is to say, that in the dispersion-spectra of these solutions the order of the colours is not the same as in the solar spectrum, or in the dispersion-spectra of ordinary solutions. Such was found to be the case, not only with fuchsine, but with all specimens of aniline-blue and aniline-violet, with aniline-green (Hofmann's iodine green), indigo (dissolved in fuming sulphuric acid), indigo-carmine, carthamin, murexid (dissolved in potash), cyanine, potassium-permanganate, and carmine.

All the bodies in this list refract red more strongly than violet light; and in bodies for which the green forms the principal part of the surface-colour, and can be distinctly recognised in the transmitted spectrum, the green rays are the least deviated. Cyanine, aniline-violet, and aniline-blue, as well as indigo-carmine, give, therefore, in their dispersion-spectra the following series of colours: green, blue, red, the green being the least deviated. Cyanine is particularly well adapted for producing the abnormal spectrum, and exhibits the following series of colours: green, light blue, dark blue, a dark interval, red, and traces of orange. The dispersion varies however with the concentration of the solution; in dilute solutions all the bodies above enumerated exhibit normal dispersion. Potassium-permanganate and carmine exhibit reversed spectra only when their highly concentrated solutions are mixed with fine solid particles so as to form a sort of pulp, and the two glass plates are pressed strongly together. A change in the dispersion is also observed according to the angle of incidence.

Soret pours the solution under examination into a hollow prism having an angle of about 30°, and places this prism in a glass trough with parallel sides, filled with the liquid which serves as solvent. By this arrangement the reverse spectrum may be obtained with solutions less concentrated and therefore more transparent than when the liquid prism is merely surrounded by air.

If the ordinary prism of a spectroscope be replaced by a hollow prism filled with a concentrated solution of fuchsine, the reversed spectrum will be seen without the aid of the trough above described, provided the light is very strong and passes very close to the edge of the prism. With a less concentrated solution the spectrum is normal, and with a solution of intermediate concentration the spectrum is reduced to a single red line. In this case the anomalous dispersion due to the fuchsine is entirely compensated by the normal dispersion produced by the alcohol, and the result is deviation without dispersion. If now the prism containing this last-mentioned solution be immersed in a trough containing alcohol, the deviation of the rays produced by the alcohol will be almost wholly destroyed, while the abnormal dispersion of the fuchsine will remain, the red being more strongly deviated than the violet. With this arrangement it is no longer necessary to employ so strong a light, or to make the rays pass so close to the edge of the prism.

With the prism in air the deviation of the red rays is about 11° 30′; but when the prism is immersed in alcohol, the violet is scarcely deviated, the red by fifteen minutes, and the orange by twenty-three minutes.

Similar results were obtained with aqueous solutions of aniline violet and potassium-permanganate.

MR. BENTHAM'S ANNIVERSARY ADDRESS TO THE LINNEAN SOCIETY*

(*Concluded from p. 114.*)

TO Grisebach's notes on the connections of the tropical African flora with that of other countries I shall have but few observations to add. The intergrafting with the South African flora along the eastern side of the Continent may well be attributed to climate and other present physical conditions. The European character of the higher mountain vegetation of Abyssinia and the Cameroons may be indicative of the remains of that western flora, the mysteries of whose distribution north and south of the tropics I have on several occasions alluded to. The supposed evidences derived from the vegetable kingdom of a once existing connection between west tropical Africa and east tropical America through an ancient Atlantis gradually disappear on further investigation. No traces of a western Atlantic or American vegetation were met with by Mann in the mountains of Fernando Po and the Cameroons, nor by Dr. Hooker in the western Atlas of Morocco. The tropical American races found in Western Africa are chiefly confined to the coast region; they are more generally identical than representative species, and they may have been brought over in the course of ages by some of those means of transport which even now may occasionally occur, such as the Gulf Stream, as mentioned by Grisebach. You may recollect, for instance, a short notice by Dr. Dickie inserted in our Journal (Botany, vol. xi. p. 456) of a green floating mass, twelve to fourteen miles broad, crossed by Captain Mitchell in the Atlantic, within 300 miles of the mouth of the Gambia, which had evidently, as Dr. Dickie believes, come from some part of America within the influence of the Gulf Stream, probably passing between the Cape Verde Islands and the mainland of Africa. Besides algæ, the portions of this mass picked up by Captain Mitchell and examined by Dr. Dickie contained, amongst other substances, fruits, seeds and "seedling plants several inches long, all with a pair of cotyledons, roots, and terminal bud, quite fresh."† With regard to those American genera represented chiefly in eastern tropical Africa, to which I called your atttention in my paper on Compositæ, there are various considerations, requiring too much detail for me now to enter upon them, tending to show a greater probability of an ancient interchange having taken place far south of the tropics, or eastward over lands long since submerged, than across the tropical Atlantic. A prevailing eastern element in the tropical African flora has, indeed, been frequently pointed out. An interchange with continental India is so well marked north of the equator as to have been generally admitted; but south there are many distinct types represented only in Madagascar, Ceylon, Malacca, the Archipelago, or Australia. This would lead one into speculations put forward also by naturalists in other branches as to a vast continent once bridging over the Indian Ocean, and extending even far to the eastward into the Southern Pacific. Similar views derived from zoology have been recently put forward by Grandidier in a most interesting sketch of the physical geography and natural history of Madagascar, contained in No. 46 (May 11) of this year's *Revue Scientifique*. This island, whose evident antiquity and long isolation, aided by its broken surface, has enabled it to become the seat or centre of preservation of a very large number of endemic monotypes, shows also in its vegetation, besides African, many Archipelago and even Australian types. Grandidier believes that in zoology the more distant eastern connection is at least as evident, if not more so, than that with the almost adjacent African continent. In plants the African connection is decidedly predominant.

I shall not attempt to follow Grisebach in discussing the peculiarities of the remainder of his regions. We may observe throughout the same careful investigation of the climatic conditions and their influence on their vegetative character of the individual

* Delivered Friday, May 24, and abridged.

† It may require, however, as suggested by Dr. Hooker, some further evidence to show that this green mass might not as well have been brought down from some African as from some American river.

plants, and on the general aspect of the whole vegetation they constitute (*Vegetationsformen* and *Vegetationsformationen*), with the same high estimate, or we might say over-estimate, of its effects on the typical character of the species as compared with the complicated consequences of previous possession, foreign invasions, and natural selection in the struggle for life, which he seems disposed to ignore, and with the same allusions to certain mysterious creative or productive forces beyond the reach of our inquiries. A closer examination of his regions show them to be much better conceived in his phyto-climatic point of view, than I had at first thought them to be when regarded as phyto-geographical regions; and although further explorations may cause him to modify their limits in several instances, yet, in regard to all of them, the data he has collected and methodised will be found to be an important contribution to the scientific study of geographical distribution, the value of which is enhanced by copious references to the sources whence he has derived his information.

There are two general subjects upon which the bulky mass of literature continues to receive considerable accessions, both in this country and on the Continent, without perhaps adding much to our stock of information, and which would at any rate require long and patient study to extract what may be really of value; these are Darwinism and so-called Spontaneous Generation. Darwinism in some shape or other, or something under that name, enters more or less into almost all general discussions on points of natural history, especially on the Continent, and in so far as it is applicable to what the Germans call the *Descendenztheorie*, it is being more or less tacitly adopted by the great majority of naturalists; but in a general way, the comprehensive hypotheses propounded by Darwin in his various works are still the subject of much polemical discussion. Seidlitz, in his work entitled "Die Darwinsche Theorie," fills thirty pages with the mere titles of the works, memoirs, or papers published on the subject since 1859, and to this enumeration many additions might be made. Amidst this great mass it might have been expected that I should have selected some to bring specially under your notice—that I should have followed up the observations I made on the "Origin of Species" in my address of 1863, and on the "Variation of Animals and Plants under Domesticity" in that of 1868, by some notice of the "Descent of Man," as well as of some recent works of other writers, such as Mivart's "Genesis of Species;" but these have been already fully discussed by naturalists much more competent than a purely systematic botanist to deal with the question in the phase which it has now reached, and I have not met with any other work in which any connected series of observations has been methodised and brought to bear more directly on the general life-history of animals and plants. The detached observations upon several points connected with Darwin's general theories, especially those relating to dichogamy and cross fertilisation in plants, continue to be very numerous, as well as the endeavours to connect recent with geologically ancient races of both animals and plants, without, however, making any one move of importance towards the solution of the problems before us; and we are still anxiously awaiting from Mr. Darwin himself that long-promised second portion of his great digest which is to treat of the variations of undomesticated animals and plants.

Spontaneous Generation has perhaps been of late the subject of more controversy in this country than abroad. Since Prof. Huxley, followed by Prof. Tyndall, placed the matter in so clear a light at the Liverpool meeting of 1870, Dr. Bastian has returned to the charge. In his work entitled "The Modes of Origin of Lowest Organisms," he has published an account of numerous experiments further illustrating his views in opposition to those of Huxley and Tyndall, and confirming, in his mind, the theory of Archebiosis, the name he gives to what is commonly called Spontaneous Generation. On the other hand, Mr. N. Hartley has communicated to the Royal Society ("Proceedings," xx. No. 132) his experiments concerning the evolution of life from lifeless matter, which appear to have been conducted with great care, and in some measure under the guidance of Dr. Odling and Prof. Tyndall. From these he concludes that so far as our present knowledge guides us, whether we term it Spontaneous Generation, Abiogenesis, or Archebiosis, the process by which living things spring from lifeless matter must be said to be only ideal. The same number of these "Proceedings" contains abstracts of papers by Dr. Crace Calvert on the development of protoplasmic life, its influence on putrefaction, and the effect of various substances in promoting or arresting its progress, all of which papers are connected with, and in continuation of, his former experiments and conclusions tending to support the theory that this protoplasmic life is derived from invisible germs floating in the atmosphere. Dr. Bastian, at a later meeting of the Royal Society, again returned to the subject in a paper entitled "On some Heterogenetic Modes of Origin of Flagellated Monads, Fungus-germs, and Ciliated Infusoria," inserted at length in No. 133 of the "Proceedings." The experiments and observations here detailed are very interesting as to the development of these organisms in the pellicle that forms on infusions of organic matter when exposed to the atmosphere; but they do not affect the question of the origin of the living components of the pellicle itself, which he considers to have been fully proved by his own former papers, as well as by the well-known experiments of Pouchet and others, to have been evolved from lifeless matter by archebiosis A more extended work, giving the fullest details of his views of the "Beginnings of Life" is announced, but I have not yet seen it.

If, then, Spontaneous Generation may as a theory in the minds of some persons have become referred to the class of paradoxes like the quadrature of the circle, yet it is still supported by so many naturalists whose opinions are entitled to consideration, and there is so much to be said for as well as against it which appears unsusceptible of direct and positive proof, that it is likely to be long maintained as a subject of controversy, without any further much more definite result. But there is one question of a more practical nature, often supposed to be connected with it, which has excited, and is still calling for the serious attention of men of science, experience, and judgment, as well as of various Governments. I allude to those parasitical scourges which within the last thirty years have made such havoc in several important articles of European food and industry. Thirty years since, and I believe up to the fatal year 1845, the potato-disease, the silkworm-pébrine, and the oidium of the vine were unknown in Europe; and we can most of us remember how the sudden appearance and rapid extension of each in succession produced the famine in Ireland, and the ruin of so many French and Italian silk-breeders and wine-growers of the Mediterranean region, Madeira, and Bordeaux; and how for long men of science have been baffled in their efforts at ascertaining the true history of the attendant fungi, and devising an efficacious remedy. The potato-disease appears now to have settled down into one of those chronic epidemics whose varying intensity, according to season and other circumstances over which we have little control, must enter into the calculations of every potato-grower. This useful tuber can no longer, indeed, be advantageously cultivated in that wholesale manner which induced the late Thomas Andrew Knight and others to attach to it so high an economic value, but it may now again be fairly depended upon as an important article of household food.

The pébrine of the silkworm, from the latest reports I have seen of the Commissions of Lyons and other places, shows but little abatement of its intensity, although it it has in some measure changed its character, and is, it is to be feared, through the carelessness or cupidity of interested dealers, spreading even into those eastern regions which have been looked to for the supply of "seed" free from the fatal germ. The oidium, on the contrary, has been got more under control; and experience now shows that in many districts at least its ravages can be checked or entirely stopped by means within the reach of every intelligent cultivator. But within the last few years a new plague has in the south of France excited even more alarm than the oidium itself, from its insidious invasion and complete destruction of many of the most valuable vineyards; this time, however, the offending parasite is brought much more within the scope of direct scientific observation. The germs of the potato-fungus, of the pébrine, of the oïdium, are all invisible and inappreciable by any of our instruments; the history of their diffusion and early development, and even their very existence, can only be judged of from their results and other circumstantial evidence; whilst the *Phylloxera vastatrix* can be watched in every stage of its varied existence, from the first deposit of the fertilised eggs, through its several agamic generations, to the latest winged form. The researches, accordingly, which have been already applied to it have not been altogether barren of results, throwing some light even generally upon the origin and dispersion of these pests. Considerable sums of money, either from the French Government or from private subscriptions, have been applied to the purpose, and the investigation has been chiefly carried on by our foreign member, Dr. J. E. Planchon, of Montpellier, assisted by

M. J. Lichtenstein, a relative, I believe, of the late distinguished Prussian zoologist. These gentlemen, since the first discovery of the disease in France in 1868, have devoted much of their time to it. They have compared their observations with those of others who in other countries have studied the insect, especially Mons. Laliman, of Bordeaux, Mr. Riley, of Missouri, and with those of Prof. Westwood in our own country; and they have now, in a pamphlet which, by some inversion of dates not uncommon abroad, is supposed to form part of the Proceedings of the session of the French scientific congress at Montpellier in 1868, given a *résumé* of nearly five hundred memoirs, communications, or journal articles which have been published on the subject up to the close of last year (1871).

The main facts given as having been hitherto elicited as proved or probable may be shortly resumed as follows:—

The *Phylloxera*, like other Aphides, goes through a number of apterous generations of a single sex, but multiplying with enormous rapidity; for one or two individuals will lay as many as five hundred eggs, fertilised without previous copulation. It also gives birth occasionally to a winged generation of both sexes, the females of which lay only two or three eggs each.

The apterous *Phylloxera* is also dimorphous, a smooth-bodied form living in little galls formed on the leaves of the vine, where it is comparatively harmless; and a tuberculate form living in the nodules it produces on the root-fibres, causing first the smaller and then the main roots to rot, weakening, in the first instance, and finally killing the whole vine. Each form has its winged ganeration.

The insect is evidently of North American origin, although the precise history of its transmission to this country has not been ascertained. It was first described by Asa Fitch in the Transactions of the New York State Agricultural Society for 1854; but living there chiefly on the leaves of the native vines, it had not attracted any peculiar attention. More recently, however, Mr. Riley has found reason to attribute to the ravages of the subterranean form the ill success of the various attempts made to establish in America the European grape-vine. In England, where the introduction of the insect from America may be readily conceived, Prof. Westwood's attention was first called to it in 1863, and again from various quarters in 1867 and 1868, whence resulted the above-mentioned account in the *Gardener's Chronicle* for January 1869 (p. 109). With us it does not appear to have spread much, and has therefore not called for any further observation, the damp soil, the mode of treatment, or other external circumstances, proving unfavourable for the development of the underground form. But having by some means reached and established itself in the dry, naturally-drained vineyards of the south of France its general character underwent a change; natural selection at once gave an enormous preponderance to the underground over the epiphyllous form. It was first discovered there in July 1868, and by the close of that year its ravages caused a panic among the vine-growers in many parts of Lower Languedoc and Provence, similar to that which we may remember in this country on the rapid spread of the potato disease in the autumn of 1845. It was immediately made the subject of scientific investigation, which has ever since been steadily pursued. As one result Dr. Planchon inclines to believe that the oidium and the potato disease, like the *Phylloxera*, and, in former days, the American blight of our apple-trees, had all been imported from America. It would seem that all these parasites, whether insects or fungi, capable of enormously rapid and extensive propagation, remain unnoticed so long as they are kept in check by the mutual relations of their constitution, habits, food, and other circumstances in which they are placed; but that the moment that a change, often very slight, in one or other of these conditions destroys the balance, they may at once and suddenly gain the upper hand, so as to be classed in the popular mind amongst those varied phenomena collectively designed as blights. That such a change is often the consequence of the transportation of the insect from one country to another may be regarded as more probable if Riley is correct in his belief that in America, as in Europe, introduced insects, when once established, are more noxious than indigenous ones. In the case of the *Phylloxera* some clue to the nature of the influencing alteration may be derived from the success attending one of the remedies applied, the inundation and continued submersion of the diseased vineyards during the winter months. The comparative dryness of the soil in the new over that of the original station of the insect has been the change which natural selection seems to have seized upon to effect the extraordinary development of the underground form, aided, perhaps, by some slight attendant change in its constitution. Prolonged, or even temporary inundation, is not however, practicable in the majority of the South of France vineyards, nor, indeed, in any of those producing the best wines. Amongst other remedies, soot (the soot of wood-smoke I presume) promises to be one of the most efficacious applications.

Amongst the various publications which these phenomena have called forth, we may still see cropping up not unfrequently the popular notion that they are blights mysteriously connected with meteorological conditions, against which it is vain to struggle; but, fortunately, the need of separately investigating every one of them is becoming generally recognised. In France, Government has appointed special commissions for inquiries into the silk and wine diseases. In Germany the ravages committed by insects on their forests have been the subject of various works, published chiefly under the patronage of the Austrian Government and scientific associations. In North America Mr. Riley, as Missouri State entomologist, makes annual reports on noxious insects to the Board of Agriculture of that State, pursuant to an appropriation for this purpose from the Legislature.* In Italy a special institution has been formed at Padua, under official patronage, for the study of cryptogamic parasites; and our Royal Horticultural Society is also making arrangements for the special encouragement of the study of economic entomology. To these and similar institutions it is the duty of science, in the interest of mankind, to give its unqualified support, to divest itself of all preconceived theories and prejudices, to avoid those polemical discussions which appear to have gone beyond the security they give for the exhibition of facts in all the various points of view they may bear, but impartially to study every detail connected with these scourges, which have so much increased during the present century, fostered, perhaps, by the advance of civilisation and high cultivation.

SCIENTIFIC SERIALS

THE *Lens* (No. 2), April, 1872.—This second number of the new American journal of microscopy contains little that is new or of importance. "The Flora of Chicago and its Vicinity" is continued by H. H. Babcock from the previous number, as is also the "Conspectus of the Families and Genera of the Diatomaceæ," by Prof. H. L. Smith. This second part of the Conspectus is occupied by a "Synonym Register," which promises to be useful, and is in fact the most complete attempt of the kind yet made. "Microscopical Memoranda for the use of Practitioners of Medicine," by Dr. J. J. Woodward, is also a continuation, and consists of two parts, viz., staining the sections, and mounting the stained sections in Canada balsam. There is also a chapter "On the double marking of *Triceratium*," by the same author, accompanied by a Woodbury print of two frustules of *Triceratium fimbriatum*. "On the effect of the reversal of the current of the Chicago River on the Hydrant Water," by H. H. Babcock. "Where to search for Diatomaceæ" is a reprint from the *Intellectual Observer*, and "Alternation of generation in Fungi," by M. C. Cooke, from NATURE. This number of the *Lens* is increased to double the thickness of the previous one by the insertion of the catalogue of optical instruments manufactured or sold by an American firm in Philadelphia and New York.

IN the *American Naturalist* for April we have an article by Dr. J. J. Woodward on the Use of *Amphipleura pellucida* as a Test-object for High Powers, illustrated by a photograph. Dr. Abbott concludes his exhaustive paper on the Stone Age of New Jersey; and the remainder of the number consists of reviews and book notices, and of short paragraphs under the headings of the various departments of natural science.

In the number for May is a note by Mr. J. G. Henderson on the use of the rattles of the rattlesnake, in which he comes to a somewhat different conclusion from Prof. Shaler, believing that it is protective in its object.—Mr. J. A. Allen contributes some ornithological notes from the West, the present communication referring to the birds of Kansas.—Prof. A. H. Tuttle gives the result of a careful study of the genus *Urella* of Flagellate Infusoria, illustrated with a number of woodcuts.

* Since writing the above I have seen a proof-sheet of a portion of the forthcoming fourth report of the Missouri State entomologist, Mr. Riley, in which he enters into further details of the history of the *Phylloxera*, collected during a recent visit to Europe, as well as from closer observations on the subject made in America, where it appears to be acquiring more serious importance. I have not, however, yet seen enough of the report to learn what further conclusions Mr. Riley may have arrived at.

There are also useful practical papers of instructions for herborising, for collecting micro-lepidoptera, and for preparing birds' eggs; as well as a large number of interesting paragraphs of information under the heads of the natural sciences.

THE *Journal of the Frankin Institute* for May contains a good drawing of Danks's patent puddling furnace, and a large number of paragraphs under the head "Items and Novelties." The substantial articles include a continuation of Prof. Nourse's paper on inter-oceanic communication across Central America; Mr. John Warner on the diamond rock drill; Mr. C. Van Bruol on a new modification of the Holtz machine, and a list of auroral displays during February at a number of stations in the United States; and the continuation of various other papers commenced in the preceding numbers.

THE number of the *Transactions of the Linnean Society* just published, vol. xxix. part I, contains the commencement of Colonel Grant's Botany of the Speke and Grant Expedition, including an enumeration of the plants collected during the journey of the late Captain J. H. Speke and Captain J. A. Grant from Zanzibar to Egypt in 1860-63. The determinations and descriptions of the species are by Prof. Oliver, Mr. J. G. Baker, and other botanists connected with the Kew Herbarium; while Colonel Grant writes an introductory preface, alphabetical list of native names, and notes. It is prefaced by a good map of the whole of the journey; and illustrated by thirty-seven drawings on stone of new or remarkable species. The total number in the whole paper will be 100.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, May 22.—Prof. Morris, vice-president, in the chair. The following communications were read:—I. A communication from the Right Hon. Earl Granville, inclosing a report from H. M. Minister at Rome, relating to the recent eruption of Vesuvius. 2. "On the Phosphatic Nodules of the Cretaceous Rock of Cambridgeshire," by the Rev. O. Fisher, M.A., F.G.S. This paper contained an attempt to explain the origin of the phosphatic nodules which lie in a thin bed at the base of the Chalk in Cambridgeshire, and are largely extracted by washing the stratum for the purpose of making superphosphate of lime. Two hundred and seventy tons per acre, at the rate of fifty shillings a ton, represents the valuable yield of the deposit, which is followed to the depth of about 18 feet. The nodules and other fossils of the bed are chiefly derivative, forming a concentrated accumulation from a deposit belonging to the Lower Cretaceous period. Some of the fossils are, however, believed to be indigenous to the deposit. *Plicatulæ* are attached to all the derivative fossils and nodules, and the sharp, broken surfaces of the latter, with *Plicatulæ* on them, show that they were mineralised before they were deposited in their present *gisement*. The green grains of chlorite have been drifted into patches. Certain calcareous organisms are preserved, but many genera of molluscs only occur as casts in phosphate of lime. The phosphatic matter has been determined in its deposition by *animal* substances. There are two chief varieties of the "ordinary" nodules. The first are amorphous, or else finger-shaped; the second formed like a long cake rolled partially or wholly upon a stick. The surface of these two kinds of nodules is coriaceous and wrinkled, and they usually show marks of attachment to some foreign body. Certain species, clearly zoophytes, are converted into phosphatic nodules, and, when sections are made of these, they are found to show under the microscope structures and spiculæ allied to those of Alcyonaria. Slices of the *common* nodules show similar spicular, and occasionally reticular structure. When casts in plaster are made from *Alcyonium digitatum*, and coloured to resemble the nodules, the similarity in general form and structure of surface is very striking. The phosphate was probably segregated by the animal matter from its solution in water charged with carbonic acid, which is a known solvent of the phosphate; an analysis of the matrix has proved that phosphate of lime is appreciably present in it. The author doubted the derivation of the nodules from the denudation of the subjacent Gault, and exhibited a collection of these to show that they were distinguished by more stunted growth. The deposit was on the whole considersd to represent the thin band with similar fossils at the base of the Chloritic Marl, as seen in the West of England, in which district it is underlain by the true arenaceous Greensand. The absence of the true Greensand was attributed to the intervention of the old palæozoic axis of the London area; and it was finally suggested that a similar axis might stretch from Leicestershire to Harwich, causing the change in character of the Lower Cretaceous beds between Cambridgeshire and Norfolk.—3. "Some observations on the Upper Greensand formation of Cambridge," by Mr. W. Johnstone Sollas. The Greensand Formation consists around Cambridge of a Chalk marl containing harder portions of a different nature disseminated throughout it, these are separated from the Chalk Marl by levigation, and sorted by sifting into larger bodies, consisting almost entirely of the so-called "coprolites," and smaller bodies—the so-called "Greensand." The author gave a general account of his conclusions regarding the "coprolites," reserving details for a future communication. Of all the facts the most obvious is the connection between presence of "coprolite" and former existence of organic matter; when coprolite is found incrusting a bone or other fossil, it is precisely on those parts where animal matter adhered most abundantly. Instances were cited, as in *Palæocorystes*, where the absence of animal matter on the back of the carapace is marked by an absence of phosphatic incrustation; while the sternal side, where animal matter could easily escape, is often altogether embedded in "coprolite." Coprolites are the fossilisation of organic matter derived from very various sources. In many cases they owe their origin to sponges, almost certainly so in the case of cylindrical coprolites perforated by a cylindrical cavity, now filled up with Chalk Marl; other forms have an *allied* origin. Thus coprolites are the flints of the Gault. The Greensand is a mixture of calcareous, silicious, and dark-coloured grains of uncertain chemical composition. The calcareous grains consist of sponge spicules, minute shells, fragments and prisms of shell substance, bivalve entomostraca, microscopic corals, minute echinoderm species, polyzoa, and foraminifera. A list was given of the foraminifera, the abundant occurrence of *Lagena* here being particularly noticed, as, with the exception of *L. apiculata*, mentioned by Reuss, the genus had not before been noticed below the Maestricht Chalk. The silicious grains consist of fragments of various rocks, some of volcanic origin. The dark coloured grains are coprolitic *débris* and true green grains. The green grains are almost all casts of foraminifera, derived chiefly from *Bulimina*; others are derived from *Lituola*, *Rotalina*, *Globigerina*, and other forms. Some green grains of exactly the same nature had been found by the author in the silicious sand of Blackdown.—Prof. Phillips was glad that his casual remark had produced such satisfactory results as the paper he had heard. It was satisfactory to find that the bulk of the phosphatic nodules exhibited such marked traces of an organic origin. Though he had to some extent been prepared for this, it appeared that the view might be extended much further than would at first sight have been anticipated. He drew an analogy between the preservation of the forms of sponges in their silicified fossils with that of the soft organic bodies in the Greensand by phosphatic matter. In each case the surrounding water contributed a large amount of either flint or phosphate of lime, which was segregated and accumulated round certain centres or nuclei of organic bodies.—Prof. Ramsay inquired from what sources the abundance of phosphatic matter requisite for the production of these fossils could have been derived. In such thin strata, which seemed to indicate a transition from a land to a marine surface, it was a matter of great difficulty to his mind to account for so great an abundance of phosphatic matter.—Mr. Godwin-Austen remarked that phosphoric acid was largely present in sea water, and instanced the present seas, where, as on the Newfoundland banks, fish existed in enormous quantities, and no doubt also phosphatic matter. The Cambridge beds, though so rich, were by no means unique of their kind. He referred to a paper communicated some years ago to the Society by Mr. Payne, as affording many interesting particulars with regard to such beds. He considered that much of the phosphate attaching to decaying animal matter might have been derived from comminuted excrementitious deposits floating in the water.—The Rev. T. G. Bonney remembered a fact quoted by the late Dr. Mantell as to the large quantities of dead Mollusca which had been observed floating down some of the American rivers, and which had been regarded as a plentiful source of phosphatic matter. Small fishes might also have furnished a considerable quantity, and their value as manure was recognised at the present day. With regard to the nodules being Alcyonaria or sponges, he observed that what spicules he had seen appeared more like those of sponges. He agreed with Mr.

Sollas as to the foraminiferal origin of many of the green grains. He did not agree with Mr. Fisher in attributing all the nodules to the bed in which they were found, but thought that a considerable portion might be referred to the upper part of the Gault. In proof of the washing the Gault near Cambridge had undergone, he mentioned the occurrence there of a number of boulders of rocks quite foreign to the district.—Mr. J. F. Walker thought that most of the fossils of the phosphatic band at the base of the Chalk-marl were derived from the Gault, whilst the bed differed from chalk only by green grains becoming gradually more abundant. The fossils were generally much water-worn, the characteristic fossils of the Warminster Greensand were absent, and the most abundant fossils were all of Gault species. It seemed that wherever these accumulations of phosphatic matter occurred denudation had taken place, and that they were the residuary heavy materials of a large thickness of rock. This might also be observed in the Upware and Potton beds.—Mr. Whitaker observed that the Upper Greensand thinned out as much to the south as to the north of London. He inquired as to the alleged abundance of phosphate of lime in the upper part of the Gault. He doubted whether the thin band at Cambridge could represent the great thickness of Upper Greensand which was to be found in some other districts. He regarded it rather as a gradual passage into Chalk, though the line of demarcation was evident on the Gault. Though agreeing with Mr. Walker as to some of the fossils having been derived from the Gault, he could not regard them all as having come from that source.—Mr. Meyer thought that the Greensand had always been absent in the Cambridge district, and mentioned the occurrence of a bed of much the same character as that in question at Knighton in the Isle of Wight.—Mr. Forbes pointed out that the amount of phosphatic matter in fishes was so small that it was difficult to assign such an abundance as that described to this source. In limestones almost entirely composed of shells, he could find only from $\frac{1}{2}$ to 1 per cent. of phosphate of lime. Even with true coprolites, he thought that they had become richer in phosphate since their deposition; but whence it was derived he would not pretend to say. He thought this question of derivation still open.—Prof. Morris mentioned the occurrence of similar deposits near Wissant, on the coast of France, and near Calne, in Wiltshire. He called attention to the extremely quiet nature of the sea in which the phosphatic bed had been deposited, and observed on the existence in recent times on certain sea-shores of ooze containing a large amount of phosphatic matter.—Mr. Fisher, in reply, stated that he had in his paper but slightly touched on the sources of derivation of the phosphate of lime; but as to the possibility of that substance being localised and derived in large quantity from fish, he pointed out that the principal manure of modern times, guano, was derived from this source. He alluded to the possibility of some process of dialysis having contributed to the segregation of the phosphate. He disputed the identity of the nodules in the Gault and in the Chloritic Marl of Cambridge. As to the character of the fossils, he regarded it as the same as that to be found in a thin band at the base of the chalk in parts of Hants and Dorset. Mr. Sollas had examined sections of the fossils from the Cambridge beds under the microscope, but had failed to find the canals or tuberculated spicules characteristic of Alcyonaria. He had, however, in the sand found numerous indisputable sponge spicules. He had, moreover, found in sections of the coprolites spicules such as were regarded by Dr. Bowerbank as characteristic of sponges. He hoped, however, to recur to the subject. Both Mr. Fisher and himself concurred in removing these nodules from the category of concretions, and placing them under the head of organic fossils. The transported blocks in the beds bear evidence of glacial action, and he considered had been brought from Scotland or Scandinavia. The cold sea then existing at the base of the Scandinavian chain of mountains flowed southwards over the bottom of the ocean, carrying with it mineral matter in solution, particularly phosphates, so that in this way he thought that some portion of the phosphatic matter was derived from the decomposition of the volcanic rocks north of Lammermuir, which were rich in this substance, and of which rocks he had found fragments near Cambridge. He considered that, under certain circumstances, the phosphate matter present in water would combine with animal matter, and hoped at some future time to offer some remarks on this subject to the Society.

Zoological Sooiety, June 4.—Prof. Flower, F.R.S., V.P., in the chair. Mr. G. Dawson Rowley exhibited a specimen of *Zonotrichia albicollis*, which had recently been captured alive near Brighton, being the second recorded instance of the occurrence of this bird in the British Islands.—Mr. P. L. Sclater exhibited a specimen of the American Black-billed Cuckoo (*Coccyzus erythropthalmus*) killed in Ireland. This specimen had been referred by Mr. Blake Knox to the Yellow-billed Cuckoo (*Coccyzus americanus*), and by Lord Clermont, subsequently, to the Black-billed species (*C. erythropthalmus*). Mr. Sclater remarked that there could be no question of the latter determination being correct.—The Secretary communicated extracts from a letter received from Captain Henry Pain, of the S.S. *Scanderia*, on the habits of the Sea-Lion (*Otaria jubata*) and Fur Seal of the Falklands (*O. falklandica*).—Prof. Owen, F.R.S., read a paper on Dinornis, being the nineteenth of his series of memoirs on this genus. The present communication contained the description of a femur, indicative of a new genus of large wingless bird (*Dromornis australis, Ow.*) from a post-tertiary deposit in Queensland, Australia.—Prof. Flower, F.R.S., read a note on some points in the anatomy of the Two-spotted Paradoxure (*Nandinia binotata*), and showed that the cæcum is absent in this animal, contrary to the almost invariable rule which distinguishes the Arctoid subdivision of the Carnivora.—A communication was read from Dr. John Anderson, Curator of the Indian Museum, Calcutta, on the osteology and dentition of *Hylomys*. Dr. Anderson came to the conclusion that this form was most nearly allied to *Gymnura*, and belongs to the Erinaceidæ.—Mr. E. T. Higgins read a paper describing some new species of shells discovered by Mr. Clarence Buckley in Ecuador.—Mr. F. Moore communicated a paper by Captain Thomas Hutton on the Bats of the North-Western Himalayas, in which several new species were described.—Mr. P. L. Sclater read some additional notes on rare or little known animals, now or lately living in the Society's Gardens.—Dr. J. Murie read a paper on the Indian Wild-Dog (*Canis dukhunensis*); his observations being based on two specimens formerly living in the Society's Gardens. After noting points in their anatomy, Dr. Murie specially referred to the variations in the pelage and skulls, which distinguish the four supposed species of the genus. These he was inclined to regard only as one species, viz. *C. primævus*, with geographical varieties.—A second paper by Dr. Murie contained observations on the Bornean Ape (*Macacus maurus*), being the first of a series of papers on the rarer forms of this group.

Entomological Society, June 3.—Prof. Westwood, president, in the chair. Mr. Stainton exhibited specimens of a very large black *Coccus* on the cork oak found at Cannes by Mr. Moggridge. Also specimens of *Antispila rivillei*, bred from larvæ mining the leaves of the vine at Massa di Carrara, found by the Hon. Miss de Grey. This insect was first discovered in the island of Malta about 1750 by De Riville, but was not again noticed until 1871.—Prof. Westwood exhibited a large cottony mass, in which were enveloped the cocoons of a minute parasitic Hymenoptera which infested a large caterpillar in Ceylon; one of these caterpillars had produced at least 1,000 of this parasite. Mr. F. Moore had observed a similar occurrence in the larva of a large *Bombyx* from Bombay.—Prof. Westwood also exhibited apple twigs, the buds of which were destroyed by a larva, apparently of a *Tortrix*.—Mr. Higgins exhibited a selection of magnificent species of *Cetoniidæ* from Java obtained from Dr. Monicki.—Mr. Weir observed that he had recently found the larvæ of *Gonopteryx rhamni* feeding upon *Rhamnus alaternus* in his garden at Blackheath; this insect had not been seen there during sixteen years, and not until he planted this *Rhamnus*, which it immediately discovered, although so totally unlike the two indigenous species of the genus on which the larvæ habitually feed here.—Mr. Miller called attention to a paragraph in the daily newspapers concerning the enormous increase of ants on the island of May to such an extent as to render the land useless to the lighthouse-keepers. The subject had been brought to the notice of the Northern Lighthouse Commissioners, and a visit had been made to the island for the purpose of investigating the matter.

Linnean Society, June 6.—Mr. G. Bentham, president, in the chair. The president appointed Mr. Geo. Busk, Dr. J. D. Hooker, Mr. John Miers, and Mr. W. W. Saunders, vice-presidents for the year. The papers read were:—On some recent forms of *Lagenæ* from Deep-sea Dredgings in the Japanese Seas, by J. W. O. Rymer Jones; On the Cutaneous Exudation of the Water-newt (*Triton cristatus*), by Miss E. A. Ormerod.

Chemical Society, June 6. Dr. Gilbert, F.R.S., vice-president, in the chair.—"On a Remarkable Salt deposited from the Mother Liquors obtained in the Manufacture of Soda," by Prof. E. T. Thorpe; "On the Composition of Ceylon Jargons," by M. H. Cochran; "On a Double Sulphide of Gold and Silver," by Mr. Pattison Muir; "On the Solvent Action of various Saline Solutions upon Lead," by the same author; "On the Magnetic Sand of Mount Etna," by J. B. Hannay; "New Tests for some Organic Fluids," by J. A. Wanklyn; "Dendritic Spots on Paper," by A. Liversidge; "On Chinoline and Leucoline," by C. Greville Williams, F.R.S. A letter from Mr. Dewar of Edinburgh was then read by the secretary on some derivatives of chinoline.—Dr. C. R. A. Wright read a paper on the "Action of Phosphoric Acid on Morphine," and Mr. W. H. Perkin, F.R.S. "A Note on the Secondary Colouring Matter produced in the preparation of Alizarine from Anthracene;" "On the Effects of Temperature on the Absorption of Gases by Charcoal," by Mr. J. Hunter. Dr. Armstrong then brought forward a series of "Communications from the Laboratory of the London Institution, No. V. On the Nitration Products of the Dibromo-phenolsulphonic Acids; No. VI. On Bromo-phenosulphonic Acid; No. VII. On the Formation of Substituted Nitrophenolsulphonic Acids," and finally the secretary read a letter which had been received from M. E. Maumené of Paris.

PHILADELPHIA

Academy of Natural Sciences, October 3, 1871.—Dr. Ruschenberger, president, in the chair. Mr. Thomas Meehan referred to some observations made by him last spring before the Academy in regard to the office of bud scales and involucral bracts. The general impression was that they were formed for the purpose of protecting the tender parts beneath. At that time he exhibited the branches of *Fraxinus excelsior* on which some of the buds were entirely naked, and others clothed with scales in the usual manner. They could scarcely be for protection in this instance, as both were equally hardy. He now had to exhibit an ear of corn which had been produced without the usual involucral bracts or husks, and yet was as perfect as if clothed in the usual way, showing that the husk was of not much importance as a protecting agent. An interesting point was that this ear had been formed on the end of a male panicle or tassel. It was not uncommon to find scattered grains of corn amongst male flowers, but a perfect ear like this he had never before seen. The ear was eight-rowed, and contained two hundred perfect grains. It was the variety known as "popcorn."

PARIS

Academy of Sciences, June 3.—Mr. A. Cayley communicated a paper on the surfaces divisible into squares by their curves of curvature, and on Dupin's theory.—A memoir by M. Yvon Villarceau on isochronous regulators derived from Watts's system was read.—M. de Pambour read a note on the additional friction due to the load of machines.—M. Le Verrier communicated some observations on magnetic declination made at Batavia and Buitenzorg during the solar eclipse of December 12, 1871, extracted from a letter from M. Bergsma, in which the author stated that this eclipse exerted no influence upon the direction of the magnetic needle either at Buitenzorg, where the eclipse was total, or at Batavia, where it was nearly so. M. Le Verrier also presented a note by M. C. Grad on the magnetic declination in Algeria, containing the results of a series of observations made at fourteen stations during the last winter.—A paper was read by M. Berthelot on the formation of acetylene by the obscure electrical discharge; and another by MM. Berthelot and Bardy on the transformation of ethylnaphthaline into acenaphthene.—A note by the Abbé David, on a new species of *Paradoxornis*, was read. This bird was obtained near Shanghai by Father Heude, and is described under the name of *P. Heudei*.—M. C. Robin presented a note by M. A. Dufossé on the noises and expressive sounds uttered by fishes.—M. Bouillaud presented some considerations on chlorosis and anæmia in the human subject, with reference to M. Boussingault's paper, read at the last meeting, on the iron contained in the blood and in food; and M. A. Dumont read a note on the distribution of the water of the Rhone at Nîmes.

BOOKS RECEIVED

ENGLISH.—Michael Faraday: J. H. Gladstone (Macmillan and Co.)—My Garden, its Plan and Culture: Alfred Smee (Bell and Daldy).—A Lecture on Science and Revelation, 2nd edition: Jas. Stuart (Longmans and Co.).—A Discourse on the Inductive Philosophy: A. C. Finch (Longmans).—First Lessons on Health: J. Berners (Macmillan).

DIARY

THURSDAY, JUNE 13.

ROYAL SOCIETY, at 8.30.—Further Experiments on the Effect of Alcohol and Exercise on the Elimination of Nitrogen: Dr. Parkes, F.R.S.—On the Spectrum of the Great Nebula in Orion, and on the Motions of some Stars towards or from the Earth: W. Huggins, F.R.S.—On Blood Relationship: F. Galton, F.R.S.—Report of further Scientific Researches in the Mediterranean, Aug.-Oct., 1871: Dr. Carpenter, F.R.S.

SOCIETY OF ANTIQUARIES, at 8.30.—Ancient Rings from Palestrina: C. D. E. Fortnum, F.S.A.—Polychrome Vitreous Beads: J. Brent, F.S.A.

MATHEMATICAL SOCIETY, at 8.—On the Surfaces divisible into Squares by Curves of Curvature: Prof. Cayley.—On Prof. Cremona's Transformation between Two Planes and Tables relating thereto: Mr. S. Roberts.—On a Manifold Correspondence of Two Planes: Dr. Hirst.—Note on a Special Case of the Anharmonic Ratio Sextic: J. J. Walker.

FRIDAY, JUNE 14.

ASTRONOMICAL SOCIETY, at 8.

MONDAY, JUNE 17.

ANTHROPOLOGICAL SOCIETY, at 8.—The Tribes of North Aracan: St. Andrew St. John.—Australian Languages and Traditions: Rev. W. Ridley.—Indian Picture Writings in British Guiana: C. B. Brown.—Exhibition of Photograph of the Tattooed Man, and Short Description: A. W. Franks.—The Ainos of Yeso: Commander H. C. St. John.

TUESDAY, JUNE 18.

ZOOLOGICAL SOCIETY, at 9.—On the Cranial Appendages and Wattles of the Horned Tragopan (*Ceriornis satyra*, Linn.): Dr. J. Murie.—On the Cetacea observed during the voyage round the world of H.I.M.S. *Magenta*, 1865–68, with the description of several new or little known species, and of a new genus of Fin-backed Whale: Prof. H. H. Giglioli.

WEDNESDAY, JUNE 19.

GEOLOGICAL SOCIETY, at 8.—On the Discovery of Palæolithic Implements in association with *Elephas primigenius* in the Gravels of the Thames Valley at Acton: Col. A. Lane Fox.—On the Evidence for the Ice-sheet in North Lancashire and adjacent parts of Yorkshire and Westmoreland: R. H. Tiddeman.—On a new Species of Coral from the Crag: Prof. P. Martin Duncan, F.R.S.

METEOROLOGICAL SOCIETY, at 7.—Anniversary Meeting.

THURSDAY, JUNE 20.

ROYAL SOCIETY, at 8.30.

SOCIETY OF ANTIQUARIES, at 8.30.

LINNEAN SOCIETY, at 8.—On the structural peculiarities of the Bell Bird (*Chasmorhynchus*): by Dr. Murie, F.L.S.

CHEMICAL SOCIETY, at 8.—On Deacon's Method of obtaining Chlorine, as illustrating some principles of Chemical Dynamics: H. Deacon.

THURSDAY, JUNE 20, 1872

LIVINGSTONE

DR. LIVINGSTONE is one of those men, becoming scarcer now in these nervous days of hurry and excitement, who do what they put their hands to with all their might. He went to Africa to discover certain regions then unknown, and especially to determine the extent and character of the great catchment basins on the eastern side of the continent. His object was not solely, or even chiefly, the advancement of geographical knowledge. In his eyes geography is only a means to an end. He hopes, through an extension of the knowledge of the interior of Africa, to call forth a spirit which may be the means of securing the great objects of his life—the extinction of the slave trade, and a permanent improvement in the condition of the negro race.

Some six years ago Dr. Livingstone landed at the mouth of the Rovuma, and disappeared from the knowledge of European seekers for news. Then there came a wild report of his murder, and staunch old Sir Roderick sent out an expedition, under Mr. Young, to Lake Nyassa, which successfully performed its mission, and gave us the assurance that the report was false and that Livingstone was alive. All this while the great traveller was toiling steadily at his appointed task, and had completed the solution of one great geographical question, namely, that of the northern limits of the basin of the Zambesi river. Another long period elapsed, and once more a letter was received from Ujiji, on the banks of Lake Tanganyika, announcing the progress of the work. Having cleared up the problems relating to Lake Nyassa, Livingstone had ascended highlands which form the water-parting between the Zambesi and another great system of rivers and lakes to the north. He had been in a land where the vegetation was saturated with moisture—a land unlike all previously-conceived ideas of this part of Africa. The work was beginning to tell upon him. He described himself as a mere "bag of bones." But he gave no sign of faltering in his purpose. His great discovery was not half achieved, and the time for rest was still distant. His will was unsubdued; his life-work must be completed before he could turn aside to be refreshed; and thus he disappeared again.

Years passed away—first one, then another and another, and for a third time the anxiety of the country began to increase. For Britain still cares for and watches over her great sons. The indomitable yet unostentatious resolution of this grand old man has touched the heart of the nation to its very core. Sir Roderick Murchison died in the full hope and expectation of soon receiving tidings of his friend. No truer nor more steadfast friend ever lived; and the news of Sir Roderick's death will be the saddest words that Livingstone has heard since he lost his brave wife in the wilds of the Zambesi. Then it began to be felt that it would be wrong to wait longer. Our patience was exhausted; an appeal was made to the country which was warmly and munificently answered; Lieut. Dawson left this country in command of a search expedition, reached Zanzibar, and proceeded without delay to make preparations for his march into the interior.

The rest of the story must be gathered from the telegrams which have arrived from Bombay and Aden within the present week. News, it seems, came down to Zanzibar last May that Livingstone was alive, that he had reached Kazeh, on the road between Lake Tanganyika and the coast; but that he declined to return home until his work was completed. In those years of enforced silence, during which his letters had been intercepted by Arab slave traders, he had been working hard. He had completed one more great discovery; but still the work was not all done, and he would not come home. All honour to this man of iron will and unchanging purpose!

The second great discovery of Livingstone, since he landed at the mouth of the Rovuma, is more important, if possible, than the first. His first discovery was the north-eastern water-parting of the Zambesi. His second, the tidings of which arrived by telegram last week, is the limits of the great basin of Lake Tanganyika, and that a vast and separate system intervened between the basins of the Nile and the Zambesi. The discovery of the basin of Tanganyika, extending from about 3° to 10° S. latitude, and 27° to 39° E. longitude (or 700 miles long by about 450) is the last and not the least important of Livingstone's discoveries. It would appear, from the telegram, that the great explorer traced the chain of lakes and the streams which flow from them, until he discovered that all the waters found their outlet in the Tanganyika. He then, it would appear, visited the northern end of the lake, and found that the rivers still flowed into it. The waters of the lake are fresh; and it is, therefore, to be inferred that the lake has an outlet. Livingstone now knows the southern, western, northern, and north-eastern sides of the lake. The south-eastern side alone remains to be explored, and there, if anywhere, the great outlet for its waters must be. That outlet must be discovered and examined before Livingstone's great achievement is ended; and thither, therefore, he will now proceed.

We already have some knowledge of the river which, as it would now seem, flows from Lake Tanganyika to the sea. Mr. Desborough Cooley, in 1841, gave the information obtained from an intelligent Sawahili named Khamis bin Othman, who came to London in 1835. This man had travelled up the ravine of a river named Lufiji, from its mouth due west of the island of Monfia (south of Zanzibar) to its source in the lake. Nearly half a century ago, when Captain Owen was making a running survey of part of the East Coast of Africa, he was off the mouths of this river Lufiji, and they are shown on his chart, published in 1825, though Mr. Cooley and Captain Burton appear to have overlooked them. But Captain Burton, in his exhaustive paper on these lake regions, has shown that the Lufiji is the same river as the Rua or Ruaha, though he says that the source is unknown. It will be found on the maps to the east of the south end of Lake Tanganyika. It must not be confused with another Rua, mentioned by Livingstone to the west of Lake Tanganyika, and north of the Lake Moero. The sentence in Lieut. Dawson's telegram, "Underground village next attracts Livingstone's attention," has, perhaps, been satisfactorily explained by Colonel Grant. He gathered, from the intelligence he and Captain Speke obtained in the country, that the waters of the Tanganyika force their way through a rent in the mountains, at the south-eastern extremity of the lake,

and that under the river there is a natural tunnel. This tunnel was described to Colonel Grant as being two months' march from Unyanyembeh, and as a tunnel made by God, which takes a caravan from sunrise to noon to march through it. An unfordable river, with rocky cliffed sides, flows over the tunnel at right angles with Lake Tanganyika. This river is now supposed, on apparently good grounds, to be the Ruaha of Burton, and the Lufiji whose mouths are shown on Captain Owen's chart.

We now learn that Livingstone has reached Unyanyembeh, that stores are being sent up to him as rapidly as possible in charge of his son, and that he will march southward to explore this Ruaha or Lufiji river, this mighty outlet of the great system of waters that he has discovered, with its lofty cliffs and alleged natural tunnel. Thus, for the third time, all fears have been dispelled, again we get a glimpse of this true knight-errant, and again we find him stedfastly working at the task he set himself to do six years ago, and which he will not abandon until it is finished. This last section of his labours will comprise the complete discovery of the great basin of the Tanganyika, including the collection of accurate information respecting its limits, its varied climates, its productions and capabilities and people, its rivers and lakes, and its outlet to the Indian Ocean. The addition to geographical knowledge will be enormous, and we may well hope that this knowledge will be the means by which a new country will hereafter be opened to European enterprise, and the object of Livingstone's life be attained. If he dies in the midst of his discoveries he may well be envied, for a nobler and more glorious end can hardly be imagined. If, as we all hope and as is more likely, he is spared to return home, and perhaps to watch in his old age the progress of the mighty work which he is now initiating, he will receive a welcome from his countrymen such as few have experienced and fewer still have so justly earned.

CONVERSATIONS ON NATURAL PHILOSOPHY

Conversations on Natural Philosophy. By Mrs. Marcet author of "Conversations on Chemistry," &c. Revised and Edited by Francis Marcet, F.R.S. 14th Edition. (Longmans, 1872.)

WE opened this new and revised edition of Mrs. Marcet's "Conversations on Natural Philosophy" with expectation and interest; we closed it with disappointment and regret. The influence Mrs. Marcet exerted upon the early career of Faraday, besides awakening the first love for science in hundreds of the last generation, will cause her name always to be remembered with gratitude and respect. Science, however, has made great strides since Mrs. Marcet wrote; and if her admirable works are touched at all, they should, where necessary, be carefully and accurately revised. That this has not been done in the book before us we will briefly point out. Opening at the Conversation on Heat, we read the following statement on p. 207:—"It is because heat, light, and electricity are not subject to the general properties of other bodies, and in particular to that of gravity, that they are commonly known by the name of imponderable fluids;" and on the next page we read "that modern chemists having adopted the new word *caloric*, to denote the principle that produces heat," we are told that "caloric is found to exist in a variety of forms or modifications; and we shall consider it under the two following heads, viz.: 1. Free or radiant caloric. 2. Combined caloric. The first free or radiant caloric is also called heat of temperature," &c. Again further on, p. 250, the same instructor says, "the two principal solvent fluids are *water* and *caloric*;" leading thereupon to a lively conversation as to how caloric dissolves bodies. This, we are told, is the way:—"Caloric, we may conceive, dissolves water, and converts it into elastic vapour by a process similar to that by which water dissolves salt. . . . . It is now ascertained that the solvent power of the atmosphere depends solely upon the caloric contained in it"! Vivid pictures of caloric are given, as "a fluid so extremely subtle that it enters and pervades all bodies whatever, and forces itself between their particles;" in similar language specific heat is defined, on p. 275, as "that which is employed in fitting the capacity of a body for caloric, in the state in which that body actually exists." Thus the minds of young children for whom this book is intended are drilled into the needless and obsolete jargon of the material theory of heat.

Even the most elementary facts are often left wrongly explained. Thus, on p. 255, the formation of hoar frost is accounted for in this way:—"The freezing of the watery vapour, which the atmospheric heat could not dissolve, produces what is called a hoar frost; for the particles descend in freezing and attach themselves to whatever they meet with on the surface of the earth." We venture to think there are few intelligent unscientific people who could not correct this.

We have dwelt thus far on the subject of heat, for here it is that new editions of once famous books need most revision. But glaring errors are to be found in other parts. The diagram representing the shadow which a large luminous body casts behind a small opaque body (Plate 21, Fig. 3), is incorrectly shown, the converging umbra only being represented without the accompanying diverging penumbra. On p. 313 the luminiferous ether and water are spoken of as inelastic bodies. The absence of a sound shadow in air is affirmed on the same page, whereas among other instances every one must have noticed when watching the approach of a distant railway train, how, as it winds along and is occasionally hidden from view, corresponding sound shadows flit across the ear.

We have only space to indicate a few more blunders that catch our eye. In voltaic electricity the electric light does *not* "dart from one point of charcoal to another," as soon as the points are brought from "half an inch to an inch" asunder. The thickness of a silk handkerchief (as the writer has tried with a battery of nearly 200 cells) will prevent the discharge taking place before contact is made. The term "conjunctive wire," p. 428, was used by Oersted, but is not now used to express the wires which join the poles of a battery. In the electric telegraph the current does *not* return through the earth to the battery whence it came. This is a very popular error.

We regret to be obliged to call attention to these serious defects in what might have been made a useful book. We still more regret to think that this volume, owing to Mrs. Marcet's excellent name, will find its way into families and schools; many will thus gain their only knowledge of science from a volume which contains not only many obsolete phrases, but which also omits all reference to the conservation of energy or the correlation of the physical forces. W. F. B.

THE GEOLOGICAL SURVEY OF OHIO

Geological Survey of Ohio. Report of Progress in 1870, by J. S. Newberry, Chief Geologist, including Reports by the Assistant Geologists, Chemists, and Local Assistants. (Columbus: Nevin and Myers, State Printers, 1871, pp. 568.)

THE labours of Prof. Newberry and his colleagues during the year 1870 have resulted in the accumulation of a great many details relating chiefly to the structure of that portion of the great Appalachian Coal-field which extends over a considerable part of Ohio. Without the aid of a good map it is somewhat difficult to follow the descriptions given in this Report, the numerous local references and details having a tendency to bewilder the reader. This, however, is unavoidable under the circumstances; and those who desire to obtain a full and clear conception of the geological structure of Ohio will have to wait the completion of the map and final report promised by Dr. Newberry, the present volume not pretending to be more than its title implies. Nevertheless, it contains a very large and varied amount of information, which will, no doubt, be duly appreciated by those for whom it has been prepared. Especially noteworthy are the numerous illustrative sections of Carboniferous strata, and analyses of coals, ironstones, fireclays, and soils, as also two ably written sketches "On the Present State of the Manufacture of Iron in Great Britain," and "On the State of the Steel Industry," both of which will repay perusal by those of us here who are interested in these matters.

Scattered through the purely geological portion of the Report are many points of interest, which arrest attention as one glances over the pages. Thus we are told that "at Zaleski, in mining the Nelsonville coal, a fine boulder of grey quartzite was found half imbedded in the coal, and the other half in the overlying shale. The quartzite is very hard, and the boulder was rounded and worn by friction before it came to the coal." It measured 17 in. by 12 in., and had adhering to it in places bits of coal and black slate which showed a slickensided surface. The stone appeared to have settled into the coal when the latter was in a soft state. Prof. Newberry speculates with diffidence on the possibility of the boulder having been "brought down by river ice from some higher and colder part of the old continent, which was skirted by the coal-producing lowlands." In connection with this it is somewhat interesting to find that a local deposit of quartz conglomerate occurs here and there underneath and skirting the coal-strata, and is believed by Dr. Newberry to represent an old beach of the period. From some such gravel and shingle deposit the boulder may have been transported, but whether by means of ice, water-plant, or land-plant, who shall tell?

Another exceedingly interesting and readable portion of the Report is the "Agricultural Survey," by Mr. J. H. Klippart, in which the writer discusses, amongst other subjects (such as prairies, forests, &c.), the origin of the soils in certain districts of the State. Those geologists who believe in the former existence during the Glacial epoch of mild interglacial periods will find much here to support their opinion. We are told that the succession of the Drift materials, beginning with the oldest, is as follows:—

a Glacial drift.
b Erie clays.
c Forest bed.
d Iceberg drift.
e Alluvium.
f Peat, calcareous tufa, shell marl.

The oldest deposit is believed to be the product of land-ice, and the presence of the Erie clays betokens that after the disappearance of the great glaciers, wide sheets of fresh-water overspread some districts of the State. The forest bed (consisting of roots, trunks, branches, and leaves of such trees as sycamore, beech, hickory, and red cedar) shows that by-and-by the fresh-water basins were in some places filled up, and the new soil covered with an abundant forest-growth. After this came a period of depression, when great deposits of gravel and sand gathered over the surface of the drowned land, and large boulders and erratics were floated by ice from the north.

These and other matters of interest and importance will, no doubt, be fully treated of in the final report, which is to consist of four volumes, the first two being devoted to the geology and palæontology of the State, the third to its economic geology, and the fourth to its agriculture, botany, and zoology. A large collection of fossils has been made, many species being new to science. It is to be hoped that the good people of Ohio will not grudge the money that will be required for the adequate representation and description of these remains, but that when published the final report will be found in every way as complete as those admirable works which have been issued by other States of the Union. Professor Newberry seems to have little doubt that it will be so, for he thinks that the value and significance of fossils are coming to be generally appreciated. "There are, however," he says, "yet some intelligent men, even editors and members of legislature, who cherish the notion that there is nothing which has any value in this world but that thing which has a dollar in it, and that so plainly visible as to be seen by them. Such men, to quote the language of one of them, 'don't care a row of pins for your clams and salamanders, but want something practical.'" This "practical" man must surely have been related to that colonial official who is said to have objected strongly to the expense of "engraved portraits of extinct bugs and beetles," as he irreverently styled certain Silurian fossils. But the day of such wiseacres has gone past, and it may be confidently expected that Dr. Newberry and his colleagues will have no difficulty in getting the necessary funds voted for the completion of their important Survey. J. G.

OUR BOOK SHELF

Meibauer's Physische Beschaffenheit des Sonnensystems. (Berlin: Carl Habel.)

THIS is a second and freshly-arranged edition of a comprehensive little treatise on the nature of the solar system. It requires no great acquaintance with the present state of science to vindicate the accuracy of the author's preliminary remark, as to the difficulty that students experience from the wide dispersion of modern observations among heterogeneous memoirs and journals in various languages, and the necessity of a large library and abundance of leisure; and it is impossible not to appreciate his attempt to combine these scattered materials in a condensed and accessible form. Nor can it be doubted that a considerable amount of labour has been devoted to the work, which has been made attractive by perspicuity of treatment and facility of style, as well as by occasional ingenuity in hypothesis. Yet the execution cannot be said to correspond with the excellency of the design; and the deficiency, more apparent perhaps to our own minds than to those of Continental readers, is such as necessarily results from one-sided and imperfect views. The eternity of matter, an idea to many minds especially and utterly abhorrent, should not, to say the least of it, have been assumed; and other less objectionable hypotheses and statements are adopted, which may not be as incontrovertible as unwary readers will be led to suppose. No doubt the author, in employing as part of his motto the words of Darwin, "False facts are highly injurious to the cause of science," was quite unconscious that the result of an inquiry into some of his own facts (or rather assertions) would not be quite satisfactory. But we do not know what to make of such statements as these—that Priestley called his vital air (oxygen) by the name of Phlogiston—that Huggins found in the nuclei of comets the lines of nitrogen, hydrogen, and carbon similar to those given by the Geissler tubes—that there are two bright lines in the spectrum of Sirius, one of which is displaced by the star's movement—that the red, green, and yellow tints of the aurora never lose their relative positions; that the force of gravity at the upper limit of the atmosphere may be considered not materially different from that on the earth's surface, while the centrifugal (tangential) force perceptibly increases. Nothing but an unkind, or bitter, or self-ignorant spirit would refuse to leave a fairly broad margin for inevitable human imperfection; but it must be a very large paper copy indeed that would find room for statements such as these. Nor is it easy to understand why Lockyer's just claim should have been ignored to an equal share with Janssen in the grand discovery of prominences round the uneclipsed sun; or why discredit should have been thrown upon the connection of the solar-spot maximum with Sabine's magnetic period, or the planetary one established by the Kew observers. Other omissions might be pointed out, and the work would have been greatly improved by a discussion of the effects of temperature and pressure in modifying elementary spectra—a branch of inquiry to which allusion has barely been made, but which is of essential importance in spectrum analysis, and the fuller development of which alone, perhaps, promises a more satisfactory solution of many cosmical phenomena. But while it appeared a matter of duty to mention these deficiencies, we must add, in all fairness, and with greater pleasure, that some of his theories are very interesting and well handled; such as that in which he would account for the eruption of the protuberances by the unstable condition of gaseous matter on the confines of fluidity, discovered by Andrews and Thomson; or that of the unlimited extension through space of the planetary atmospheres in extreme tenuity; and there is much ingenuity, at any rate, in the idea of accounting for the variations of atmospheric pressure and electricity between the tropics by the resistance, however infinitesimal, which our globe sustains in its rapid passage through a space to which neither Newton nor Laplace ascribed absolute vacuity. The curious inconsistency with which, as a denier of equivocal generation, he calls in the germs of terrestrial vegetation from external space, where they have been educed under certain conditions of temperature, pressure, and time, is but a specimen of the difficulties to which every hypothesis is subject, that ignores the existence of an omnipotent will; but there are some who will look with amusement, and some few with a warmer feeling, at his vigorous onslaught on the idea of a luminiferous æther; concluding with the keen remark, that to prove the existence of such an æther, recourse is had in turn to the very phenomena which it was invented to explain.

Knapsack Manual for Sportsmen on the Field. By Edwin Ward. (Bradbury and Evans, 1872.)

ONE who has come so much in contact with sportsmen as Mr. Ward must have done should surely know that men do not go out with knapsacks when intent on killing big game. The title "Knapsack Manual" is most unfortunate. Moreover, if the book is intended for sportsmen *on* the field, why should a considerable portion of it be given up to the mode of setting up a tiger, which a sportsman is very unlikely to do for himself, and certainly would not attempt in the field? Mr. Ward, though he seems to have considerable regard for artistic treatment and compatibility in the setting up of skins, would yet appear to put lichens with his stuffed birds in the conventional style. What a relief to the eye it would be to see a case of stuffed birds without a particle of dead wood or lichens in it! The directions given for skinning and preserving specimens are not full enough; there are better works on the subject in existence. The lists of game to be found in various parts of the world, at the commencement, form the most useful part of the book. The account of a Museum of Natural History of the Earth from man to a granite stone contained in a case 10 ft. long by 7 ft. high, displays a lamentable amount of ignorance. Some of the remarks about the various creatures are very amusing, as, "Gasteropoda proceed by the belly." "Armadillos are very remarkably swift in flight." Altogether this book appears to be of the nature of an advertisement, and we think a not very successful one.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Method of Least Squares

IN the number of NATURE for June 6, Prof. Asaph Hall, of Washington Observatory, called attention to what he regards as a singular oversight in the history of this subject, viz., that in 1770-1773 Lagrange published an elaborate memoir at Turin under the title "Mémoire sur l'utilité de la Méthode de prendre le Milieu entre les résultats de plusieurs Observations, &c." Prof. Hall remarks that the only notice of this memoir he has seen is contained in the *Berliner Jahrbuch* for 1853, and that in the abstract of a memoir of mine on the subject in the notices of the Royal Astronomical Society for April 1872, the name of Lagrange does not appear.

As regards myself, I need only state that Lagrange's memoir, as well as Simpson's, is referred to in my paper; although, as no examination is made of it there, the name is omitted in the Abstract, where reference is only made to the authors of investigations in which an attempt is made to prove either the law of facility or the method of least squares, and which were therefore referred to with more or less detail in the paper itself.

Further, I should not regard it as an omission if in the history of Least Squares no mention was made of Lagrange; in fact,

when I was examining all the investigations I could find on the subject, after looking through Lagrange's memoir (and reading carefully Todhunter's *résumé* of it), I came to the conclusion that it contained nothing that could, properly speaking, be regarded as an anticipation of the later investigations of Gauss, Laplace, &c., and I contented myself therefore with merely a passing reference.

Lagrange's paper, as its title implies, gives a mathematical justification of the choice of the mean of a series of discordant observations, and a determination of the chance that the resulting error lies between certain limits, with developments, &c.; but the method of Least Squares may be described as an extension of the principle of the arithmetic mean to the combination of linear equations, involving more than one unknown; the problem being to obtain the best values of the unknowns from a series of discordant *linear simultaneous equations*.

The method of Least Squares was first proposed in print by Legendre in his "Orbites des Comètes" (Paris, 1805), as a convenient way of treating observations without reference to the Theory of Chance. Legendre's words are "la méthode qui me paroît la plus simple et la plus générale, consiste à rendre minimum la somme des quarrés des erreurs . . . et que j'appelle Méthode des moindres quarrés. The method, regarded from a practical point of view, is a very natural one; we shall clearly get a good result by determining the quantities to be found so as to make the sum of the $2n$th powers of the errors a minimum, and in order that the resulting equations may be linear (and therefore manageable), we must take n equal to unity.

Though first published by Legendre, the rule was applied by Gauss, as he himself states, as early as 1795, and the method is explained and the usual law of facility for the first time found in the "Theoria Motus Corporum Cœlestium, Hamburgh, 1809 (not 1808, as in Prof. Hall's letter). The principle on which Gauss proceeds may fairly, I think, be stated as follows:—If there are given a number of discordant observations V_1, V_2, &c., of a quantity x, so that we have the equations $x - V_1 = o$, $x - V_2 = o$, &c., then it is known that a very good result is obtained by giving to x the arithmetic mean of its observed values, and writing $x = \frac{1}{n}(V + \ldots + V_n)$; and it is required to find an equally good rule for determining x, y, z, &c., from a number of discordant equations of the form $a_1x + b_1y + c_1z + \ldots = V_1$, $a_2x + b_2y + c_2z + \ldots = V_2$, &c. Assume therefore that $x = \frac{1}{n}(V_1 + \ldots V_n)$ is the most probable value of x derived from the first system of equations, and find the law of facility of error that this may be the case; then, having this law, the most probable values of x, y, z, &c., can be found for the second system.

The law of facility Gauss finds to be represented by $\frac{h}{\sqrt{\pi}} e^{-h^2x^2}dx$, viz., this is the chance of an error of magnitude intermediate to x and $x + dx$; and thence it follows that the most probable values of x, y, z, &c., are found by making $(a_1x + b_1y + c_1z + \ldots - V_1)^2 + (a_2x + b_2y + c_2z + \ldots - V_2)^2 +$, &c., a minimum. Gauss then proceeds to determine h in the manner still generally adopted.

Subsequent writers, Laplace, Poisson, &c., have in consequence investigated how far the arithmetic mean is the most probable result, &c., and in one sense Lagrange (and *a fortiori* Simpson) may be said to have very slightly anticipated a portion of the analysis required in these researches, although, as far as the method of Least Squares is concerned, there is no anticipation. A slight examination will show how greatly superior Laplace's analysis is to Lagrange's on the same subject.

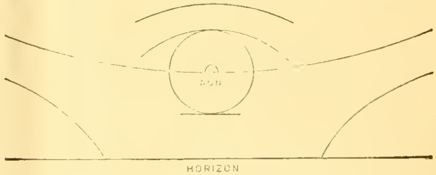
With reference to the independent discovery of the method of Least Squares by Dr. Adrain of New Brunswick, U.S. (see Prof. Abbe's note in the *American Journal of Science*, June 1871), I may remark that if for distinction we call the introduction of the merely practical use of the rule its "invention," and its philosophical deduction by the Theory of Probabilities its "discovery" (so that Legendre invented the method and Gauss discovered it), then Dr. Adrain can only be credited with the independent invention of the rule, viz., he only did what Legendre had done two years previously. This is worth noticing, as from the occurence of the function e^{-x^2} in Dr. Adrain's paper, it might be supposed that it contained some anticipation of Gauss' investigation; but such is not the case, and Dr. Adrain's reasons for the adoption of the law are of so trivial a nature that it is incredible that any mathematician should have been led to the discovery of the method by means of them. I imagine that he had noticed the practical convenience of the rule, and subsequently endeavoured to justify it analytically; it may be noted that it is possible that Dr. Adrain may have seen or heard of Legendre's memoir published two years before; his silence on the matter, however, renders it unlikely that this was so. On the whole, by far the greater part of the merit of the introduction of the method is due to Gauss; while the credit of the first suggestion of the practical rule must be assigned to Legendre, Dr. Adrain having, in all probability independently, also suggested the same rule subsequently. It is necessary to be thus particular, as Gauss' publication having taken place in 1809 and Adrain's in 1808, it might be thought that the latter had anticipated the former to some extent, which is in no wise the case.

In writing the history of the Theory of Errors or the Theory of the Treatment of Observations, there are several memoirs anterior to Legendre's that would have to be included, and notably Thomas Simpson's "Miscellaneous Tracts," 1757 (which is the work Prof. Hall doubtless refers to), Daniel Bernoulli's "Dijudicatio maxime probabilis plurium observationum discrepantium," &c. Acta. Petrop. 1777, Trembley's paper in the "Berlin Memoirs," 1801, "Observations sur la méthode de prendre le milieu entre les observations," &c. For the above references I was indebted to Todhunter's "History of the Mathematical Theory of Probability from the time of Pascal to that of Laplace" (London, 1865), which contains a notice of every work or memoir on the subject to the commencement of the present century (there is a *résumé* of Lagrange's memoir occupying 13 pages), so that no one need have any fear of passing over any writings published previously to 1800. Having had occasion to make much use of the work, I may be permitted to say that its value, both as regards accuracy and completeness, cannot be over-estimated. J. W. L. GLAISHER

Trinity College, Cambridge, June 8

Solar Halos

A BEAUTIFUL combination of solar halos was visible here during the morning of March 2. At 10·45 the sun having an altitude of about 40° was surrounded by a complete rainbow-tinted circle of some 18° or 20° radius, red inside and blue outside. An arc of a larger circle coloured in the same way touched the complete circle at its highest point, rendering the point of contact dazzlingly bright. A short arc touched the lowest point



of the circle in the same manner. A white halo passed through the sun's position parallel to the horizon, and two fainter white arcs intersected it obliquely in the point opposite to the sun, forming a conspicuous sun-dog. There were also two rainbow-arcs having their convexities toward the sun. These were blue inside and red outside, and their centres appeared to be about 90° from the sun, and some 15° below the horizon. Later an arc concentric with that touching the complete circle appeared above it, having the colours reversed, namely, blue inside and red outside. These appearances lasted about an hour and a half before beginning to fade away. W. W. J.

Gambier, Ohio, March 5

The Volcanoes of Central France

THE Auvergne volcanoes threaten to be as periodic a subject of controversy as the authorship of the letters of Junius. It is only seven years since the last eruption of letters. At that time I contributed a paper to the *Geological Magazine* (vol. ii. p. 241), in which I collected, printed, and translated all that I could find on the subject, and came to the conclusion that it was very probable there had been some local outbreak of volcanic action. Thus I agree with Mr. Garbett, but it appears to me that he has not

made his case in one respect so strong as it might be. In the passage "nunc ignes sæpe flammati *caducas culminum cristas* superjecto favillarum monte tumulabant" (as the edition which I follow has it) he translates *culmina* "roofs," and again in the parallel passage of Avitus. I think it more likely to mean summits (of mountains), and to refer to the formation of one or more new cones in the hill country.

My reason for this may be given in the words which I used in the paper above named—"though Sidonius is inclined to bombast, he scarcely seems equal to a flight like this. . . . In the parallel passage in Avitus, the reference to Isaiah ii. 10, 19, 21, and Luke xxiii. 30 appears too clear to allow any other meaning than mountain-top to be assigned to *culmen*." To this I may add that the ridge-roofs, *cristæ culminum*, would be those least likely to be broken by a shower of ashes, and the ridges would be the part where the smallest quantity of ashes would rest.

T. G. BONNEY

St. John's College, Cambridge

Force and Energy

REFERRING to Mr. Brooke's article in NATURE of the 13th on Force and Energy, I would suggest that though it is quite true that heat is a "mode of motion," this is probably not true of magnetism and static electricity. Heat is molecular *motion*, magnetism and static electricity are molecular *tensions*.

I would also remark that the term "radiant heat" ought to be discarded as misleading. Radiant heat is not a kind of heat; it is quite distinct from heat, but it is nearly identical with light. We ought to introduce the word *radiance*, and then we get to this statement:—All rays of radiance have more or less heating power, and some of them have also the power of producing the sensation of light. But the fact that only some rays, and not those which have the most heating power, produce the sensation of light, belongs rather to the retina than to the rays.

Mr. Brooke thinks the proposition that the sum total of energy in the universe is unchangeable is incapable of proof. I do not speak as having any authority, but it seems to me that if this is not true the conservation of energy cannot be universally true.

JOSEPH JOHN MURPHY

Pelagic Fish-Nest

SEEING an extract from NATURE with reference to the nest of the pelagic fish, allow me to inform you of the discovery of what I presume to be a similar nest in lat. 25° N., long. 65° W., whilst on a voyage between Buenos Ayres and New York last January. I had improvised a drag-net out of a barrel hoop and a biscuit bag, to fish up for examination the straw-coloured floating gulf-weed, which covered the sea in long lines and patches between 20° and 32° N. lat.; and one day there came up in the net a mass of weed compactly woven by strong, white, silky fibres into a round ball of about ten inches in circumference. The surface of this ball was covered with a network of these fibres, to which large numbers of glassy eggs, about the size of partridge shot, were attached. The eggs were transparent, and their cases very tough. The only living inhabitants of the ball were one or two small shrimps and a small crab, who was carrying his own particular egg-sac.

Another curious fact I am tempted to mention. About 200 miles from Cape Frio, the sailors caught a dolphin, which had in its stomach twenty pieces of coal, varying from a large walnut to a marble in size, together with the heads of four iron nails about an inch in length each. I am tolerably certain that these articles had not been thrown from our vessel, but they did not appear affected by the internal wear and tear, however long they might have been digesting.

Why are Red Sandstones Red?

I HAVE lately been interested in the reply to this question given by Prof. Ramsay, and stated by Prof. Geikie in his recent edition of "Jukes's Manual of Geology" (pp. 567, 568). But the explanation, viz., that the red colour is derived from the precipitation of red (consequently anhydrous) peroxide of iron in inland seas, appears to me to give rise to this other question—Why should the precipitated peroxide be anhydrous, and not hydrous and brown, as is the case with limonite, which is found deposited in marshes, ponds, and lakes?

I have tried some experiments in precipitating the peroxide of iron from a solution made as saturated as possible by long boiling of water or oxide of iron (obtained from a natural spring), common salt, and finely divided sulphate of lime (these last two minerals being found to accompany the red rocks), filtering hot, and allowing to stand till cold. For want of experience in these matters, probably, I have not yet succeeded in obtaining any red colour.

I have, however, to-day fallen on a paper describing a similar experiment to account for the presence of anhydrite in the Stassfurt mines. In this case it is stated that the *anhydrous* sulphate of lime was obtained on evaporating a concentrated solution of gypsum and rock salt.

I should be glad to learn whether the attention of any of your readers has been drawn to this question, and whether they have succeeded in obtaining (under conditions analogous to those of an evaporating inland sea) a precipitation of the red colouring matter.

A YOUNG GEOLOGIST

Mounting of Thermometers

I HAVE experienced precisely the same inconvenience as that mentioned by Mr. Whipple in NATURE last week.

I several times removed the outside case of a thermometer such as he describes, and took every precaution to dry the air before replacing the packing, but the moisture in the tube persistently reappeared. It then occurred to me that the amount of moisture was out of all proportion to the quantity of air confined, and that the mischief arose from the packing not being air-tight; and fresh damp air was thus continually finding its way into the tube, and depositing moisture. Accordingly the tube was again removed, and after drying carefully, I replaced it, and pushed in the india-rubber packing about an eighth of an inch. The intervening space was filled up with common putty, which was made to assume a conical form round the thermometer stem. After being left for a day or two to harden, the putty was painted over with two or three coats of sealing-wax dissolved in alcohol. This thermometer has been constantly exposed on the grass for about four months, and though I purposely took no means to dry the air in the case, not the slightest inconvenience from a deposition of moisture has since been experienced.

A Few Millions

IN your reprint of Prof. Mayer's paper, entitled "Acoustical Experiments" in NATURE for May 9, 1872, there occur some strange numerical errors, which perhaps it will be well to point out, lest some of your readers should make use of the numbers given at the end of the paper without previously testing them. After describing his experiments, he proceeds:—"We will now examine the analogical phenomena in the case of light:—Let fork No. 1, giving 256 vibrations a second, stand for 595 millions of millions vibrations a second, which we will take as the number of vibrations made by the ray D_1 of the spectrum." Taking the velocity of light as 185,300 miles per second, and the wave-length of D_1, as given by Angström, at 0·00058950 millimetres, gives 5,058,700,000,000,000 vibrations per second, or a little more than five thousand millions of millions, instead of a little less than six hundred millions of millions vibrations per second, as given by Dr. Mayer. But to proceed—"Then fork No. 3 will represent 590 millions of millions vibration per second," this should be 594 millions of millions vibrations, "which give a wave-length ·0000042 millimetres longer than D_1." This again is not quite right, even according to Dr. Mayer's own showing; it should be ·00000495 of a millimetre longer than D_1. Dr. Mayer then goes on to say that such a wave-length nearly corresponds with an iron line situate ·42 div. below D_1 on Angström's chart; and "we saw that fork No. 3, giving 254 vibrations a second, had to move toward the ear with a velocity of 8·734ft., to give the note produced by 256 vibrations per second emanating from a fixed point; so a star sending forth the ray which vibrates 590 millions of millions a second will have to move toward the eye with a velocity of 28,470 miles per second to give the colour produced when ray D_1 emanates from a stationary flame." This again, according to Dr. Mayer's own method, should be 1,557 miles, or less than a nineteenth of the velocity given by him.

Instead of involving ourselves in millions of millions, and the translation of millimetres into English miles, it seems simpler to avoid the calculation of the number of vibrations per second, and to get at the required velocity by a simple rule-of-three sum, thus: As the emitted wave length is to the difference between the observed

wave-length and the emitted wave-length, so is the velocity of light to the required velocity, to or from the observer.

A. Cowper Ranyard

PROF. CANNIZZARO'S FARADAY LECTURE

THIS lecture was delivered on May 30, by Prof. Cannizzaro. The lectureship was founded by the Chemical Society in honour of the illustrious Faraday, to be held by some eminent foreign *savant*, who, during the term of his tenure is to deliver a discourse before the Society. Dr. Frankland, in introducing the lecturer, said that in 1869, M. Dumas had honoured them with his presence there, and on that night they were to listen to Prof. Cannizzaro, of Palermo. After alluding to the numerous investigations which the Professor had made in organic chemistry, and amongst others the discovery of benzylic alcohol, the first normal aromatic alcohol that had ever been prepared, and to the important theoretical views which he had originated, the President, in the name of the Society, presented to him the Faraday Medal, struck in honour of his visit.

Prof. Cannizzaro said that when he received the flattering invitation to deliver the Faraday Lecture, he was placed in very unfavourable circumstances to respond to it, as he had no definite results to lay before the Society, and was, moreover, on the point of suspending his labours and abandoning his old laboratory in order to remove to Rome, and establish a new one there. In this difficulty a subject for a discourse fortunately presented itself, one which the celebrated French chemist, Dumas, had promised to treat of in 1847, namely, the form which the theory of chemistry should take at the present time. Although this could not be fully discussed in so short a space of time, it would at least have the advantage of directing the attention of chemists to a question of great importance in the transition stage which our science is at present going through.

In recalling the promise which M. Dumas had made to the Academy of Sciences of Paris in 1847, to examine the form which theoretical instruction in chemistry should take in the present state of the science, the lecturer proposed to consider in his discourse the limits within which the exposition of general theories should be included in teaching chemistry, and the form that it was desirable that they should assume. Whilst giving a broad sketch of the progress of modern chemistry, he showed that the atomic theory had become more and more intimately interlaced with the fabric of chemistry, so that it is no longer possible to separate them without rending the tissue, as it were, of the science; and that up to the present time we have been unable to enunciate even the empirical laws of chemical proportion, independently of that theory; for those who employ the term equivalent in the sense that Wollaston did, commit an anachronism. Consequently, in the exposition of the value and use of symbols, formulæ, and chemical equations, not only are we unable to do without the atomic and molecular theory, but it is inconvenient to follow the long and fatiguing path of induction which leads up to it. By one of those bold flights of the human mind we can at once reach the height whence we discern at a glance the relations between facts.

He then went on to show that the solid basis, the corner-stone of the modern molecular and atomic theory, the crown of the edifice of which Dalton laid the foundation—is the theory of Avogadro and Ampére, Koenig and Clausius, on the constitution of perfect gases, to which chemists, unknown to themselves, have been led in the progress of their science. He thought the time had arrived for reversing the order which had hitherto been followed in teaching chemistry, that instead of setting out from the criteria for determining the weight of molecules, and then showing their ratio to the vapour densities, they ought, on the contrary, to commence with the latter, with the theory of Avogadro and Clausius, demonstrating it from physical considerations; to found upon that the proof of the divisibility of simple bodies, that is to say, the existence of atoms; and to show, as occasion presented itself, that the weights of the molecules and the number of the atoms deduced by the application of this theory, are in accordance with those which are deduced from chemical criteria. By this means we can measure the degree of confidence to be placed in the latter criteria; since so-called compound equivalents do not suffice to determine the weight of molecules, or even to prove their existence, although they may be deduced from a single principle, the theory of the constitution of gases. This is the natural transition from physics to chemistry.

The Professor then stated in detail how he applied the principles he had laid before them. He introduced his pupils to the study of chemistry, by endeavouring to place them on the same level as the contemporaries of Lavoisier, and to teach them to appreciate the importance of the principle of the conservation of the weight of matter, showing them that this is quite independent of any idea of its nature or constitution. They are thus led to examine the ponderable composition of substances, so that the student passes rapidly from the epoch of Lavoisier to that of Proust, and then to that of Berzelius at the time when he commenced his researches on proportions. At this stage the same impulse is given to the pupil as Berzelius received on becoming acquainted with the hypothesis of Dalton. The latter is laid before him without any accessory, the use of symbols and formulæ being introduced dogmatically. There will now arise in his mind the same doubts and difficulties that assailed Berthollet, Sir Humphrey Davy, and Wollaston in the application of Dalton's theory, and at the same time a desire for an explanation of the simple relation which exists between the vapour volumes of bodies which react on one another and of the products which are obtained. Now is the moment to state or recall to mind the physical theory of the constitution of the perfect gases. Commencing with a rapid glance at their general and special characters he insisted, that in this part of the instruction the mind of the student should not be diverted from the numbers expressing their relations, by considerations of the variations caused by changes of temperature and pressure. In applying the theory of the constitution of gases, it will be perceived that the molecules of simple bodies are not always the atoms of Dalton, and a certain confusion will thus be produced in the mind of the beginner in the conception of the ideas of atoms and molecules. The hypothesis of Dalton can now be laid aside, substituting as a starting-point the theory of the relation of molecular weights to the vapour densities. A table must be prepared of the vapour density compared with that of hydrogen as 2, that is to say, the weights of their molecules compared with the weight of the semi-molecule of hydrogen taken as unity. We must then compare the composition of the molecules containing the same element—including, or not, the molecule of the element itself—and thence deduce the law of the existence of atoms, that is to say, the amount of each element which always enters, by whole multiples, into the molecules which contain them. We here have the atoms of Dalton which, in the present state of the science, express not only all that Dalton discovered, but also the composition of equal volumes of their vapours, and in the choice of which those doubts can no longer arise which embarrassed Davy and Wollaston. The ideas of molecules and atoms suggested to the student by this law are devoid of all considerations of form, size, continuity, or discontinuity; the only property indissolubly connected with them is that of ponderability; the very definition of matter.

Recollecting that no physical theory of the constitution of matter had yet been advanced which thoroughly conformed to chemical ideas, he insisted upon the advisability in teaching the molecular and atomic theory, to keep it free from all that is not absolutely essential, so that it may preserve sufficient plasticity to adapt itself to the progress of our physical and mathematical knowledge. For this purpose he thought it useful to allow the student in the first place to glance at the changes in the hypothesis of the constitution of matter, and then to cause him to estimate the degree of confidence they merit in the actual state of our knowledge. Having thus placed upon a solid basis the fundamental notions of atoms and molecules by the comparison of the composition of equal volumes of the bodies in the gaseous state, it becomes necessary to consider the difficulties which arise in the application of these notions when the vapour densities are wanting; he explained and justified the use of the various auxiliary criteria to which we have resource in these cases, proving them in the first instance by the touchstone of the theory of Avogadro and Clausius, by showing that they gave results in accordance with that theory whenever the two methods can be employed simultaneously.

He believed that we should never lose sight of the starting point, nor give the formulæ of all compounds as of equal probability. "It is not by concealing the obscurity of these questions that we shall enlighten the student; on the contrary, we should estimate each fact at its true value by showing him that our science does not merit an equal degree of confidence on all points." This forms the introduction, the preparation for the study of the transformations which matter undergoes; the real object and aim of our science.

The comparison of the atomic composition of molecules has led chemists to the law of substitution, to the theory of types of Dumas, then to that of Williamson and Gerhardt, and lastly to the theory of the different valency of atoms and their modes of union, or the so-called theory of atomicity which includes the former. Although at present it is impossible, in teaching chemistry, entirely to eliminate this latter theory, which gives a summary of several laws, and guides us ordinarily in the co-ordination and even prevision of a large number of facts, yet it is difficult to keep it within just bounds so as to avoid infusing into the mind of the beginner illusions which are dangerous for his intellectual education. In order to avoid this, it is advisable to bear in mind the progress of this doctrine and the actual phase of development which it has at present reached. It is still far from being a complete and well-established theory, but is in a state of transition; for although doubtless it embraces a large number of facts, as yet it does not embrace them all. It is only a partial representation of the reality, and that from a restricted point of view, showing but little relation to our views of the constitution of matter, for it is the result of a comparison of diverse facts expressed by means of the atomic and molecular theory. It is convenient, therefore, to consider each part of this doctrine exclusively in relation to the group of facts which has suggested it.

It is unadvisable to define the valency of atoms as a property inherent in them, and then to deduce as a corollary their different modes of union; on the contrary, it is preferable to regard each portion of this doctrine as a deduction from the observation and comparison of a determinate group of facts, until an opportunity offers to unite these fragments into one whole, not forgetting, however, to notice the gaps which exist, never going beyond what the facts themselves suggest, and never applying to all bodies indiscriminately, the laws which suit only a single group. For instance, we must not pass over in silence the facts that whilst certain elements are bi tetra- or even hexa-valent, others are tri- and penta-valent; but the pupil should be prevented from acquiring mechanical and geometrical ideas of the cause and effects of the valency of atoms, by frequently reminding him that chemical facts show nothing about the size, form, continuity, or relative position of atoms. If we are sometimes obliged to employ the expression, "relative position of atoms in the molecules," and even to represent them graphically, we must warn the student that these are only artifices to express certain transformations, and that we are really ignorant of the relative position of the atoms either in space or in the mutual action of different portions of matter. With these reservations, it is possible, in teaching to derive considerable advantage from the theory of atomicity and at the same time to avoid its inconveniences.

In the study of the transformations which matter undergoes, we should direct the pupil's attention, not only to the ponderable changes in the composition of molecules, but also to the electrical and calorific phenomena which accompany these transformations. Even from Lavoisier's time it has been recognised that we cannot separate the study of matter from thermic considerations; and every day the connection which exists between chemical and thermic phenomena becomes more apparent.

As in the study of ponderable changes we were guided by the law of the conservation of weight, so in the connection between chemical and dynamical phenomena we are guided by the law of the conservation of force; the two studies mutually supplementing and illustrating one another. Not only will the atomic and molecular theory and that of atomicity help us to compare dynamical phenomena, but the study of dynamical phenomena will show us analogies and differences between chemical actions which would not be observed in the ponderable equations. We should therefore instruct the student in the little definite knowledge which we at present possess concerning thermic and electric phenomena, and especially fix in his mind the fundamental notion of a mechanical equivalent, and the manner of comparing it with chemical action as expressed by the atomic theory. In this we should be aided by the previous or simultaneous instruction of the student in physics under the form and language of the thermodynamic theory.

The lecturer concluded by observing that in the choice of methods and of matter for a course of chemistry, it should always be borne in mind that it was eminently a progressive science, and that even at the time of its most rapid development. The student should start not only with a knowledge of certain definite and fixed principles, but with an aptitude and sufficient preparation to enable him to follow the science in its unceasing transformation and progress, whether he intends expressly to cultivate chemistry, or has only learnt the elements of the science as an auxiliary to other studies or professions. Moreover, the end of chemical instruction for both these classes of students is not only to fix in their memory a certain amount of knowledge, but to assist in their intellectual education. For this, chemistry of all sciences is one of the best, offering both in verbal and practical instruction—excellent occasions for the exercise and harmonious development of all the faculties of the human mind.

He had desired to call attention to what he considered to be the most efficient means of imparting a knowledge of chemistry so that it might serve as an instrument of intellectual education, and that the student, by following it in its ulterior developments, might judiciously apply it to the study of the other branches of natural science. If the attention of the eminent chemists and professors there present were once attracted to this subject, he felt certain that a bright light would be thrown on it, and that our young professors would find numerous suggestions to direct them in teaching chemistry, and that at the very moment when instruction in our science had become so difficult, on account of the rapid transformation which it was undergoing.

Dr. Williamson said, that those who were there present ought not to separate without some expression of the pleasure that they had felt on listening to so learned, vast, and eloquent a discourse, treating as it did of a most difficult and important problem. There was scarcely anything of greater moment in the scientific education of youth than the rightly setting before them those wonderful transformations of matter which it is the province of chemistry to explain. These great and growing truths, for, as the lecturer had said, they were growing truths, should be set before youth in such a manner as to form a coherent whole. He hoped to study this masterly discourse with profit and delight, and would now propose a vote of thanks to his illustrious colleague for the honour which he had done them in delivering to them the Faraday lecture.

Prof. Tyndall said he had heard the discourse with deep interest, for it showed that the lecturer knew the importance of a teacher's vocation, and that his province was not merely to communicate knowledge, but to do it in such a manner as to arouse an interest in and love of the subject in the pupil by presenting it in its proper relations. He would have welcomed the lecturer to that Institution, even had he come to tear in pieces the notions which he cherished regarding atoms and molecules; how pleasant it was then to find such a broad agreement between their views. The chemist cannot halt at equivalent proportions—he must ask himself whence they arise, and the inevitable answer is some form of the atomic theory. This theory, however, cannot be confined to chemical phenomena. The motions of those atoms and molecules underlie all our explanations of the physical cause of light and heat, and it is already taking up the field of magnetism and electricity. Consider, for example, the heat of gases, both as regards the motion of translation of the molecules which produce temperature, and the motions of rotation and vibration of their constituent atoms, which, though they do not express themselves as temperature, constitute a portion of the heat. Clausius has shown that even in the simplest gases nearly two-fifths of the whole heat is due to these internal motions; while in gases of complex molecular constitution which condense on combining, the ratio of the total heat to the heat of temperature is still greater. The experiments of Regnault, which show that the specific heat of a perfect gas at a constant volume is constant, proves, as Clausius has shown, that the one kind of motion is proportional to the others.

The lecturer had also referred to atoms of the same kind combining together, so that, free oxygen and free hydrogen being considered as composed of molecules each containing a pair of atoms, has certainly simplified the results. But it must not be forgotten that this combination of like atoms is widely different from that of unlike atoms. The union of oxygen with oxygen or nitrogen with nitrogen produces no such effects upon the luminiferous ether as the union of oxygen with nitrogen. With the same quantity of matter the amount of *vis viva* sent forth as radiant heat may be augmented a thousandfold, perhaps a millionfold, by the act of diverse combination. This act seems to carry with it a condensation of the ether to a dense atmosphere around the atoms. Had a cannon the power of gathering round itself a dense atomsphere, it would send forth a greater amount of *vis viva* as sound. A gun fired at Chamouni may be heard upon Mont Blanc, while the same gun fired on Mont Blanc may not be heard at Chamouni, because the air on which the concussion takes place is denser in the one case than in the other. In the same way the diverse atoms vibrating in the denser atmosphere formed on combination show their vast superiority as radiators over like atoms which, except in such special cases as ozone, &c., are incompetent to produce a similar condensation. The speaker then asked them to echo the resolution so well put to the meeting by Prof. Williamson.

THE OBSERVATORY ON MOUNT VESUVIUS

WHILE the scientific world and his own countrymen are rivals in doing honour to Prof. Palmieri for his zeal in remaining at his post in spite of all danger, it may be interesting to examine in some detail the work done at the Observatory of Mount Vesuvius. We know wonderfully little about the origin and mutual dependence of volcanic phenomena. This is due to a want of accurate observations. For the complete investigation we require first to know at what dates earthquakes and eruptions occur at different parts of the earth. Next we must have observations of the direction and exact hour at which a wave of disturbance passes different places whose positions are known. This gives us the velocity of the wave, and helps to determine the position, under the earth's surface, of the centre of disturbance; or, if a wave be propagated over the sea, we obtain a means of estimating the average depth of the intervening ocean; for the velocity of a wave increases with the depth of the sea. This method gives one of the best determinations we possess of the depth of the Pacific Ocean. But beyond this we must have observations made systematically at some place subject to earthquakes and volcanic eruptions. No place in Europe is more suitable for this than the neighbourhood of Mount Vesuvius; and it was for such observations that an Observatory was established there.

Everyone knows that Mount Vesuvius consists of a great cone of lava and ashes, at the top of which is the great crater. On the northern side, separated from it by the deep valley called the Atrio del Cavallo, rises the precipitous and semicircular Monte Somma. This once formed the crater of the volcano, and the present cone seems to have been formed inside that great crater at the time when Pompeii was overwhelmed. On a spur of rock, a mile or two in length, running down from the Atrio del Cavallo, the Observatory is placed. It is close to the well-known "Hermitage," or half-way house, in the ascent of the mountain. Being raised on this ridge above the surrounding country, it is comparatively safe from the molten lava that flows at times on either side of it.

The building itself is handsome; in fact it is to be regretted that so much money should have been devoted to the masonry instead of to additional instruments. On the ground floor are the inhabited rooms, all scantily furnished; but the pursuers of science cannot always expect bodily comfort. On the first floor we find the Museum, with a fine collection of minerals found on the mountain. Perhaps it may be as well here to correct a common mistake as to the nature of the yellow substance found about the craters, whose brilliant colours remind one so much of the Solfatara. This substance is not sulphur, but copper. The most interesting objects in the Museum are the "fumerolles," or smoke-holes. Occasionally at the end of an eruption you may see at the bottom of the crater a small cone of lava, with a hole in its top, through which the steam pours with a hissing noise like a wave breaking on a pebbly beach, or like a blast furnace, or as Pliny has it, like the grinding of a saw; the intensity of the sound varying with your position. These small cones are the fumerolles; they are a foot or two high; and Palmieri has actually had several of these natural chimneys cut off and transported to the Museum.

We now pass on to the Observing Room. There are solid piers carried up from the ground to support the instruments. First comes the elegant seismograph for the automatic registration of earthquake shocks. The object of the instrument is twofold: first to measure the direction and intensity of a shock; and, second, to write down a history of the earthquake. The shock may be either vertical or horizontal, or partly vertical and partly horizontal. For the vertical shocks a fine metallic point is suspended by a coil of wire over a cup of mercury. The coil of wire acts as a spring, and the slightest upward motion of the

earth is sufficient to cause the point to dip into the cup of mercury. This completes a galvanic circuit, which stops a clock at the exact half second at which the shock occurred, and rings a bell to call the observer, and also does other work which we shall speak of again. There are three or four helices of wire of different strengths, which support small magnets above a cup of iron filings. When a vertical shock occurs some of these magnets dip into the iron filings. To one of these a light index is attached for measuring the intensity of the shock.

For horizontal shocks there are four glass tubes. Each of them is bent twice at right angles, so as to form a U tube. One arm of this tube has more than double the diameter of the other, and is shorter. The four tubes point in the directions of the four cardinal points. Each tube has a certain quantity of mercury poured into it, and on the surface of the mercury, within the narrow arm of the tube, there rests a small weight attached to a silk fibre, which passes over a delicate ivory pulley, and has a counterpoise attached at the other end. Each pulley has an index and circular scale to mark the angle turned through. The extremity of a wire is fixed at a small distance above the surface of the mercury in each tube. If then a horizontal shock occur, the mercury rises in the corresponding tube; but it rises higher in that one which has its long arm to the north. The pulley is turned through a certain angle, which is measured by the index, and at the same time the mercury in rising comes in contact with the fixed wire, and so completes a galvanic circuit which rings a bell, and stops the clock at the exact half second when the shock occurred. If the shock comes from some intermediate point two of the indices will be moved, and the direction and intensity can be measured by observing both of them. We have seen up to this point that the instrument will measure the direction and intensity of a shock, will mark the time at which the shock occurred, and will ring a bell to attract the attention of the observer on duty, who may register succeeding shocks, or, if the earthquake has ceased, may reset the apparatus. But this is not all. The galvanic circuit, which is completed at the moment a shock occurs, releases at the same instant the pendulum of a second clock, which has been held out of the vertical by means of a detent. This clock allows a roll of paper to be unwound off a drum, as in any registering telegraph, at the rate of three metres an hour. A pencil rests nearly in contact with the strip of paper. It is connected with one arm of a lever, the other arm of which is slightly distant from an electro-magnet. As often as the current passes this end of the lever is attracted to the magnet, and the pencil in consequence is made to press on the paper, to be released only when the current ceases. By this means then a continuous history of the earth's trembling is registered, a pencil mark corresponding to a time of trembling, and a blank space to a period of cessation.

This instrument is extremely delicate, and registers motions of the earth which are too slight to be perceptible to the human frame. When we examined it some one happened accidentally to touch the casing of the instrument. The alarm was immediately given by the bell, and the two clocks were respectively checked and put in motion by the galvanic current.

The accompanying figure (borrowed from the *Engineer*, for the use of which we are indebted to the courtesy of the editor of that journal) may help to make the above description more intelligible. In Fig. 1, the clock A is shown with the pendulum arrested, as after a shock has occurred. The pendulum of the clock B is in a position ready to be set free when a shock occurs. At the same time the strip of paper *k k k* will be rolled on to the cylinder *i*, and at each trembling of the earth the electro-magnet D will cause a pencil to make a mark on the paper at the point *m*. P and R are two pillars, between which are shown the U tubes containing the mercury, the pulleys and indices are shown above. These pillars and tubes are also shown in plan. Metallic bars are seen connected with R, and passing over the short arms of the tubes. From these hang the wires that dip into the mercury. From the pillar P, metallic bars are also shown passing over the long arms of the tubes; to these are attached the wires that are almost in contact with the mercury, and which complete the circuit when a shock occurs. The metallic spring E, supported by the pillar T, above the cup of mercury *f*, is the apparatus for making a current during a vertical shock; *h h h* are the springs with magnets attached, which dip into iron filings. The index for vertical shocks is shown more clearly in Fig. 2.

For more violent shocks the heavy bob of a freely suspended pendulum is placed in the centre of a horizontal ring in which eight tubes are placed lightly, all pointing to the centre. From whatever direction a horizontal shock comes it will drive out one of these tubes. The tube driven out will show the direction of the shock, and the distance to which it is driven will show the intensity. This is also shown in plan (Fig. 3). The hole for the tube is also represented. There is also shown in section a cup of mercury, placed at the foot of the pillar G (Fig. 1), which has eight holes in its circumference just above the surface of the mercury. When a shock occurs mercury is driven out into the hole corresponding to the direction of the shock. The quantity of mercury determines the intensity. The battery is shown in Fig. 4, and needs no explanation.

In the same room there is apparatus for detecting and measuring atmospheric electricity. A gold leaf electroscope and a bifilar electrometer are observed regularly. These are successively put in connection with the conductor. This consists of a disc of metal above the roof of the house connected with an insulated metallic rod, supported vertically, and capable of being rapidly raised by means of a cord passing over a pulley. When not in use this rod is in connection with the ground. In making an observation the rod with the disc attached is quickly raised, thereby disconnecting it from the ground. The electricity of the atmosphere at the point where the disc is fixed affects the electroscope and electrometer. Prof. Palmieri prefers the conductor above-described to a conducting point or a flame, because he considers that these do not give comparable results, an objection which is not supported by all observers. He considers the same to be true of the method of dropping water.

After having made careful observations on atmospheric electricity for about a quarter of a century in a country where meteorological changes are more regular and less capricious than in our own island, there is no one whose deductions are more deserving of our attention; the more so as he considers that he has combined his researches into a definite law. His first fact is this:—*If within a distance of about fifty miles there is no shower of rain, hail, or snow, the electricity is always positive.* The single exception is during the projection of ashes from the crater of Vesuvius. During a shower he finds the following law universally to hold good:—At the place of the shower there is a strong development of positive electricity; round this there is a zone of negative, and beyond this again positive. The nature of the electricity observed depends upon the position of the observer with respect to the shower, and the phenomena will change according to the direction in which the shower is moving. Sometimes negative electricity may be observed during a shower; but this is always due to a more powerful shower farther off. These conclusions have been supported by means of telegraphic communication with neighbouring districts. It appears, then, that except when the moisture of the air is being condensed, there is no unusual development of electricity. These results are in accordance with the experiments of Palmieri and others, which show that

HOLE FOR TUBE

aqueous vapour in condensing developes positive electricity. No unusual development of electricity has ever been detected by him in a cloud when no rain is falling.

The above results, though falling short of what has to be done to complete the theory, are yet definite, and hence valuable, the more so if supported by other observers placed in equally favourable situations. But of the variations *in intensity* of positive or negative electricity nothing has been said.

Besides the fixed instruments at the Observatory others are used on the mountain. Gases are collected from cracks in the earth's crust, tubes being let down into them, and the gas sucked up by a kind of bellows to be examined at leisure. A portable spectroscope is also used during eruptions, and there is a larger one by Hoffman in the Observatory. From this Observatory we have received valuable information, and it is much to be regretted that equally efficient observatories have not been established in different parts of the world. Many portable and cheap instruments have been invented, most of which are described by Mr. Mallet in the "Admiralty Manual of Scientific Inquiry;" but there ought to be three or four as delicate as that on Mount Vesuvius. It is a pity that no observatory has ever replaced the ancient one of Empedocles near the summit of Etna, or even at Nicolosi, where the valuable services of Dr. Gemellaro might have been obtained. This would have been the more interesting, as Palmieri can detect shocks caused by that volcano, though the distance is enormous. With a third observatory, say in the Philippine Islands, we could not fail to increase our knowledge enormously.

From long practice Palmieri is able to predict eruptions. We remember well when we were enjoying his hospitality at the beginning of last year how he said, "This is a small eruption, but there is going to be a great one; I do not say it will be soon, it may be a year, but it will come." In almost exactly a year the great eruption did come.

GEORGE FORBES

ON THE DISINTEGRATION OF COMETS

THE main design of the following paper is to present at one view the historical evidence of the gradual disintegration of periodic comets. A few preliminary remarks, however, in regard to the received theory of comets and meteors, may not be destitute of interest.

The fact that in several instances meteoric streams move in orbits identical with those of certain comets was first fully established by the researches of Signor Schiaparelli. The theory, however, of an intimate relationship between comets and meteors was proposed and advocated by the writer several years previous to the publication of Schiaparelli's memoirs. In an article written in July 1861, and published in the "Danville Quarterly Review" for December of that year, it was maintained—

1. That meteors and meteoric rings "are the *débris* of ancient, but now disintegrated comets whose matter has become distributed around their orbits."*

2. That the separation of Biela's comet as it approached the sun in December 1845 was but one in a series of similar processes which would probably continue until the individual fragments would become invisible.

3. That certain luminous meteors have entered the solar system from the interstellar spaces.†

4. That the orbits of some meteors and periodic comets have been transformed into ellipses by planetary perturbation. And—

5. That numerous facts—some observed in ancient and some in modern times—have been decidedly indicative of cometary disintegration.

What was thus proposed as theory has been since confirmed as undoubted facts. When the hypothesis was originally advanced, the data required for its mathematical demonstration were entirely wanting. The evidence, however, by which it was sustained was sufficient to give it a high degree of probability.

* The name of *cometoids* was accordingly proposed for luminous meteors.

† Others, it was supposed, might have originated within the system—a view which the writer has not wholly abandoned.

The existence of a divellent force by which comets near their perihelia have been separated into parts, is clearly shown by the facts enumerated in the following lines. Whether this force, as suggested by Schiaparelli, is simply the unequal attraction of the sun on different parts of the nebulous mass, or whether, in accordance with the views of other astronomers, it is to be regarded as a cosmical force of repulsion, is a question left for future discussion.

1. Seneca informs us that Ephoras, a Greek writer of the fourth century B.C., had recorded the singular fact of a comet's separation into two distinct parts.* This statement was deemed incredible by the Roman philosopher, inasmuch as the occurrence was then without a parallel. More recent observations of similar phenomena leave no room to question the historian's veracity.

2. The head of the great comet of 389 A.D., according to the writers of that period, was "composed of several small stars" (Hind's "Comets," p. 103).

3. On June 27, A.D. 416, two comets appeared in the constellation Hercules, and pursued nearly the same apparent path. Probably at a former epoch the pair had constituted a single comet.†

4. On Aug. 4, 813, "a comet was seen which resembled two moons joined together." They subsequently separated, the fragments assuming different forms‡

5. The Chinese annals record the appearance of three comets—one large and two smaller ones—at the same time in the year 896 of our era. "They travelled together for three days. The little ones disappeared first, and then the large one."§ The bodies were probably fragments of a large comet which, on approaching the sun, had been separated into parts a short time previous to the date of their discovery.

6. The third comet of 1618.—The great comet of 1618 exhibited decided symptoms of disintegration. When first observed (on November 30), its appearance was that of a lucid and nearly spherical mass. On the eighth day the process of division was distinctly noticed, and on the 20th of December it resembled a cluster of small stars.||

7. The comet of 1661.—The elements of the comets of 1532 and 1661 have a remarkable resemblance, and previous to the year 1790 astronomers regarded the bodies as identical. The similarity of the elements is seen at a glance in the following table:—

	Comet of 1532.	Comet of 1661.
Longitude of Perihelion	111° 48′	115° 16′
Longitude of Asc. Node	87 23	81 54
Inclination	32 36	33 1
Perihelion Distance	0·5192	0·4427
Motion	Direct	Direct

The elements of the former are by Olbers; those of the latter by Mechain. The return of the comet about 1790, though generally expected, was looked for in vain. As a possible explanation of this fact it is interesting to recur to an almost forgotten statement of Hevelius. This astronomer observed in the comet of 1661 an apparent breaking up of the body into separate fragments.¶ The case may be analogous to that of Briela's comet.

8. The identity of the comets of 1866 and 1366, first suggested by Prof. H. A. Newton, is now unquestioned. The existence, then, of a meteoric swarm, moving in the same track, is not the only evidence of the original comet's partial dissolution. The comet of 1866 was invisible to the naked eye; that of 1366, seen under nearly similar

circumstances, was a conspicuous object. The statement of the Chinese historian that "it appeared nearly as large as a Tow measure,"* though somewhat indefinite, certainly justifies the conclusion that its magnitude has greatly diminished during the last 500 years. The meteors moving in the same orbit are doubtless the products of this gradual separation.

9. The bipartition of Biela's comet in 1845, as well as the non-appearance of the two fragments in 1865, when the circumstances were favourable for observation, are too well known to require more than a passing notice.

The comet of Halley, if we may credit the descriptions given by ancient writers, has been decreasing in brilliancy from age to age. The same is true in regard to several others believed to be periodic. The comet of A.D. 1097 had a tail 50° long. At its return, in March 1840, the length of its tail was only 5°. The third comet of 1790 and the first of 1825 are supposed, from the similarity of their elements, to be identical. Each perihelion passage occured in May, yet the tail at the former appearance was 4° in length, at the latter but $2\frac{1}{2}$°. In short, instances are not wanting of this apparent gradual dissolution. It would seem, indeed, extremely improbable that the particles driven off from comets in their approach to the sun, forming tails extending millions of miles from the principal mass, should again be collected around the same nuclei.

The fact, then, that comets and meteors move in the same orbits is but a consequence of that disruptive process so clearly indicated by the phenomena described. In this view of the subject, comets—even such as move in elliptic orbits—are not to be regarded as permanent members of the solar system. Their *débris*, however, thus scattered through space, and subject more or less to planetary perturbation, may casually penetrate the atmosphere, producing the phenomena of sporadic meteors.

NEWTON'S MANUSCRIPTS AND BIRTHPLACE

ALL Trinity men will, like myself, regret that Lord Portsmouth's gift, recorded in NATURE of June 6, should have been made to the library of Newton's University instead of to that of Newton's College. Surely for many reasons Trinity library is the most fitting depository for the Newton manuscripts. A catalogue of these papers is given in Collet's "Relics of Literature, 1823," pp. 190-194, consisting of eighty-two manuscripts, said to cover nearly eight thousand pages, mostly quarto or folio, besides six note-books, and many letters to Newton in English, French, and Latin. Unfortunately many of these papers relate to biblical or theological subjects.

When Dr. Pellet, by request of Newton's executors, examined these papers with a view to publication, he condemned all but five. These were :—

α 56 half sheets in folio, *De Motu Corporum.*

β 31 half-sheets in folio, being paradoxical questions concerning Athanasius (*sic*).

γ 12 half-sheets folio, an abstract of chronology, and 92 half-sheets folio, the chronology.

δ 144 quarter-sheets, and 95 half-sheets folio, being loose mathematical papers.

ϵ 40 half-sheets folio, the "History of the Prophecies," in ten chapters, and part of eleventh unfinished.

Of these γ was to have been printed, and α, β, and parts of δ and ϵ were to be reconsidered.

While on this subject, permit me to add an account of the present state of Newton's birthplace sent me by a lady at Stoke Rochford, where Newton attended a dame's school before going to the free school at Grantham :—

"Woolsthorpe, the birthplace of Sir Isaac Newton, is about half-a-mile westward from Colsterworth, and nine miles from Grantham. It has been thoroughly repaired by its present owner. At the top of the staircase, in a room to the left, Newton was born on Dec. 25, 1642. Over the fireplace is a small white marble slab recording the fact, with the well-known lines parodying Genesis i. 3. The only things in this room which remain unchanged since Newton's time are the door, which is massive, and rather ornamental in its workmanship, and a small cupboard close to the fireplace, the door of which is curiously carved. In another room a singular piece of furniture, made of wainscoting, stands in one of the corners, which looks like a small apartment taken from the main room. It is said to have contained Newton's books, instruments, &c. Above the door in front there is a shield with crossbones, and a few words to denote that the house was the birthplace of Newton. The sun-dial which Newton made and put upon the south side of his house was sent to the British Museum some thirteen or fourteen years ago."

C. M. INGLEBY

NOTES

WE are informed that Dr. Sharpey, who has for so many years filled with such great advantage to Science and personal distinction the post of Biological Secretary to the Royal Society, has recently sent in his resignation of that appointment. There is a very general hope among Fellows of the Royal Society that Prof. Huxley may allow himself to be nominated as his successor.

AT the meeting of Convocation of the University of Oxford, held last week, the honorary degree of D.C.L. was conferred on the following gentlemen :—Samuel David Gross, M.D. and LL.D., Professor of Surgery in the Jeaffreson Medical College of Philadelphia; Sir Benj. Collins Brodie, Bart., M.A., F.R.S., late Waynflete Professor of Chemistry; George Burrows, M.D., of Caius College, Cambridge, F.R.S., President of the Royal College of Physicians of London, and formerly President of the General Medical Council.

THE choice of the electors of the Waynflete Professorship of Chemisty at Oxford, vacant by the resignation of Sir B. C. Brodie, has fallen on Prof. Odling, F.R.S., who at present holds the position of Fullerian Professor of Chemistry to the Royal Institution, and Examiner in Chemistry to the University of London.

MR. EDWIN RAY LANKESTER, B.A., late junior student, Christ Church, has been elected to a Natural Science Scholarship at Exeter College, Oxford. Mr. Lankester was elected to the Burdett Coutts Scholarship in 1869, and to the Radcliffe Travelling Fellowship in 1870. There were four candidates.

IN accordance with the intimation which we gave last week, Mr. G. B. Airy has been gazetted a K.C.B., a graceful acknowledgment of the claims of representative men of science to recognition by the State.

WE have to record the death, on the 16th inst., in his 82nd year, of Colonel W. H. Sykes, F.R.S., M.P. for Aberdeen. He was a distinguished officer of the East India Company, and occupied the post of chairman of its Board of Directors at the time of the surrender of its Imperial functions. Colonel Sykes was always a firm friend to scientific research, and was himself possessed of no mean scientific attainments.

MESSRS. C. F. J. YULE and W. J. Sollas have been elected to Foundation Scholarships for proficiency in Natural Sciences at St. John's College, Cambridge. Each has been twice placed in the first class in the College Examination in Natural Sciences, and Mr. Sollas obtained in 1870 the exhibition of 50*l.* per annum offered by the College for competition to students in Natural Science not yet members of the University.

THE following is the list of those who have passed the special examinations in Natural Sciences for the ordinary B.A. degree at the University of Cambridge:—Chemistry—First Class: Porter, Clare; Loder, Trinity; Dent, Trinity; Corbet, St. John's. Second Class (in alphabetical order): Flood, Jesus; Savary, Trinity; Thomas, St. John's; Winder, Christ's. Geology—First Class: Jesson, Trinity. Botany—First Class: Smith, Christ's; Gibb, Down; Standert, Corpus; Norcock, Corpus. Second Class (in alphabetical order): C. W. H. Evans, Caius; Gibson, Christ's; Hamilton, St. Peter's; Hughes, Clare; Norton, Clare; Tamberlain, Trinity. Ægrotat: Moore, Corpus. Zoology—First Class: Bird, Trinity. Second Class (in alphabetical order): Campbell, Caius; Clutton, Clare; Leatham, Trinity.

SCIENCE has sustained a great loss in the West of England by the death of Mr. J. S. Enys, of Enys, near Penryn. In conjunction with Sir Charles Lemon and Mr. Davies Gilbert, he assisted science in every way that one of the largest landed gentlemen in the county could do. The Falmouth Polytechnic, and most others of the Cornwall scientific institutions, will miss the support which Mr. Enys so largely and constantly afforded them. Many of his geological and kindred works have been printed in the "Proceedings of the Royal Cornwall Institution," and by liberal subscription he assisted scientific periodical literature. He died, an ardent nature-worshipper, in his 76th year.

MR. GREGORY, the new Governor of Ceylon, we are happy to hear, not only takes great interest in the wonderful archæological treasures of the island, but also intends to do his best to promote the course of science there. A regular curator, a zoologist, will probably be appointed to the Colombo Museum, and if he does half as much work amongst the fauna of Ceylon as Mr. Thwaites has done amongst the flora, biological science will profit in no small degree thereby. We wish Mr. Gregory all success, and hope he may secure a good man for the post.

THE great provincial meeting of the Royal Horticultural Society will be held next week at Aston, near Birmingham, and promises to be a brilliant one. The proceedings will be opened on Tuesday, the 25th inst., by H.R.H. Prince Arthur.

PROF. HUMPHRY commenced his course of three lectures on Human Myology at the Royal College of Surgeons on Monday last. He spoke of the various provisions, such as obliquity of the direction of fibres, insertion near the centre of motion, passage through loops, &c., which are for the purpose of lessening the range of muscular action required, and so of shortening the fibres of muscles. The mechanical disadvantage resulting from this is, he observed, more than compensated for by the greater number of fibres brought to bear by means of tendons upon given points, and by the convenience of massing the fibres in certain positions, as well as by greater strength in the muscle itself. He next entered into the morphology of the muscles of the trunk, neck, and head. All of these he regarded as modifications of, or derivatives from, that structure which in the fish forms the great lateral muscle; and he showed how the parts corresponding with the septa of the lateral muscle sometimes form inscriptions in the muscles, and sometimes become converted into tendons, as well as into osseous and cartilaginous structures. This subject was discussed at considerable length. In speaking of the intercostal muscles, he gave mechanical reasons for believing that both the external and the internal intercostal fibres are, in their whole extent, agents in inspiration, and that the internal intercostals do not, as they have been supposed to do by some authors, act as depressors of the ribs at parts of the intercostal spaces.

A PAPER will be read at the Horological Institute on Tuesday, June 25, on "The Compensation and Adjustment of the Hemispherical Cup Arms of Velocity Anemometers," by Mr. John James Hall, F.M.S.

THE Franklin Society of Mobile was organised in the year 1835, under charter of the State of Alabama, for the purpose of promoting intellectual culture, literary taste, and other kindred objects. Its operations were suspended a little before the outbreak of the late American war, in consequence of the destruction of its hall, furniture, and a part of its library by fire, and have only recently been resumed. A suitable building has been purchased and remodelled, and arrangements are in progress for the inauguration of lectures and for the extension of the privileges of the Society's library beyond its own membership to the public at large. The library, however, is as yet but limited, and the ability of the members of the Society has been well nigh exhausted in the expenses incident to the purchase and fitting up of a new building. At a recent meeting it was resolved that a committee be appointed to correspond with the officers of similar societies in the several States, and with such other persons as the committee may think proper to address, and to request donations or loans of books, manuscripts, paintings, engravings, or other works of art. We commend the movement to those who have the means and inclination to contribute to objects of this nature. Shipments may be made to the "Franklin Society, Mobile, Alabama," the freight on which will be paid by the Society; or parcels may be sent to W. E. Mickle, Secretary Mobile Franklin Society, care of E. Stock, 62, Paternoster Row.

THE Austrian Government steamer *Admiral Tegethoff* sailed from Bremen on Thursday last, on its North Pole expedition. A farewell banquet, at which Count Zichy and Dr. Petermann were present, was given to the members of the expedition at Geestemunde.

IT is reported that the Emperor of Russia is projecting the junction of the Black Sea with the Caspian by a short canal connecting the Manutch, an eastern tributary of the Don, with the Kerma, a river running into the Caspian. The total length of the communication will be 680 versts, or 90 German miles; but the length of the canal will be only about one German mile. The piercing of the mountain which separates these rivers will, however, be an engineering work of gigantic magnitude, and is calculated to require the labours of 32,000 workmen for six years, and to cost 81,000,000 roubles.

PROF. DAWSON, F.R.S., delivered the Annual Address to the Natural History Society of Montreal on May 18. In it he strongly attacked the Darwinian theory of Evolution, which, in its extreme form, he considered had a tendency to "prostitute natural history to the service of a shallow philosophy," and to lead to "the destruction of science, and a return to semi-barbarism." He held that his researches on the shells of the Gulf of St. Lawrence and the coasts of Labrador and Greenland, showed that it was impossible that any changes of the nature of evolution were in progress; but that all these species had remained the same, even in their varietal changes, from the post-pliocene period till now. Principal Dawson then referred to the controversy raised by Dr. Sterry Hunt with regard to the use of the names Cambrian and Silurian in geology; and concluded with a sketch of the recent operations of the society in dredging the Gulf of St. Lawrence.

THE members of the Australian Eclipse Expedition, if they were unsuccessful in the primary object of their voyage, saw some strange things along the shores to the north of the great continent of Australia. Mr. Foord tells a wonderful story, "amply attested by witnesses," of a fish with four hands. This extraordinary creature was found crawling on a piece of coral dredged up from the bottom of the sea. "The body was that of a fish," says Mr. Foord before the Royal Society on January 22, "but wonderful to relate, it had in the place of fins four legs terminated by

what you might call hands, by means of which it made its way rapidly over the coral reef. When placed on the sky-light of the steamer, the fish stood up on its four legs, a sight to behold! It was small, and something like a lizard, but with the body of a fish!" It is to be hoped that a full and scientific description of this latest marvel of deep-sea dredging may soon be published, as the specimen appears to have been brought back to Melbourne. Mr. White, too, of the same Expedition, tells strange tales about the rats. "The little island," he said, "upon which we pitched our tent was overrun with them, and what was most extraordinary, they were of every colour from black to yellow, and some tortoise shell!"

AMONG other collections made by Prof. Marsh during his explorations in 1871 were additional specimens of the pterodactyl, first obtained in 1870. Portions of five individuals were procured; and among them nearly all the bones of the right wing of one, which exhibited the pterodactyl structure in its perfection. The teeth found with the other remains were somewhat similar to those of the pterodactyls of the Cretaceous of England, being smooth, compressed, elliptical, and somewhat curved. A second species, still larger than the other, was obtained in the Upper Cretaceous, near the Smoky River, in Western Kansas. The expanse between the tips of the fully-extended wings was probably as much as twenty-two feet. In all, Prof. Marsh has determined the existence of three species from the same region, which he characterises in the April number of the *American Journal of Science*. In the same journal Prof. Marsh refers to the interesting discovery that the body of mosasauroid reptiles was probably covered with plates, as in some crocodiles, the head itself being smooth. This fact has been ascertained in regard to specimens of all the American genera, so that probably all the species possessed it.

THE second Report of the Geological Survey of Indiana, made during the year 1870, under the direction of Mr. E. T. Cox, State geologist, has just made its appearance, and, like its predecessor, appear to be a work of much scientific value. In addition to the series of reports upon the geology of the counties, it embraces a paper upon the Western coal measures and Indiana coal, and a paper upon palæozoic zoology, and closes with an extended manual of the botany of Jefferson County, Indiana, prepared by Prof. A. H. Young, of Hanover College. In this the total number of indigenous species is given at 537, those introduced numbering 72.

ANOTHER book of excellent typographical execution has just appeared from the public printing-office of the United States, in the form of the astronomical and meteorological observations made at the United States Naval Observatory during the year 1869, under the direction of the superintendent, Admiral B. F. Sands. This volume, forming a stately quarto of over 900 pages, is prefaced by a detailed account of the transit circle, the meridian transit instrument, the mural circle, and the equatorial of the observatory, and followed by a statement of observations made with these instruments. The volume also contains the meteorological observations for 1869, the positions of the sun, moon, and planets during that year, as made with different instruments, &c. The report of the total eclipse of December 22, 1870, which has already appeared as a separate memoir, is included in this volume, as also an appendix embracing the zones of stars observed with the mural circle in the years 1846, 1847, 1848, and 1849. The observatory is now in excellent condition, and includes in its working force some of the best astronomers and mathematicians of the country; among them Profs. Newcomb, Hall, Harkness, Eastman, &c. The completion of the gigantic telescope now in process of construction by Alvan Clark will constitute an important addition to the means of research, and will doubtless be turned to good advantage.

ON THE SOUND MADE BY THE DEATH'S HEAD MOTH, "ACHERONTIA ATROPOS"

THE singular cry produced by the Death's Head Moth has for a long time been known to naturalists, and the question of the exact method of its production has given rise to much discussion. To judge, however, from the latest writings on the subject, the matter is considered even now as being far from definitely elucidated. In the autumn, about six years ago, I was lucky enough to rear over a hundred imagos of *Acherontia atropos* from pupæ obtained from potato diggers in the neighbourhood of Bristol. I made then some observations on the production of the sound in question, but I did not consider them as sufficiently perfect for publication. I got no more specimens until last autumn, when I obtained a single imago from ten pupæ, but on this I made an experiment which I believe to be crucial in the matter. Absence from England, however, on the Government Eclipse Expedition, has prevented my giving an account of my experiment until now.

On looking into the literature of the subject, in which task I have been kindly assisted by Prof. Westwood and Prof. Rolleston, I found it in its extent far exceeding my expectations. The number of theories which have been invented to account for this apparently simple phenomenon is astonishing; and as the history of the question is really very interesting, I shall commence by giving as complete an account of what has been written on the subject as I have been able to obtain by reference to works in the Radcliffe, Bodleian, and Linnean Society's libraries, and in that of Prof. Westwood.

The earliest writer on the subject was Reaumur (Mémoire pour servir à une Histoire des Insectes, 1734-1742, vol. i. pl. 14), who suggests that the noise is most probably due to the same cause as in certain scarabei, which produce a sound by the rubbing together of certain of their scaly parts. Later on (*loc. cit.* vol. ii. p. 24) Reaumur states that he has made further experiments, and concludes that the sound is produced by the rubbing of the proboscis against the palps. He held the palps aside from contact with the trunk, and the sound ceased. But he is of opinion that air may have something to do with the matter, and makes his statement with caution. There is a membrane stretched at the base of the trunk, he says, which may have something to do with it; and finally, "Je ne me lasserai point de répéter que nous dévons nous attendre, que dans les plus petits sujets il res'era toujours quelque chose que nous ignorons." It would have been well if some of the many subsequent writers or the subject had profited by this sage remark. The next author is Roesel (Insecten Belustigung: Nürnberg, 1755, § 16), whose observations, according to Wagner, were very superficial; and who considers the sound due to friction between the opposed surfaces of the abdomen and thorax. Next comes Rossi (Istoria della Farfalla a testa di Morto, Opuscoli di Milano, Ann. 1782) who is the first to arrive at a correct result, and says the sound is due to expiration of air through the trunk. Schröten (Der Naturförscher, xxi. Stück: Halle, 1785) gives as a cause the rubbing of the trunk against the head. Engramelle, as quoted by Passerini, without special reference, makes the sound come from the part of the insect called the spallette.

There is now a considerable chronological interval, and then Godart and Dupronchel (Hist. Nat. des Lépidoptères de France. par M. Godart. tom. iii. pp. 18 et 19) report a letter from M. Lorey, retired army surgeon-major, who describes a peculiar pair of organs, situate on the sides of the abdomen, surrounded by long hairs, which, when the animal squeaks, may be seen to elevate themselves, and form a conical cavity leading to an opening. He considers the sound to be produced by the passage of the air through this opening. It will be seen further on that this peculiar pair of organs was subsequently described as a discovery by two writers ignorant of the literature of the subject.

Next comes Passerini, who went to the very root of the matter, and explained the whole thing correctly and clearly in a monograph entitled, "Osservazioni sopra la Sphinx Atropos o Farfalla a testa di Morto," del Dottore Carlo Passerini: Pisa, 1828. He commenced his experiments in 1824. He first disposes of Lorey's theory by showing that his peculiar organs exist only in the male insect, whereas both male and female Death's Heads produce the sound; and further, that the same organs exists in the males of other moths, as *Macroglossa stellatarum*, and *Sphinx convolvuli*, which produce no sound. Next he records this startling experiment:—A moth may be divided in two through the middle of the thorax, and the anterior extremities will still continue

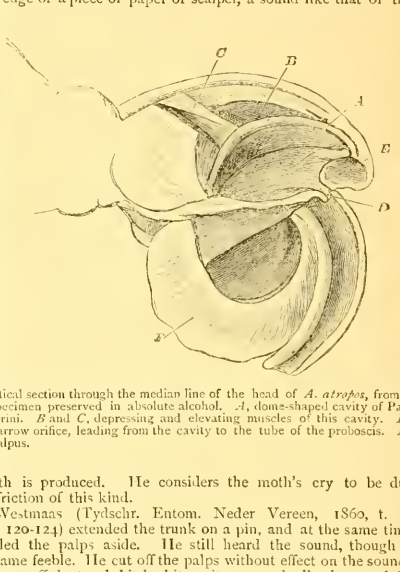
to speak. This experiment disproves absolutely all theories which connect the sound with the abdomen in any way, by friction or otherwise. He next removed successively from a moth the palps, the trunk, and the spallette, and the insect nevertheless continued to squeak. He then cut away carefully with a sharp knife the horny top of the head of another specimen, and observed certain muscles rising and falling in rapid motion when the animal squeaked, but remaining quiescent as soon as the sound ceased. As long as these muscles were left intact the insect might be mutilated in almost any manner without the sound being stopped. If these muscles were divided longitudinally, or transversely, the power to emit sound was lost. In quite a fresh specimen, he says, in examination after death, the upper part of the head is found filled with an indurated cellular structure, and beneath this are found the elevating and depressing muscles. Beneath these is an inclined shining horny surface of triangular form leading to a narrow transverse aperture corresponding with the opening of the proboscis tube. At the back of the incline is a very fine aperture, leading into the body of the *Sphinx*. He concludes that the air enters the cavity of the head by the fine aperture, and is driven out through the narrow transverse one by the action of the muscles just described, and that thus the sound is produced.

Chavannes wrote on the subject (Act. Soc. Helv. Sc. Nat. 17; Isis: Genève, 1832, pp. 93-94), but I have not been able to refer to his memoir, nor to that of Rochebrune (Act. Soc. Scient. Bordeaux, 1832, t. 5, pp. 120-122, tab. 1.) Then we have H. Burmeister (Handbuch der Entomologie, Berlin, 1832), who after citing Reaumur and Rossi says, "This much is certain, the organ of voice is seated in the head." Then Vallot (*L'Institut*, 1834, II., No. 34, p. 7), who demolishes to his own satisfaction all previous theories, and adopts that of Johet, which considers the sound to be produced by the striking of the wings in rapid movement against certain parts. Wagner (Müller's Archiv für Physiologie, III., 1836, pp. 60 62), after satisfying himself that the sound came from the head, unrolled the trunk, and found that the sound became feebler, but did not cease. When he held the two halves of the trunk apart, or cut off one or both up to the base, the sound ceased. He found just in front of the true stomach a crop very large, distended with air, and filling up the whole anterior part of the abdomen, and opening into the posterior extremity of the œsophagus. He could not find any special apparatus in the trunk, but he says that there appears to be a fine slit-like opening at the basis of this organ on its inferior surface, formed by the imperfect closure of the two halves of the trunk. This may have something to do with the matter. He could not find Passerini's cephalic cavity. The proboscis has strong, transversely-striated muscles. Duges (Traité de Physiologie comparée, par A. Duges: Montpellier, 1838, vol. ii. p. 226) ascribes the noise to the rubbing together of the opposed edges of the two halves of the proboscis.

We have theories already in abundance, and there are more yet to come; but we now come on repetitions of previous theories by persons who either had not access to, or were too lazy to consult, the writings of the original inventors of them. Dr. Alex. V. Nordman (Bull. Acad. St. Petersburg, 1838, t. 3, pp. 164-193) says the sound is seated neither in head nor proboscis, but in the abdomen; and he then proceeds to give an elaborate description of the peculiar organs already discovered by M. Lorey, and he congratulates himself not a little on his having been able, after the failure of so many previous investigators, to make this discovery, and to set the matter finally at rest. We next have observations and experiments made by MM. Duponchel and Guerin (Ann. Soc. Ent. France, 1839, t. 8, pp. 59-65). To show that Passerini was wrong, they compressed the trunk at the base sharply with forceps, and also stopped the end of the proboscis, but apparently in a very insufficient manner. The noise did not cease. They had only one individual on which to operate, and therefore could not afford to mutilate it and repeat Passerini's experiments. Their conclusion is that the noise has the nearest analogy to that emitted by Longicorn beetles, which is produced by the rubbing of the prothorax against the smooth portion of the scutellum. Goureau (Ann. Soc. Ent. France, 1840, t. 9, pp. 125 128) says, "Reaumur, Passerini, Lorey, all are wrong. There is no special organ for the sound. The sound is of a double nature. There is one shrill part of the sound which proceeds from the vibrations of the thoracic rings; in another part a grating sound is caused by the rubbing of the shoulders against the thorax." Abicot (Ann. Soc. Ent. France, ser. 2, 1843, t. 1, Bull. p. 50) says that amputation of the trunk stops the noise, therefore Goureau is wrong.

Ghiliani (Ann. Soc. Ent. Fr., ser. 2, 1844, t. 2, Bull. pp. 72, 75) comfirms Passerini. He cut off the head and the sound stopped. He held the trunk horizontally, and at various inclinations, the sound continued; he removed the palps, the sound continued; he dipped the head in oil, the sound ceased. He then amputated the trunk at its root. Three apertures were formed by the operation, one corresponding to each half of the proboscis, the other probably to the prolongation of the buccal cavity situate just above the trunk, and opened by the knife when amputating the trunk. A green liquid flowed from the third opening over the cut root of the trunk, in which liquid large bubbles were seen to be formed by the expiration accompanying each sound. On closing the apertures the sound ceased. He is unable to explain how inspiration and expiration are managed. Paris (Ann. Soc. Ent. France, ser. 2, 1846, t. 4, Bull. pp. 96, 142) thinks the noise due to a mucous fluid which the insect forces by aspiration, with the assistance of the palps up and down inside the proboscis, comparing the process to the flow and reflow of a liquid in a suction and force-pump.

J. Vander Hoeven (Tydschr. Entom. Neder Vereen, 1859, t. 2, Stück 4, pp. 117-122) says the source of the sound is certainly in the head. In an Indian species of *Acherontia* he has found tuberosities all over the basal portion of the trunk. The exterior surface is beset with stiff bristles. On rubbing this surface against the edge of a piece of paper or scalpel, a sound like that of the



Vertical section through the median line of the head of *A. atropos*, from a specimen preserved in absolute alcohol. *A*, dome-shaped cavity of Passerini. *B* and *C*, depressing and elevating muscles of this cavity. *D*, narrow orifice, leading from the cavity to the tube of the proboscis. *E*, palpus.

moth is produced. He considers the moth's cry to be due to friction of this kind.

Westmaas (Tydschr. Entom. Neder Vereen, 1860, t. 3, pp. 120-124) extended the trunk on a pin, and at the same time pulled the palps aside. He still heard the sound, though it became feeble. He cut off the palps without effect on the sound. He cut off the trunk bit by bit, as it was gradually shortened the sound diminished. A fluid exudation covered the end of the trunk, and he saw bubbles of air formed in this as each sound was emitted. He confirms Passerini. He notices that the insect produces a louder sound when the trunk is coiled up. The moth when emitting a sound elevates the front of its body, and uses an evident effort. He stopped the aperture of the trunk with grease, the crying ceased; he kept one specimen half a day with the trunk aperture thus closed, it emitted no sound, but on the grease at last being removed squeaked at once. In order to test Wagner's theory, he squashed out the abdomen quite flat, so as to destroy any air cavity it might contain; the animal still squeaked. Chapronnier (Ann. Soc. Ent. Belg. *Comptes Rendus*, pp. 16, 17) says that the noise produced by the larva is due to the snapping together of the mandibles. An imago, which he bred, which had a deformed head, emitted no sound; therefore the sound organ is situate in the head.

Finally, we find some discussion of the matter in the *Entomologist*. Edward Newman (*Entomologist*, August 1865, p. 284), says, "With regard to the sound produced by the pupa and imago, A vast deal has been written, but nothing worth repeating." But he surely cannot have sufficient grounds for this sweeping demolition of previous authors, and certainly cannot have consulted this "vast deal which has been written;" for he proceeds to enunciate the very theory first put forth in the year 1755 by Rossel, and subsequently revised by Duponchel in 1839.

E. A. Johnson (*Entomologist*, Nov. 1865, p. 325, *Field* newspaper, Oct. 24, 1865) describes the organs discovered by M. Lorey before the year 1828, and subsequently by Nordman, in 1838. W. H. Taylor (*Entomologist*, Nov. 20, 1865) brings forward Passerini's objection to Lorey's theory, viz., that males only have these organs, while both sexes squeak, and that other species which produce no sound possess these organs. Thus does history repeat itself. In the same page of the same journal we have some remarks on the subject from the Rev. A. Preston, who, when sticking his pin-point into an insect in killing it, and moving the pin up and down against a muscle, heard a sound just like that of the mouth. He does not, however, from this observation draw any very definite conclusion.

It will be found that there are eleven distinct theories in all which have been put forward to account for the cry of this moth. By far the greater number attribute the phenomenon to friction of various parts, two to an expiratory effort, one to rapidly repeated percussion, and one to the intervention of a fluid.

The foregoing contains the pith of all the writings on the subject which I have been able to meet with. I have no doubt there are many others in existence, but I hardly expect that I have missed any of importance.

I am not aware whether all known species of *Acherontia* emit a sound; but a closely allied species in Ceylon is described by Sir Emerson Tennant, in his "Natural History" of that island, as doing so; and I was lately, whilst in Ceylon, informed by several residents that such was the case. This Ceylon species is probably *Sphinx Acherontia Lethe*, described by Prof. Westwood in his "Oriental Entomology," p. 87.

I now pass to my own observations on the subject. I was killing a specimen out of the large number which, as stated above, I bred about six years ago, by means of a solution of cyanide of potassium, which I was using with a pen in the ordinary manner, the animal squeaking loudly under the operation. A drop of the fluid happened to fall on the extremity of the proboscis. I noticed that at each squeak a large bubble was formed, showing a forcible expiration from the organ. I repeated this experiment constantly with water, and always with the same result. I further extended the trunk with a pin during the emission of the sound, and noticed a modification in the tone of the cry, which varied with the amount of extension. These experiments convinced me that the sound came from the proboscis, and was produced by an expiration. I at that time knew nothing of the literature of the subject, and very little of anatomy, and I unfortunately made no further observation or experiments in the matter; and it was not till last autumn that I was able to pursue the subject further on a single specimen which I was fortunate enough to rear. This specimen was a very lively one, and it squeaked freely. I placed a tight ligature on the extremity of the proboscis whilst it was in the act of emitting its cry. The noise stopped instantly. I kept this specimen two days, and handled it constantly, bullying it in all sorts of ways to try and get it to squeak, but without result. After the proboscis had been thus ligatured for two days, I amputated the lower portion of the trunk just above the ligature. The animal instantly began squeaking, and continued to do so at intervals for two days more, when I killed it in order to examine the anatomy of its head. I fancied my experiments at the time quite novel, and it was only the other day that I found that similar ones had been made by Ghiliani and Westmaas; but the method of ligaturing the proboscis, with subsequent amputation above the ligature, is, I think, more satisfactory than Westmaas's use of wax.

After these experiments, taken in confirmation of what has already been done in the matter, I think there can be no doubt that the sound is produced by expiration through the proboscis. We have now to consider—How is this expiration effected? Whence comes the air expired? and Whereabouts in the proboscis or head is the actual spot where the sound is formed? I think it will be found that Passerini's explanation is in almost every respect satisfactory. I had no time to dissect my Death's Head whilst in the fresh state last autumn, but preserved it in absolute alcohol. The accompanying drawing of a preparation made from it may therefore need slight modification on further investigation; but in the main it will be found correct. The figure represents a magnified view of a vertical section along the median line of the head. A is the large dome-shaped cavity, evidently the one described by Passerini, and which R. Wagner could not find. This cavity has a hard chitinous floor, which is prolonged forward so as to project over the proximal extremity of the proboscis (seen here in section with its end amputated), and there ends in a sharp edge, which forms, with the anterior wall of the cavity, a narrow transverse slit, leading to the proboscis tube, just as described by Passerini. Resting on the roof of the dome-shaped cavity are Passerini's muscles, B and C, with some cancellar-like tissue between them and the external wall of the head. It would obviously be easy to expose these muscles as Passerini did with great ease and very little disturbance to the insect's functions, and I cannot see any reason to doubt that they would be found in action just as he describes.

Passerini does not figure the muscles or describe them accurately. He merely calls them elevating and depressing muscles. The muscle C must obviously on contraction raise the dome-shaped cavity, whilst B must depress it. An alternate action of the two muscles would cause the cavity to act as a bellows, and inhale and expire air through that aperture which allowed it to pass and repass most freely. Passerini believed that the air entered the cavity by the œsophageal opening at its hinder part, which he describes as very narrow (*loc. cit.*, p. 6) ("Da tutto cio che ha esposto credo poter concludere che l'aria dall'interno della sfinge vien portata alla cavita muscolare della testa per mezzo dell' esilissima tuba"), and was expelled then by the proboscis; but that this is really the correct explanation is scarcely probable. First of all, the posterior opening into the cavity must be very small indeed. I cannot find it at all in the present specimen, and it is highly probable that it may often be aborted altogether, as is the case in most butterflies. Moreover, how should the air get into the œsophagus? Certainly not from the abdomen as supposed by Wagner, for Westmaas showed that the animal could squeak after the abdomen was squashed out flat, and Passerini himself showed that an insect would emit the sound after it had been divided in two through the middle of the thorax, an experiment which of itself is sufficient to overthrow his own view. The opening into the proboscis being by far the largest leading into the dome-shaped cavity, the air probably finds ingress as well as egress by this aperture. And if I remember rightly the bubbles formed on the end of the proboscis in my experiments always collapsed between the squeaks, showing this to be the case. I think that there can further be no doubt that the note is formed at the narrow slit-like opening, the sound being modified by passage through the proboscis tube, and by vibrations therein set up, this latter to account for modifications produced by straightening the trunk or by gradually removing it bit by bit from below (Westmaas).

I further think it probable that there is a movement of the proboscis concerned in the production of the sound. If the base of the proboscis were drawn a slight distance directly forward at each inspiration, the upper opening of that organ would be brought more immediately beneath the narrow passage communicating with the dome-shaped cavity, and the ingress of air would be rendered more free. Then if at expiration the base of the proboscis were retracted again, the aperture of egress would be very much contracted, and the formation of the sound facilitated. It would be interesting to observe whether such a motion of the proboscis takes place. I think I remember to have noticed a slight movement of the trunk during the emission of the sound.

It is most extraordinary that the seat of the sound should ever have been imagined to be anywhere but in the head. One has merely to listen to the animal to detect at once where the sound comes from. It would seem as if many writers on the subject had commenced their observations with a determination to find some other seat for the cry. The animal is a large one, and one could as easily persuade oneself that a mouse's cry proceeded from the tip of its tail as that of a Death's Head from its abdomen. Should I obtain specimens of *A. atropos* this autumn, I hope to repeat Passerini's experiments, and also make certain whether inspiration as well as expiration takes place through the proboscis; I think also that Wagner's narrow slit on the under surface of the proboscis should be experimented on.

H. N. MOSELEY

SCIENTIFIC SERIALS

THE *Geological Magazine* for June (No. 96) opens with an interesting article by Mr. Dyer on some fossil wood from the Lower Eocene of Herne Bay and the Isle of Thanet, in which the author describes and figures the microscopic structure of the wood of a Dicotyledonous tree, showing the peculiar phenomenon known under the name of "tylose."—Mr. G. Poulett Scrope communicates some notes on the late eruption of Vesuvius.—From Mr. T. McKenny Hughes we have a note entitled "Man in the Crag," in which the writer discusses the interpretation to be given to certain crag sharks' teeth with holes bored in their substance, and sometimes through them from side to side, which have been supposed to be the work of human hands. Mr. Hughes is of opinion that there is no evidence to support this opinion, and that the cavities in question have been produced by boring mollusca.—Mr. A. R. C. Selwyn, Director of the Canadian Geological Survey, notices the occurrence of some fine fossil footprints in a stratum of dark shale belonging to the Carboniferous series of Nova Scotia, and these footprints are described and figured by Principal Dawson. The latter writer states that the principal footprints are of two kinds—a large one resembling the form described by him as *Sauropus sydnensis*, but having a strong claw on the fifth toe of the hind foot, which has left its mark strongly impressed upon the slab containing the prints, and a smaller impression, sometimes trifid, but occasionally showing the marks of four or five toes. The former (which he names *Sauropus unguifer*) he thinks may have been made by *Baphetes planiceps*; the latter perhaps by a species of *Dendrerpeton*.—Mr. James Geikie concludes his valuable series of papers on changes of climate during the Glacial epoch, and gives an important tabular view of the Quaternary deposits of the British Islands, with their equivalents in some other countries. Mr. G. H. Kinahan notices the supposed middle gravels of the drift of Ireland. The Rev. O. Fisher describes the occurrence of a worked flint in the brick-earth of Crayford. The Rev. T. G. Bonney has a paper on supposed Ice scratches in Derbyshire, which he regards as slickensides; and Prof. Traquair furnishes a supplementary note on *Phaneropleuron* and *Uronemus*.—Among the notices we may mention an account of the human skeleton lately discovered in a cavern at Mentone.

Revue Scientifique, Nos. 43-50.—No. 43 commences with an article by M. Wolf on the Transit of Venus in 1874, illustrated by five diagrams. Mr. Keith Johnston's paper read before the Royal Society of Edinburgh on the Lake-basin of Eastern Africa is translated. In subsequent numbers we find a continuation of M. Claude Bernard's course of lectures on Animal Heat. A paper presented by M. Ch. Grad to the Geographical Society of Paris on the resources of Alsace. Dr. Günther's paper on *Ceratodus Forsteri* is translated from NATURE. M. Dumas contributes an article on the higher instruction in Agriculture at the Central School of Arts and Manufactures in Paris. M. G. de Morillet on Cave-man; epoch of the Madeleine. M. Grandidier contributes a most interesting series of papers on his scientific voyage to Madagascar. Translation of the chapter on the evolution of religious ideas among savages, from Sir John Lubbock's "Origin of Civilisation." Translation of Captain Noble's lecture delivered at the Royal Institution on the Explosive Force of Gunpowder. Report of the meeting of the Congress of German Naturalists and Physicians at Rostock in Sept. 1871, department of Geography and Chemistry.—In No. 44 is a history of the Observatory of Paris. Biography of M. Pictet by Soret. We have besides in each number abstracts of the proceedings of the various scientific societies: the Académie des Sciences, Académie de Médecine, Société de Biologie, Société Chimique, Société Géologique, Société Botanique, Société d'Anthropologie, and of the foreign scientific societies at Vienna, Berlin, London, Palermo, &c.

THE *American Naturalist* for June does not contain so many original articles as usual. The longest is by Dr. R H. Ward, on "Students' Microscopes," with particulars of the relative advantages offered by the instruments furnished by different makers.—Mr. J. A. Allen continues his "Ornithological Notes from the West," discoursing this time on the birds of Colorado. —There are two interesting shorter articles: by Mr. B. Pickman Mann, on the "White Coffee-leaf Miner" (*Cemiostoma coffeellum*), so destructive to the coffee culture of Brazil, with a plate; and by Prof. Sanborn Tenney, on the Remarkable Simulation of Death presented by the Hibernation of the Jumping Mouse (*Jaculus Hudsonius*) of the Western States.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 13.—"Further Experiments on the Effect of Alcohol and Exercise on the Elimination of Nitrogen, and on the Pulse and Temperature of the Body." By E. A. Parkes, F.R.S.

1. The elimination of nitrogen during exercise was unaffected by brandy; and since the experiments led to the same result in the former series during comparative rest, it seems certain that in healthy men on uniform good diet alcohol does not interfere with the disintegration of nitrogenous tissues.

2. The heat of the body, as judged of by the axilla and rectum temperatures, was unaffected by the amount given.

3. The pulse was increased in frequency by four ounces of brandy, and palpitation and breathlessness were brought on by larger doses, to such an extent as to greatly lessen the amount of work the man could do, and to render quick movements impossible. As the effect of labour alone is to augment the strength and frequency of the heart's action, it would appear obviously improper to act on the heart still more by alcohol. In this effect on the heart, and through it on the lungs, is perhaps to be found the explanation of the trainer's rule, which prohibits alcohol during exertion. Whether in a heart exhausted by exertion alcohol would be good or bad is not shown by these experiments; but it can hardly be supposed that to urge a heart which requires rest, as would then be the case, can be proper.

4. It seems clear, from the suddenness with which marked narcotic symptoms came on after the third dose was taken on each day, that the eight hours from 10 to 6 o'clock were not sufficient to get rid of the brandy taken at 10 and 2, and that in fact the body must have been still saturated at 6 o'clock.

The exact amount of brandy which commenced to lessen the labour the man could perform is not shown by these observations, and would require more careful modes of investigation. It was evidently some quantity more than 4 ounces which produced effects sufficiently marked to attract his attention, but I should not wish to affirm that every 4 ounces produced no effect in this direction. The man himself was of opinion that 4 ounces had no influence either way. He was quite certain it did not aid his work, but he could not see that it injured it. The second 4 ounces decidedly produced a bad effect.

5. That neither exercise on water nor on alcohol produced any effect on the phosphoric acid of the urine. The result is in accordance with that of the experiments recorded in No. 89 of the "Proceedings of the Royal Society."

The effect on the free acidity of the urine was also inappreciable. The free acidity may have been a little increased in the brandy period, but the change is so slight as to fall within the limits of normal variation.

The effect on the chlorine was not certain, as its ingress was not sufficiently constant.

As the action of alcohol in dietetic doses on the elimination of nitrogen and on the bodily temperature is so entirely negative, it seems reasonable to doubt if alcohol can have the depressing effect on the excretion of pulmonary carbon which is commonly attributed to it. It can hardly depress, one would think, the metamorphosis of tissues, or substances furnishing carbon, without affecting either the changes of the nitrogenous structures or bodily heat. It seems most important that fresh experiments should be made with respect to its effect on carbon elimination, as without a perfect knowledge on that point the use of alcohol as an article of diet in health cannot be fairly discussed.

Royal Geographical Society, June 10.—Major-General Sir Henry C. Rawlinson, president, in the chair. "On the New Hebrides and Santa Cruz Islands in the South-west Pacific," by Lieut. A. H. Markham. The paper described the topography, volcanic phenomena, and ethnology of these groups of islands, visited by him during the cruise of H.M.S. *Rosario*, under his command, between October 1871, and February 1872. He gave a history of the progress of discovery in this part of the Pacific, commencing from the voyage of Mendaña in 1568. All the various expeditions for three centuries did little more than sail through the groups and have deadly encounters with the natives. The islands lie in N.N.W. and S.S.E. direction, and contain some of the most continuously active volcanoes on the surface of the globe. The volcanic cones may be traced in a linear direction for 600 miles. The islands are remarkable for the absence of coral reefs around them, which is attributed by Dana to the destruction of the zoophytes by the heat produced by submarine

eruptions. Lieut. Markham ascended the volcano Gasowa, in the island of Tanna, and watched an eruption from the edge of the crater. During the intervals between the explosions (sounding like broadsides from a line-of-battle ship) the sheets of liquid fire seemed to flow back to three distant openings in the bottom of the funnel-shaped crater; masses of scoriæ were hurled up vertically to a height of 1,000 feet. The Melanesian (black, curly-haired) and Polynesian (straight-haired) races appeared to be curiously dovetailed in their distribution throughout the northern portion of these archipelagos. This was explained, in the discussion which followed, by the Bishop of Lichfield, who gave to the meeting a most interesting account of his own experiences in these islands, and who showed that the wandering Polynesians, who peopled the greater portion of the Pacific area (including New Zealand), had been driven in their canoes by winds on some of the smaller islands of the group.

Geological Society, June 5.—J. Gwyn Jeffreys, F.R.S., in the chair.—1. "Notes on Sand-pits, Mud-volcanoes, and Brine-pits, met with during the Yarkand Expedition of 1870." By Dr. George Henderson. The author described some very remarkable circular pits which occurred chiefly in the valley of the Karakash river. These pits varied in diameter from six to eight feet, and were between two and three feet deep, the distances between the pits being about the same as the diameters. He accounted for the formation of the pits by supposing that the water, which sinks into the gravel at the head of the valley, flows under a stratum of clay, which prevents it from rising; the water in course of time, however, flowing in very varying quantities at different periods, gradually washes away small portions of the clayey band, when the sand above runs through into the cavity thus formed, leaving the pits described by the author. The mud-volcanoes at Tarl Dab he accounted for by supposing that after a fall of rain or snow the air contained in the water-bearing stratum would get churned up with water and mud, and be ejected as a frothy mud, sometimes to a height of 3 ft.; while the brine-pits in the Karakash valley he believed to be formed by the excessive rise and fall in the level of that river at various times, which alternately fills and empties the bottoms of the pits, and the water left in the pits gets gradually concentrated by evaporation until a strong brine remains. Mr. Prestwich pointed out that the pits seemed due to quite another cause than the pipes in the chalk and other calcareous rocks, as they did not appear to arise from erosion by carbonic acid. Mr. Thorp suggested an analogy between the phenomena in Yarkand and those at Nantwich, and thought that the pits might be due to solution of rock-salt below the surface.—2. "On the Cervidæ of the Forest-bed of Norfolk and Suffolk," by W. Boyd Dawkins, F.R.S. The author described a new form of *Cervus* from the Forest-bed of Norfolk, which he based on a series of antlers, and named *C. verticornis*. The base of the antler is set on the head very obliquely; immediately above it springs the cylindrical brow-tyne, which suddenly curves downwards and inwards; immediately above the brow-tyne the beam is more or less cylindrical, becoming gradually flattened. A third flattened tyne springs on the anterior side of the beam, and immediately above it the broad crown terminated in two or more points. No tyne is thrown off on the posterior side of the antler, and the sweep is uninterrupted from the antler base to the first point of the crown. The antlers differ in curvature and otherwise from those of *Cervus megaceros*, but there is a general resemblance between the two animals; and the *verticornis* must have rivalled the Irish elk in size. A second species of deer, the *Cervus carnutorum*, which had been furnished by the strata of St. Prest near Chartres, must be added to the fauna of the forest-bed. The Cervidæ of the forest-bed present a remarkable mixture of forms such as the *Cervus polignacus*, *C. Sedgwickii*, *C. megaceros*, *C. carnutorum*, *C. elaphus*, and *C. capreolus*, seeming to indicate that in classification the forest-bed belongs rather to an early stage of the Pleistocene than to the Pliocene age. This inference is strongly corroborated by the presenee of the mammoth, which is so charactsristic of the Pleistocene age.—3. "The Classification of the Pleistocene Strata of Britain and the Continent by means of the Mammalia." By W. Boyd Dawkins, F.R.S. The Pleistocene deposits may be divided into three groups—1st, that in which the Pleistocene immigrants lived, with some of the southern and Pliocene animals in Britain, France, and Germany, and in which no arctic mammalia had arrived; 2nd, that in which the characteristic Pliocene Cervidæ had disappeared, and the *Elephas meridionalis* and *Rhinoceros etruscus* had been driven south; 3rd, that in which the true arctic mammalia were the chief inhabitants. This third, or late Pleistocene division, must be far older than any prehistoric deposits, as the latter often rest on the former, and are composed of different materials; but the difference offered by the fauna is the most striking. In the Pleistocene river-deposits twenty-eight species have been found, the remains of man being associated with the lion, hippopotamus, mammoth, wolf, and reindeer. On examining the fauna from the ossiferous caves, we find the same group of animals, with the exception of the musk-sheep; and it is therefore evident that the cave-fauna is identical with that or the river strata, and must be referred to the same period. Some few animals, however, which would naturally haunt caves, are peculiar to them, as the cave-bear, wild cat, leopard, &c. The magnitude of the break in time between the prehistoric and late Pleistocene period may be gathered also from the disappearance in the interval of no less than nineteen species. The middle division of the Pleistocene mammalia, or that from which the Pliocene Cervidæ had disappeared, and been replaced by invading temperate forms, is represented in Great Britain by the deposits of the Lower Brick-earths of the Thames Valley, and the older deposits in Kent's Hole and Oreston. The discovery, by the Rev. O. Fisher, of a flint-flake in the undisturbed Lower Brick-earth at Crayford, proves that man must have been living at this time. The mammalia from these deposits are linked to the Pliocene by the *Rh. megarhinus*, and to the late Pleistocene by the *Ovibos moschatus*. The presence of *Machærodus latidens* in Kent's Hole, and of the *Rh. megarhinus* in the cave at Oreston, tends to the conclusion that some of the caves in the south of England contain a fauna that was living before the late Pleistocene age. The whole assemblage of Pleistocene animals evinces a less severe climate than in the late Pleistocene times. The fossil bones from the forest-bed of Norfolk and Suffolk show that in the early Pleistocene mammalia there was a great mixture of Pleistocene and Pliocene species. It is probable also that the period was one of long duration, for in it we find two animals which are unknown on the Continent, implying that the lapse of time was sufficiently great to allow of the evolution of forms of animal life hitherto unknown, and which disappeared before the middle and late Pleistocene stages. The author criticised M. Lartet's classification of the late Pleistocene or Quaternary period by means of the cave-bear, mammoth, reindeer, and aurochs, and urged that, since the remains of all these animals were intimately associated in the caves of France, Germany, and Britain, and, so far as we know, the first two appeared and disappeared together, and the last two lived on into the Prehistoric age, they did not afford a basis for a chronology. The latest of the three divisions of the British Pleistocene fauna is widely spread through France, Germany, and Russia, from the English Channel to the shores of the Mediterranean. The Middle Pleistocene is represented by a river-deposit in Auvergne, and by a cave in the Jura, in which the presence of the *Machærodus latidens*, and a non-tichorine rhinoceros, and the absence of the characteristic arctic group of the late Pleistocene and of all the peculiar animals of the early Forest-bed stage, prove that that era must be Middle Pleistocene. The early Pleistocene division is represented in France by the river-deposit at Chartres, being characterised by the presence of two non-Pliocene animals, *Trogontherium* and *Cervus carnutorum*. The Pleistocene mammalia of the regions south of the Alps and Pyrenees present no trace of arctic species, the mammoth being viewed as an animal fitted for the climatal conditions both of Northern Siberia and of the Southern States of America. It contains *Elephas africanus* and *Hyæna striata*. The fauna of Sicily, Malta, and Crete differ considerably from that described above, possessing some peculiar forms, such as *Hippopotamus pentlandi*, *Myoxus melitensis*, and *Elephas melitensis*. The Pleistocene mammalia may be divided into five groups, each marking a difference in the climate, the first embracing those which now live in hot countries; the second those which inhabit northern regions, or high mountains, where the cold is severe; the third those which inhabit temperate region; a fourth those which are found alike in hot and cold; and a fifth which are extinct. There were three climatal zones, marked by the varying range of animals. The northern, into which the southern forms never penetrated, the latitude of Yorkshire being the boundary of the advance of the southern animals; the southern, into which the northern species never passed, a line passing through the Alps and Pyrenees being the limit of the range of the northern animals, and an intermediate area in which the two are found mingled together. Two out of the three zones are proved by the physical evidence of the Pleistocene strata.

We see by the discoveries of Dr. Bryce, Mr. Jameson, and others that the Pleistocene mammalia must have invaded Europe during the first Glacial period before the submergence, for the reindeer and the mammoth have been found in Scotland under the deposits of Boulder-clay. Dr. Falconer and others have also discovered the latter animal in the preglacial forest-bed. The Glacial period can therefore no longer be looked on as a hard and fast barrier separating one fauna from another. If man be treated as a Pleistocene animal, there is reason to believe that he formed one of the North Asiatic group, which was certainly in possession of Northern and Central Europe in Pre-glacial times. The Pleistocene mammalia may again be divided into three groups, those which came from Northern and Central Asia, those from Africa, and those which were living in the same area in the Pliocene age. Had not the animals which lived in Europe during the Pliocene age been insulated from those which invaded Europe from Asia by some impassable barrier, the latter would occur in our Pliocene strata as well as the former. Such a barrier is offered by the northern extension of the Caspian up the valley of the Obi to the Arctic Sea. The animals of Northern and Central Asia could not pass westwards until the barrier was removed by the elevation of the sea-bottom between the Caspian and the Urals. The same argument holds good as to the African mammalia, which could not have passed into Sicily, Spain, or Britain, without a northward extension of the African mainland. The relation of the Pleistocene to the Pliocene fauna is a question of great difficulty. If the Pliocene fauna be compared with that of the Forest-bed, it will be seen that the difference between them is very great. The Pliocene mastodon and tapir, and most of the Cervidæ, are replaced by forms such as the roe and red-deer, unknown until then; but many of the Pliocene animals were able to hold their ground against the Pleistocene invaders, although they were ultimately beaten in the struggle for existence by the new comers. The fauna which the author adopted as typically Pliocene is that furnished by the lacustrine strata of Auvergne, the marine sands of Montpellier, and the older fluviatile strata of the Val d'Arno. Mr. Prestwich was hardly prepared to accept the proposed division of the Pleistocene mammalia into three groups; at all events so far as Britain is concerned. Neither could he draw that distinction between the beds at Erith and Grays and those higher up the Thames, which found favour with the author. The barrier offered by the river itself might to some extent account for the absence of reindeer; and though there was a difference in the fauna in the two cases, it seemed hardly enough to mark any great distinction in time. As to the hippopotamus, which occurred over the whole of Northern Europe, associated with the musk-ox and large boulders, he could not see how the conclusion was to be escaped of its having been able to withstand greater cold than its present representative. Though the winters might have been colder, there was evidence in favour of the summers having been warmer; and the flora seems to have been much like that of the present day. The probable migrations of the different animal groups had already been pointed out by M. Lartet, though Mr. Dawkins had carried his investigation of the subject further. He called attention to the fact of the mammoth having been found in Italy. Mr. Boyd Dawkins, in reply, stated that in forming his conclusions, he had not left out of view the evidence afforded by the classes of remains other than those of mammalia, but they threw no light on the classification. With regard to the middle of his divisions of the Pleistocene mammalia, he relied to a great extent on the presence of *Rhinoceros megarhinus*, and of a large number of stags, to say nothing of the absence of reindeer. He did not attach so much importance to the question of the level, as such discrepancies as those pointed out appeared to him by no means impossible. He gave his reasons for not regarding the mammoth as an exclusively arctic animal. His remarks with regard to M. Lartet's classification referred rather to the expanded views of his followers than to those of M. Lartet himself. He acknowledged his obligations to Profs. Gaudry, Fraas, Rütimeyer, and Nilsson for various facts of which he had made use.

Paris

Academy of Sciences, June 10.—M. Marie presented a memoir on the determination of the critical point at which the region of convergence of Taylor's series is situated; and M. A. Ribaucour a note on the theory of lines of curvature.—M. Yvon Villarceau exhibited and described to the meeting an isochronous regulator with vanes, constructed by M. Breguet.—A note was read by M. E. Vial on a new mode of printing on stuffs by means of metallic precipitations, in which the author described a method of printing either by means of clichés or of copper or steel plates upon any textile fabric by the agency of nitrate of silver.—M. A. Clermont presented a note on the metallic trichloracetates, in which he described the preparation and characters of trichloracetate of ammonium, and of acid and neutral trichloracetate of thallium, and noticed the action of permanganate of potash upon hydrate of chloral in producing trichloracetic acid.—M. Wurtz communicated a note by M. Oré on M. O. Liebreich's experiments, from which the latter inferred that strychnine is an antidote to chloral. M. Oré shows grounds for the belief that M. Liebreich's experiments were inconclusive.—M. de Vibraye presented some further remarks on the spontaneous appearance in France of exotic plants in the track of the belligerent armies in the late war, in which he stated that the number of these plants introduced into the department of the Loir et Cher alone is 163.—In consequence of M. de Vibraye's statements, the sections of Botany and Rural Economy were instructed to prepare a scheme for the systematic introduction of Algerian forage plants suitable for the climate of France.—M. Decaisne presented a note by M. J. E. Planchon on the geographical distribution of the Ulmideæ.

THE TIDES AND THE TREASURY

OUR readers may have heard that England is a "sea-girt isle," and that we are a maritime nation, possessing a very powerful navy and an extensive commerce. They also know that the ocean to which we owe these peculiarities is a very restless fluid, its surface being ruffled by the wind, and its entire mass uplifted and depressed from time to time, in what we call tides, by the attractive power of the sun and moon. They know, too, that the theory of the tides has been investigated by the most profound mathematicians, particularly by Laplace, Lubbock, Airy, and Whewell. And they are, no doubt, aware that the theoretical laws deduced by these learned men, though indispensable as a foundation of our knowledge, are entirely insufficient, by themselves, for the wants of man, the conformation of the coast-line and of the sea bottom powerfully modifying tidal facts. Hence it becomes necessary to resort to observations and surveys in order to know what will be the course of the tides as to heights and times in particular localities frequented by ships, such as roadsteads, harbours, and the mouths of rivers. All this, perhaps, every one of our readers knows; but it may not, perhaps, be so generally known that the study of the tides throws light on various high cosmical, gravitational, and physico-geographical problems.

The importance of this study is unquestionable, and, indeed, unquestioned; and it has been pursued to a limited extent by ourselves and all civilised nations at the public cost. But as yet the observations have been insufficient both as to character and as to the number of localities at which they have been taken, and also as to the reduction of them, and the deductions from them, that have been made.

Sir William Thomson accordingly brought the subject before the British Association, and obtained from that body the aid of a Committee and of small sums of money from year to year, to enable him to supply, so far as might be possible, these deficiencies. The Committee was designated "for the purpose of promoting the extension, improvement, and harmonic analysis of tidal observations;" and, having regard to the object with which we now address the scientific public, we must also give its composition, namely, Sir W. Thomson, Prof. J. C. Adams, the Astronomer Royal, Mr. J. F. Bateman, C.E., Admiral Sir E. Belcher, Mr. T. G. Bunt, Staff-Commander Burwood, R.N., Mr. Warren De La Rue, Prof. Fischer, Mr. J. P. Gassiot, Prof. Haughton, Mr. J. R. Hind, Prof. Kelland, Staff-Captain Moriarty, Mr. J. Oldham, C.E., Mr. W. Parkes, C.E., Prof. Bartholomew Price, Prof. Rev. C. Pritchard, Prof. Rankine, Captain Richards, Hydrographer to the Navy, Dr. Robinson, Sir E. Sabine, Mr. W. Sissons, Prof. Stokes, General Strachey, Mr. T. Webster, Profs. Fuller and Iselin (secretaries), and Sir W. Thomson (reporter). Every gentleman here named is favourably known, and the majority are highly distinguished, in those branches of the sciences with which the tides are connected.

The Committee has made three reports, namely, in 1868, 1870, and 1871, the two first prepared by Sir W. Thomson, and the third by Mr. E. Roberts of the Nautical Alliance Office, under whose able superintendence the computations and deductions were placed. The three reports have been published *in extenso* by the British Association in the volumes of the above-mentioned years. They bring fully under view the theoretical basis of the investigation, an account of observations made by the Committee and by the authorities, some of the conclusions deduced therefrom, and a statement of the measures recommended in order to extend and perfect our knowledge of the subject. It is impossible to exaggerate the value of these documents. They clearly define the present position of the problem, and the course which any future researches must take.

At the meeting of the Council of the Association on on November 11, 1871, the following resolutions were passed:—

> (1.) That it is desirable that the British Association apply to the Treasury for funds to enable the Tidal Committee to continue their calculations and observations.
>
> (2.) That it is desirable that the British Association should urge upon the Government of India the importance for navigation and other practical purposes and for science, of making accurate and continued observations on the tides at several points on the Coast of India.

The second of these resolutions has already been productive of fruit. Colonel Walker, R.E., the distinguished superintendent of the Great Trigonometrical Survey of India, has, under the authority of the Indian Government, established self-registering tide-gauges at several points in India, and has made adequate arrangements for the reduction of the results.

It is with Resolution (1) that we are concerned to-day, the official correspondence relating to it having been placed at our disposal for review. This consists of only two documents—a Memorial of the British Association to the Lords of the Treasury, signed by the President, and dated May 21, 1872; and the reply thereto.

The main points dwelt on in the memorial may be thus summarised:—That the primary object which the Committee have uniformly kept in view is "the practical application of their results to Physical Geography, Meteorology, Coast and Harbour Engineering, and Navigation;" that they have undertaken the reduction of twenty years' observations made with self-registering tide-gauges—"a most laborious work;" that 600*l.* has been granted by the British Association in four successive annual sums of 100*l.* and one of 200*l.*, "to pay the calculators, and to print and prepare tables, forms for calculations, &c.; that the last grant barely sufficed for the work actually in hand;" and that they now apply to the Government for the sum of 150*l.*, "to secure the continuance of the investigation."

The reply to this memorial is such that, unless printed *in extenso*, many persons would, we feel certain, refuse to believe that such a document could have been issued with the sanction of a civilised Government. We therefore now append it:—

"Treasury Chambers, June 3, 1872

"Sir,—The Chancellor of the Exchequer has referred to the Lords Commissioners of Her Majesty's Treasury the memorial of the British Association for the Advancement of Science, forwarded to him with your letter of the 21st ult., praying for Government assistance in connection with tidal observations.

"I am to state that their Lordships have given their anxious attention to the memorial, and that they are fully sensible of the interesting nature of such investigations; but that they feel that if they acceded to this request it would be impossible to refuse to contribute towards the numerous other objects which men of eminence may desire to treat scientifically.

"Their Lordships must, therefore, though with regret, decline to make a promise of assistance towards the present object out of public funds.

"I am, Sir, your obedient servant,

"(Signed) WILLIAM LAW

"Sir W. Thomson, Athenæum Club."

Nothing would be easier than to be sarcastically indignant on such a theme as this. The picture of the Lords Commissioners of H M. Treasury giving their "anxious attention" to the tides, and expressing "regret" that they cannot grant so large a sum as 150*l*. for investigations which they really think "interesting," lest eminent men should avail themselves of so imprudent a precedent, in order to make further demands for "scientifically" treating other objects of the same character—this picture is one which requires but a touch, it hardly, indeed, needs a touch, to make it a far-fetched caricature of civilised governing.

To apply the lash, however, to narrow stupidity, can only gratify temporary spleen; and we must resist the temptation in order to attain the higher object of illustrating, by this pointed example, the present condition of State science in England, and of showing what we require in order to prevent the mischief which its existing condition must cause.

To begin with the British Association. Here is a body carrying on operations by means of privately contributed funds, of very limited amount, about 2,000*l*. a year; not for the first, tenth, or hundredth time, quietly accepting as a fact that certain scientific objects of national importance will not be recognised or pursued by the Government, and, therefore, stepping in to contribute as far as they can towards their accomplishment. The Kew Observatory, the map of the moon, the utilisation of sewage, are other examples of the same kind. They have all been commenced on a necessarily miserable scale—a little advance has been made, and then the thing has dropped through for want of funds. Now, according to our apprehension the British Association, though acting with the very best intentions and motives, have greatly erred in these matters. It is absurd to suppose that any one of the numerous large national scientific problems they have taken up could be properly dealt with even if their whole income of 2,000*l*. a year had been devoted exclusively to it. The small contributions to each which they have been able to afford, if not sometimes quite wasted, have almost invariably produced results quite inadequate even to the small expenditure, simply because it was so small as to forbid really efficient measures. This is an evil, but as some good results, however slight and imperfect, have been achieved, it might be submitted to if it were all. A far greater evil, however, has been caused by the measures we allude to. An obscurity has been thrown round the great question which England must soon solve. "What is the scientific work which the Government is bound to perform for the benefit of the community at large; and what is the scientific work which cannot be performed by State agency so well as by private enterprise?"

So long as individuals, and bodies of individuals, without discrimination, attempt to do what should properly devolve on the State, so long will a Government, destitute, like ours, of a particle of the scientific element, neglect its legitimate duties. We therefore strongly counsel the British Association, at their next meeting, to take measures for classifying science under the two great heads of Public and Private, to supply the Government with a full statement of all comprehended under the first head, and to refuse a single penny of its funds to any object not distinctly appertaining to the second. This will bring matters to a crisis—and we want a crisis.

As to the Government, what can we say? Poor Mr. Law's letter speaks volumes. It plaintively confesses its total inability to grasp any State scientific problem lest it should have to deal with all. We have no heart to spurn a prostrate form so lowly and humble; but can we not raise it? Can we not introduce into our Administration a source of knowledge on which they can rely to guide them in the choice of scientific objects really profitable to the nation, and officials able to insure a proper system for the attainment of such objects?

Many minds are busy on this very question; and the fact that a maritime Government will not give 150*l*. towards investigating the tides is not likely to weaken their determination to bring it to a decisive issue.

PUBLIC HEALTH IN AMERICA

Third Annual Report of the State Board of Health of Massachusetts. (Jan. 1872.)

PUBLIC health problems in New England are very much of the same character as they are in Old England. The countries and climates are both healthy, and there is plenty of preventible disease notwithstanding. In both countries bad habits have much to do with the causation of disease. In both countries civilisation takes but small account of natural laws, and as a consequence makes one step forwards where two might be made. One reason of this is partly want of knowledge, but the report before us shows that another not unimportant cause is attempting to gain present advantages by discounting the future. It is an old story told in a new country. There is a small present profit to a small minority of the community, at the cost of the remainder; but Nature, as has been well said, "just goes on levying her own cess in her own way," *i.e.*, she sends in her account, not only to the perpetrators of the damage, but to the whole community which tacitly submits to it.

The Report consists of two portions, one part giving a brief account of the Board's proceedings, the other containing an interesting series of reports by different writers on the effects of arsenical colours on health, on mill dams and water obstructions as causes of disease, on the use and abuse of intoxicating drinks, with reference to a cosmic law of intemperance, on provision for the insane,

on the use and abuse of opium. There is a curious paper on the effects on health of the use of the feet in working sewing machines. There are others on slaughtering and bone boiling, vegetable parasites and the diseases produced by them, on small-pox, and on health of towns generally, with special reference to the occurrence of typhoid fever.

Our space will only admit of a cursory glance at the chief questions dealt with in these papers as illustrations of the discounting process alluded to.

Somebody, for example, discovers that papers coloured with arsenic are fair to look on, and may possibly become a source of profit. He makes such papers, and people hang their rooms with them. The maker flourishes, and the purchasers find to their cost that they are poisoned; but not always. If they were always poisoned they would cease to buy, but this not being the case, the law assumes the manufacture to be legitimate, and people take their chance.

The State of Massachusetts was in former times almost entirely exempted from intermittent and remittent fevers. But, unfortunately, the State has numerous "water privileges," which an industrious people may take advantage of. They erect dams and backwater large areas of land, many of which became built on, and now Massachusetts has its fair quota of periodic fevers passing into typhoid fever when the streams dry up in summer.

We next approach the *pons asinorum* of social legislation, viz., the drink traffic, which we, in this country, appear disposed to deal with by reversing the principles of political economy, which teach that demand will ensure supply. We, on the contrary, propose to cut short the supply in hope that the demand may become less in consequence. In a report on this subject, the Chairman of the Board, Mr. Bowditch, endeavours to raise intemperance causes to the dignity of a science, but then he also states that "open dram shops are an unmitigated evil." Whoever wishes to master the question of intoxicating drinks, and to learn something of the cost to a community at which the profit of vending them is purchased, will find much to instruct him in this report. The remedies suggested are shutting up drunkards until they are cured, and using beer and wine instead of spirits. Might we suggest for the consideration of our Transatlantic cousins and also of our own national temperance societies, that the amounts of crime, lunacy, and pauperism produced by drink are possibly ascertainable quantities, and that while we charge railway casualties on companies under whose administration they occur, we charge the costs of crime, lunacy, and pauperism, not on the parties who, for their own profit, are accessory to their production, but on the public at large. If we do the one why do we do the other? Why should railway shareholders be made to refund part of their profits, and publicans be allowed to pocket all theirs? And may not the cure for drunkenness be found after all in leaving supply and demand to themselves, and charging all the damage accruing to the State on the liquor retailers? Might not such a course help to reduce rates and taxes, and convert the publicans into an efficient unpaid police? At all events, it is worth while to ask these questions.

Another kindred subject is the abuse of opium. It appears that the domestic consumption of opium in the United States has increased tenfold in thirty years, for a population little more than doubled. We are sorry to say that teetotalism is blamed for this result. The reporter states that in countries where vine culture prevails drunkenness and opium eating are comparatively unknown, and he argues in favour of domestic wine manufacture as a remedy for both evils.

We learn from the paper on sewing machines, that while making a shirt requires 14 hours 26 minutes by hand, it can be put together by the machine in 1 hour and 16 minutes. A coat requires 16 hours and 35 minutes hand sewing, and only 2 hours 38 minutes by machine sewing. A silk dress can be made by machine in 1 hour 13 minutes, but requires 8 hours 27 minutes of hand labour. The work is mainly done by the feet acting on treadles, which, if imperfectly applied, make a great call on certain sets only of muscles and nerves, and the result is a development of various nervous and constitutional affections peculiar to the female sex.

The best remedy is, of course, applying a motive power to the machine, and next to this to do away with the heel and toe movement of the treadle, and to substitute a swinging backward and forward movement of the feet and legs, or by other improved adaptations of leverage.

The only other paper we can notice is the one on the effect of vegetable parasites on man, which contains a good digest of the present state of knowledge on the subject. The moral of the paper is that, if people will keep their skins dirty and thus allow their vitality to fall below par, nature will kindly step in and supply fungal spores to convert the dirt into some product which is sure to call attention to the fact.

It appears that Boston young men are apt to contract a peculiar kind of ringworm by being shaved in barber's shops, the cure for which is, of course, to learn to shave themselves at home.

These Reports will do much good by enlightening public opinion, and so leading to better habits of life and to greater consideration of the interests of others, while people are looking after their own interests, results which there is small chance of arriving at by any mere legislative enactments.

OUR BOOK SHELF

Note sur les Singes fossils trouvés en Italie, précédé d'un aperçu sur les quadrumanes fossiles en général. Forsyth Major, M.D. (Reprinted from the Proceedings of the Italian Society of Natural Sciences.)

THE primary object of this paper, which was read last month, was to describe certain fossil Simian remains which have lately for the first time been discovered in Italy. One which was found in the valley of the Arno, and presented by the Marquis Ermes-Visconti to the Museum of the city of Milan, consisted of a fragment of a maxilla with the last three molars. It is referred by the writer to a species closely related to the Barbary ape (*Macacus inuus*, Linn.), still found at Gibraltar. It appears to have been somewhat smaller than the *M. priscus* of Montpellier, described by Gervais. A second fossil, part of a mandible, belonging to the same species, has been found by M. Cocchi in the Upper Arno valley. A third, also a mandible and also discovered in Tuscany, at Monte Bamboli, has

been assigned by the last-named zoologist to a species of *Cercopithecus*. Lastly, some Simian teeth from Mugello, now in the museum of Pisa, are supposed by Dr. Major to belong to a species of *Macacus*.

After discussing the characters of the soil in which the first of these fossils was found, and the other mammalian remains of the same formation—*Rhinocerus Etruscus*, *R. leptorrhinus*, *R. hemitocchus* (Falconer), *Elephas meridionalis*, *Hippopotamus major*(?), *Bos Etruscus*, *Mastodon Arvernensis*, the last being probably somewhat earlier—the author concludes that the maxilla above mentioned belongs to the later Pliocene period.

The following is a list of fossil quadrumana as yet discovered :—

EOCENE

1839 Lyell and Owen, *Eopithecus*(?), Woodbridge, Suffolk.
1862 Rubimeyer, *Cænopithecus lemuroides*, Swiss Jura.

MIOCENE

1836 Cantley and Falconer, *Semnopithecus* sp., Sewalik, N.W. India.
1836 Baker and Durand, *Semnopithecus* sp., Sewalik, N.W. India.
1837 Cantley and Falconer, *Semnopithecus* sp., Sewalik, N.W. India.
1837 Cantley and Falconer, *Macacus erythræus v. rhesus*, Sewalik, N.W. India.
1837 Cantley and Falconer, *Pithecia* sp., Sewalik, N.W. India.
1837 Lartet, *Pliopithecus*, S. of France.
1856 Lartet, *Dryopithecus Fontani*, S. of France.
1863 Biedermann and Heer, *Pliopithecus platyodon*, Zurich.
1870 Fraas, *Colobus grandævus*, Würtemberg.
1862 Gacedry, *Mesopithecus Pentelici*, Greece.

PLIOCENE AND QUATERNARY

1836 Lund, *Propithecus, Iacchus, Callithrix, Cebus*, Brazil.*
1845 V. Claussen, *Mycetes*(?) Brazil.
1845 Owen, *Macacus pliocænus*, Gray's Thurrock, Essex.
1859 Gervais, *Semnopithecus Monspessulanus*, Montpellier.
1859 Gervais, *Macacus priscus*, Montpellier.
1871 Gervais, *Cercopithecus*, Monte Bamboli.
1872 F. Major, *Macacus inuus*(?) Valley of the Arno.

From the restricted geographical distribution of the *Lemuridæ*, it is not surprising that no remains of this suborder have yet been discovered. The fossil monkeys as yet found in S. America belong to the *Hapalidæ* or *Platyrrhini*, still peculiar to the Neotropical region. All the rest belong to the *Catarrhini*, and some to the anthropomorphous genera. They all belong to the old world, but while some have been found in India, others inhabited Greece, France, Germany, and England.

P. S.

* Ann. Nat. Hist., vol. iii. p. 426.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Total Eclipse in Java

[Extracted from a letter from Prof. Oudemans by Mr. J. N. Lockyer.]

I WAS not fortunate on the occasion of this eclipse. I had a spectroscope of Merz, sent by the Minister of the Colonies on the advice of the Academy of Sciences at Amsterdam ; but the telescope to which it was to be adapted had no clock-motion. I took it with me to the Island Lawoengan in the Pepperbay, whither a Government steamer brought me and three other gentlemen. On the day of the eclipse we had three showers before totality, sky wholly overcast ; but now and then the sun broke through between the clouds. Happily the clouds opened just before totality. My observations were therefore confined, like that of the other gentlemen of my party, to the general observations, following therein principally the suggestions and indications published in NATURE. I have already sent the results to the Academy at Amsterdam ; and take the liberty of offering you herewith a copy of the general report, which I made up from the several partial ones for the Government.

My observations and those of my party have given me the conviction of the existence of an optical phenomenon, besides the purely solar phenomenon ; not of an atmospheric origin (there is no question whatever of this), but of rays, variable during the totality, too variable to attribute them to luminous solar matter emerging from the body of the sun itself. I could follow the rays and some rifts as far as the moon's limb.

At Bintensory, the residence of the Governor-General, they were more successful, the weather being beautiful ; there, as well as at Batavia, Mr. Bergsma caused observations of the declination of the magnet to be made during the whole morning, several days before, the day of, and several days after, the eclipse, at intervals of five minutes. The observations are now reduced for the influence of the moon, and he will propose to the Government to publish these observations and their reduction apart. The result of the observations is, that the movements of the magnet-needle during the eclipse have not deviated considerably from the common diurnal movement of the declination at this time of the year.

The "flying shadows" were very remarkable at Buitensorg, they were observed by persons wholly unacquainted with the phenomenon.

They were seen by Mr. Bergsma on a white wall directed E. 13° 30′ N. to W. 12° 30′ S., and on a sheet of white paper lying on a table. On the wall the shadows were inclined to the west, making with the horizontal line an angle according to one observer's measurement of 40°, and according to another's of 45°. They moved from E. to W. On the white paper they made an angle of 45° with the edges, which were perpendicular to the wall ; they moved on the paper from S.E. to N.W. The phenomenon did not show itself as it is represented in "Secchi's Le Soleil," p. 158.

The shadows had a breadth of 5 to 6 centimetres ; they were limited by lines with small irregular undulations ; they were separated by regularly illuminated bands ; the distance of the shadows was, according to Dr. Scheffer (the botanist), 1½ decimetres, and, according to Mr. Lang, about 3 decimetres or a foot. They moved parallel to themselves slowly ; their velocity over the wall was about that of a horse in a moderate trotting pace. Mr. Bergsma saw the shadows from about three minutes before totality.

During totality they were not visible according to Mr. Lang, whom Mr. Bergsma had requested to pay particular attention to this point, only Mr. Lang saw now and then a slight change in the intensity of the light on the paper.

Immediately after totality the shadows appeared again, increasing and diminishing alternatively in strength, but growing gradually less and less distinct, although Mr. Bergsma continued to see them till about 5 minutes after totality.

Mr. Bergsma now describes the means proper to obtain more reliable observations on future occasions.

By construction and calculation I have deduced from Mr. Bergsma's data as to the direction of the shadows on the wall and the paper the following :—

I assumed the inclination of the lines on the wall to be 42½° with respect to a horizontal line, taking the mean between the computations of Messrs. Lang and Scheffe. That the shadow-lines made an angle of 45° with the edges of the paper, could be understood on two different theories—viz., that their azimuth was 121½° and 211½° (N.E.) Mr. Bergsma declared that 211½ was meant.

Now, if we pass a plane through a shadow-line on the wall and its prolongation on the paper, this plane intersects the horizon along a line directed in an azimuth of 31½° (N.E.), whereas the same plane has an inclination of 52⅓° to the west.

The normal on this plane meets the sky in a point having an azimuth of 121½°, and an altitude of 37⅓. At the middle of totality the sun had an azimuth of 131·4, and an altitude of 54°. Accordingly there is a difference of 10° in azimuth, and 16° in altitude. As regards the rough computation of the direction of the shadow-lines, this error may easily have been made, the more

so as the observers were not prepared for an accurate observation of the phenomenon.

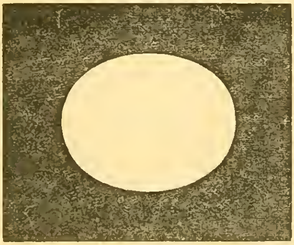
Thus it appears, without anticipating more accurate observations on the occasion of late eclipses, that the shadow-lines were situated in planes perpendicular to the sun's rays. They moved *from* the sun.

Singularly enough, neither at Tjilentap nor at the island Lawoengan, was anything of the phenomenon seen. At the island circumstances were very unfavourable, but at Tjilentap the sky was clear. OUDEMANS

Batavia, April 28

The Great Storm of June 18

OUT of a large quantity of hailstones collected here after the storm had subsided, and which were therefore partly melted, I selected one of the largest. The subjoined boundary line is the measure of a section of this hailstone through the poles, the



form of it being a prolate spheroid, flattened on two sides, like a confectionary lozenge, if I may employ so vulgar a comparison. Many of the hailstones, however, as they fell, were jagged pieces of ice, the like of which I have never seen.

Edgbaston, Birmingham, June 21 C. M. INGLEBY

Spectrum of Lightning

I HAD a good view of the spectra of lightning during the storm of yesterday. Frequently there was only one bright line visible, this being coincident with the nitrogen line. At other times there were several bright lines, sometimes with, and at other times without, the nitrogen line. Several flashes showed a continuous sprectrum without visible lines. My instrument was a small direct-vision spectroscope, but sufficiently powerful to divide the sodium line. J. P. JOULE

Broughton, Manchester, June 19

YESTERDAY this neighbourhood was visited by a most terrific thunderstorm, such as I have never before seen in England. Indeed, it is stated that the last storm of similar severity occurred exactly 33 years ago to a day—rather a singular coincidence. The storm commenced here about half-past one, though distant thunder was audible at one o'clock. It was accompanied by violent wind, rain, and hail, and lasted about an hour, during which 0 66 in. of rain fell. The wind was S.E. at the time, but the storm came from the W. The hailstones are described as being, many of them, larger than marbles, and did a good deal of damage to glass. Several fatal accidents have occurred from the lightning, which for some time was almost incessant. I examined its spectrum with a miniature spectroscope, and succeeded in observing four or five lines. Their approximate positions, which I give below, are very roughly determined, and especially so toward the red end. They were obtained by comparison with the Fraunhofer lines, and with the carbon spectrum of a Bunsen burner. The former were mostly very faint from the darkness, but the atmospheric absorption bands near D were very marked. I am strongly of opinion that the spectrum is that ordinarily given by a spark in air, but was unable to make direct comparison. I have since examined a feeble spark by the same spectroscope, and the general appearance is very similar. I also tried observation of the long zig-zag flashes with a simple prism, but without much success, though I was able to see the spectrum. H. R. PROCTER

Water Analysis

MY attention has been directed to an article entitled "Water Analysis, I." published in NATURE of June 6. The article is unsigned, bearing neither name nor initials, and contains strange errors and misrepresentations, some of which I beg permission to correct.

First, there is a false date. The article states that in 1868 "Messrs. Chapman, Wanklyn, and Smith proposed to determine the organic matter in water from the amonnt of ammonia evolved when the water was treated with a strongly alkaline solution of potassic permanganate, and then distilled." The truth is, that our paper, proposing the process, and giving directions how to work it, together with examples, was read before the Chemical Society on June 20, 1867, and published in the *Journal* for the year 1867 (*vide* p. 445, *et seq*). Moreover, in the year 1867, our process was extensively employed by the Rivers Commission by Mr. Way, who was at that period the chemist on the Commission.

Next, I have to notice a misrepresentation. The article describes us as having at first stated that albumen gave up the whole of its nitrogen (in the form of ammonia) when treated with alkaline permanganate, and that afterwards we said that only a certain fraction was obtainable in that way.

We have never said that distillation of albumen with alkaline permanganate converted the whole of the nitrogen of the albumen into ammonia. The assertion in the article is therefore untrue. The circumstance to which your statement was intended to refer was the following.

In our paper read on June 20, 1867, we proposed two distinct modifications of the water process. In the one modification we evaporated to dryness with potash in the oil-bath, and afterwards distilled the residue with alkaline permanganate. The quantity of ammonia got by the operation with potash in the oil-bath, *plus* the quantity of ammonia got afterwards by permanganate of potash, is equal or nearly equal to the total ammonia which the total nitrogen of the albumen will yield.

On June 20, 1867, in addition to this early form of the water process, we described and recommended a second modification, consisting in the omission of the evaporation to dryness with potash. We boiled with potash, but did not take down to dryness, and then boiled with permanganate. At that date we knew, and mentioned in the paper, that omission to take down to dryness involved some loss of ammonia which potash should evolve. We did not know that failure to get the full yield with potash involved the ultimate sacrifice of a certain quantity of ammonia. That fact was afterwards ascertained by me, and published later in the autumn of 1867, and is duly recorded in the *Journal of the Chemical Society*.

The conviction that a really serviceable process of water-analysis must be a simple one, and the perception that a definite fraction of the total nitrogen was as good a datum as the total nitrogen itself, led me to persist in recommending the second modification rather than the first. Much experience in these matters has confirmed my judgment, and I do not repent the choice that we made.

Returning to the article. After having mentioned our experiments on papaverine, sulphate of cinchonine, narcotine, strychnine, sulphate of quinine, there is the following extraordinary statement:—

"If the authors had enabled us to ascertain the absolute error on the quantity taken instead of the percentage error, by giving us the quantities from which the results were taken, it would no doubt be much more apparent: the results given above in the case of Frankland and Armstrong's paper are absolute errors."

I invite you to open the *Journal of the Chemical Society*, May 1868, which is referred to in our treatise. We did give the quantities from which the results were obtained. Quoting from our memoir, you may read that we took 10 mgrm. of papaverine, and obtained 0·22 mgrm. of ammonia; that we took 10 mgrm. and 5 mgrm. of sulphate of cinchonine, and got respectively 0·57 and

0·27 mgrm. of ammonia; that we took 5·5 mgrm. of strychnine and obtained 0·30 mgrm. of ammonia; and that we took 10 mgrm. of sulphate of quinine and obtained 0·45 mgrm. of ammonia.

The absolute errors, therefore, were—

	Milligrammes of ammonia. Calculated.	Found.	Error.
Papaverine	0·25	0·22	0·03
I. Sulphate of cinchonine	0·48	0·57	0·09
II. " "	0·24	0·27	0·03
Strychnine	0·28	0·30	0·02
Sulphate of quinine	0·456	0·45	0·006

giving a mean error of 0·035 mgrm.

I have to remark, in reference to these five examples, that they are not cases selected by me to exhibit the accuracy of our process, but cases picked out from a great number, in order to exhibit what takes place under the most unfavourable circumstances. In contrast with these are Frankland and Armstrong's six determinations, five on urea and one on hippuric acid, given by themselves as exemplifying the accuracy of their method, and showing a mean error of 0·35 mgrm. of nitrogen—just ten times as much as ours under the most unfavourable conditions.

I observe you say that the amount of ammonia obtainable from albumen by the action of alkaline permanganate is influenced by the degree of concentration of the solution, the amount of heat applied to the retort, and consequent rate of distillation, and the time to which the solution is exposed to the action of the alkaline permanganate.

It would be just as true and as much to the point to say that the amount of carbonic acid obtainable from sugar depended on the amount of oxide of copper with which it is mixed, and the length of time to which it is exposed to a red heat.

I am able to affirm most positively that there is no difference in the yield of ammonia from albumen, whether the solution be of a certain strength or six times as strong, or whether the distillation be rapid or slow; and in proof of this I refer to a set of experiments on albumen, published in 1867. If the action of the permanganate be pushed to the ultimate limit, the yield of ammonia is constant.

Your assertion that water which has been distilled from permanganate, and gives no reaction with the Nessler test, yields ammonia on being again distilled with permanganate, will not astonish persons who have had experience in the working of our process. The explanation of this fact is now, I believe, tolerably well understood, and is simply this: that when water contains so minute a quantity of ammonia as not to impart a colour when 100 cubic centimetres of it are treated with Nessler test, it may still contain sufficient ammonia to yield a perceptibly ammoniacal distillate if one litre be made to yield 100 cubic centimetres of distillate.

In conclusion, you mention some difficulties in applying our process to the effluent water from sewage farms. I will not, on this occasion, describe how these difficulties are overcome. Suffice it to say that they have been overcome by very simple and obvious means. J. ALFRED WANKLYN

11, Harrington Street, London, June 17

Parasite of the Beaver

MAY I occupy a few lines of your valuable space for a brief note upon the singular parasite of the beaver, *Platypsylla castoris* Ritsema (*Platypsyllus castorinus* Westwood)?

On the kind application of Messrs. Wayers and Roelofs, of Brussels, Mr. Ritsema very courteously presented me, some months ago, with a pair of this insect, the remarkable characters of which seem to deserve a more extended notice than has been given by himself or by Prof. Westwood, who almost at the same time described it from specimens obtained from a different source.

The former has classed it with the so-called suborder, *Suctoria*, or *Aphaniptera*, as a family or series equal in value to the *Pulicidæ* (fleas, jiggers, &c.), while the latter considered it so peculiar as to represent a new order of insects, which he named *Achreioptera*.

After a careful study of a series of beautiful dissections made for me by my friend the Rev. A. Matthews, I have to dissent from both of these views, and to regard it, in accordance with my impressions at first sight, as *Coleopterous*.

The appearance of the insect is such as to mark it, on the most superficial inspection, as a distinct family. In the wonderful structure of the mentum, with three immense posterior lobes, it shows an affinity, though remote, with the singular genus, *Leptinus*, which is also the type of a family (*vide* Le Conte, Proc. Acad. Nat. Sciences, Philadelphia, 1866, p. 368). But the lateral lobes in *Platypsylla*, broad triangular processes, are in *Leptinus* only narrow spines, projecting in the same manner over the gular plate.

In the form of the antennæ it resembles *Gyrinus* and *Parnus*, and in other less important parts of the body it has unmistakable affinities with various members of the Clavicorn series, such as *Staphylinidæ*, *Silphidæ*, and *Corylophidæ*, though especially with *Trichopterygidæ*, in the very extraordinary genus *Limulodes*, Matthews.

A very rare character is the reception of the antennæ in cavities on the dorsal surface of the prothorax; such characters are found in *Physemus* of the *Byrrhidæ*, *Mychocerus* Er., the affinities of which are doubtful, and in *Usechus* Motsch. of the *Tenebrionidæ*. In those three genera the antennal cavities are round fossæ, while in *Platypsylla* they are grooves extending along the whole lateral margin.

My object in the present note is not so much to express an opinion on the systematic position of this wonderful animal (which I will discuss fully in an illustrated memoir now in preparation), as to call the attention of your readers to the possible occurrence of similar epizoa on other aquatic mammals, especially rodents.

The complex affinities of this genus indicate that it either was in former times, or is at present, a widely distributed type. The European beaver, the capybara, and the musk rat, may, perhaps, when examined, be found to support allied forms.

I will conclude by observing that the insect has no organs with which to perforate the substance of its patron, and cannot eat living tissues or fluids; it is, therefore, not a parasite in the strict sense of the term, but an inquiline, living upon effete material, perhaps epidermal scales. The larva should be diligently sought for by those that have the opportunity, both in the houses and on the bodies of the beavers, as a knowledge of the development and transformations will be of importance in recognising more fully its affinities.

I trust that this note may stimulate further investigation on the part of some of your readers.

Lausanne, June 19 JOHN L. LE CONTE

Vespertilio

YESTERDAY a neighbour, in cutting down a very old, wide-spreading broadleaf (*Griselinia littoralis*), came suddenly on a great crowd of bats. Whilst he was chopping he noticed that his dog seized something, which he found to be a bat. From a huge hollow limb of the tree seventy-five bats were dislodged; they fluttered into the bush, keeping just above the ground.

Ohinitahi, New Zealand, Feb. 14 T. H. POTTS

Origin of Cyclones

I HAVE to thank Mr. Whitmee for his statement about the formation of cyclones at the Samoan and neighbouring islands in the latter part of the Southern summer. It will be seen that though I was ignorant of the fact when I wrote in my former letter on cyclones, it confirms my theory that they originate "in the meeting of the trade-winds in the northern and southern hemispheres, at some distance north or south of the equator." The cyclone region in which the Samoan and Fiji islands are situated is probably an extension of that of the Southern Indian Ocean. JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Co. Antrim, June 17

THE POPULATION OF THE PHILIPPINE ISLANDS

ACCORDING to the latest, not yet published, statistics, the Philippine Islands are inhabited by 7,451,352 inhabitants, distributed into 43 provinces and 933 cities or villages. 1,232,544 pay tribute to the Government, and the number of 7,451,352 is calculated on the supposition that about the sixth part of the whole has to pay tribute. As there exist in all the islands, even in Luzon, independent tribes,

and a large number in Mindanao, the number of 7,451,352 gives no correct idea of the real population of the Philippines. This is not known at all, and will not be known for a long time to come.

The number of 7,451,352 is composed in the following manner :—

The Island of Luzon	4,467,111	in	508	villages
,, ,, ,, Panay	1,052,586	,,	92	,,
,, ,, ,, Cebu	427,356	,,	51	,,
,, ,, ,, Leyte	285,495	,,	43	,,
,, ,, ,, Bohol	283,515	,,	36	,,
,, ,, ,, Negros	255,873	,,	43	,,
,, ,, ,, Samar	250,062	,,	35	,,
,, ,, ,, Mindanao	191,802	,,	64	,,
,, ,, ,, Mindoro	70,926	,,	18	,,

The remainder on the other small islands.

The following is the division into 43 provinces :—

Abra	37,266	in	8	villages
Albay	341,493	,,	38	,,
Antique	131,880	,,	19	,,
Basilan	600	,,	1	,,
Bataan	67,362	,,	12	,,
Batangas	432,504	,,	21	,,
Bulacan	346,317	,,	24	,,
Bohol	283,515	,,	36	,,
Burias	2,430	,,	1	,,

	7,451,352*		933	

The following division of the Philippine Islands is proposed, but not yet introduced :—

18 Provinces in 3 divisions

1st division.—Manila, Hoilo, Cebu, Ilocos, Cagayan.

2nd division.—Pangasinan, Pampauga, Laguna, Cavite, Batangas, Albay, N. Ecija.

3rd division.—Bulacan, Camarines, Capiz, Negros, Leyte, Marianas.

The Islands of Mindanao, Basilan, Tolo (Soolo), Samales, and Balabac, will have a special government.

ADOLF BERNHARD MEYER

Manila, April 15

* The Marianas Islands belong to the Government of the Philippines with 8,000 to 9,000 inhabitants.

MINERAL SPRING OF SHANA NEAR TREBIZOND

THE mountainous and volcanic district, or, to speak more correctly, belt, which skirts the northern coast of Asia Minor, beginning from Amastri, one hundred and fifty miles east of the Bosphorus, up to the Georgian valley and the Russo-Caucasian frontier, abounds in mineral springs, varying as to temperature and constituents, but generally endowed with hygienic properties, which are, to a certain extent, known and appreciated by the natives of the land. But few of these springs have been made the subject of scientific examination and analysis ; so that the ingredients whence they derive their value, where not discernible to the unassisted senses, are in most cases matter of conjecture rather than of demonstration.

In one instance, however, that of a remarkable mineral source within this district, the obligingness of a resident Italian chemist, M. Marengo by name, has lately furnished me with some scientific data, not indeed as complete as might have been desired, yet enough for interesting information. These I will now give, accompanied by my own observations made during frequent visits to the locality in question.

About six miles east of Trebizond on the sea-coast stands the little fishing village of Covata, at the entrance of the valley which, as also the stream that flows down it, bears the same name. Following the valley some way inland towards the mountains where it originates, we come on the water-course and ravine of Shána, falling into that of Covata at nearly right angles, from east to west. "Shána" is, like most names of places hereabouts, a word of Laz, that is Mingrelian, origin, and signifies "heat." This ravine is narrow and deep ; the rocks on either side are volcanic, chiefly mottled tufa of dark grey substance, speckled throughout with small black fragments of irregular shape and size imbedded in it. Vegetation, wherever the steepness of the slope allows it to take root, is most luxuriant ; vines, olives, walnut trees, chesnut, sycamore, maple, poplar, with a dense undergrowth of alder and hazel. Down the bottom of the gorge flows a small torrent, which joins the river of Covata not far from its sea-mouth.

Tracking the narrow path which leads up to the Shána gorge for about four hundred yards, we come on a sort of widening-out, where a horizontal sheet of porous volcanic rocks spreads to some distance alongside of, but slightly elevated above, the course of the torrent. In the middle of this rock-sheet has been formed, partly by nature, partly by art, a small circular basin, nearly three feet in diameter, and averaging a foot or rather more in depth. This is constantly full of clear, limpid-looking water, which wells up through several irregular clefts in the stone bottom of the basin, and overflows it, the waste running off down the ledge into the neighbouring torrent, and leaving everywhere on its passage a thick bright-red deposit of oxide of iron, which stains the rocks, and even discolours the main-stream to some distance. Through the clefts just mentioned bubbles of carbonic acid gas rise in sufficient abundance to give the water the appearance of boiling ; but the temperature is normal. This water is strongly impregnated with free carbonic acid ; its taste is pungent and ferruginous, with a distinct, but, so long as it is fresh, a not unpleasant indication of sulphur. If it is put into a bottle, corked, and exposed to the heat of the sun, the expansion of the gas soon causes an explosion, driving out the cork, and even bursting the bottle.

Near this semi-artificial basin, and placed on a line with it one after another in the axis of the valley, are two other natural rock-hollows, one of several feet in extent, the other less ; whence the same description of ferruginous water, mixed with bubbles of carbonic acid gas,

issues continually, but not in equal abundance, the fissures below being partially choked up, whereas those in the circular basin are carefully kept open by the peasants. Here, too, the rock around is stained with bright red streaks of iron deposit. Also, carefully observing the torrent itself, which flows in a parallel direction a few feet distant, I noticed that bubbles of gas kept rising here and there from between the stones in its bed, and that the water, though tasteless higher up, here partook to a certain extent of the mineral acidity so strongly marked in the springs.

The analysis of the ingredients of the "Shána" water, as supplied me by M. Marengo, was not quantitative, but merely qualitative. I give it as follows, apologising at the same time for any technical inexactitude in my translation from the letter of the Italian document now before me:—

INGREDIENTS

Hydrosulphuric Acid	Abundant
Carbonic Acid	Abundant
Sulphuric Acid	Not much
Chlorine	Scanty
Oxide of Iron	Very abundant
Lime	Abundant
Magnesia	Abundant
Alumina	Scanty
Soda	Scanty
Potash	Trace
Silica	Trace

Iron, free carbonic acid, sulphur, and magnesia, are the chief characteristics of this spring.

Among the Mahometan and Turkish-speaking population of the neighbourhood, the source goes by the name of "'Ilijeh," or "Healing," a term which they apply to almost every mineral spring of whatever description. As for this one in particular, the natives ascribe to it almost every sanatory virtue that a Holloway's advertisement could claim. In reality it is tonic, and, if its use be persevered in, alterative; the magnesia which it contains renders it at first slightly laxative. A considerable quantity of the water is brought in jars or bottles, which are filled and closed on the spot, to Trebizond, where it is much esteemed. The supply is unaffected by change of weather or season; only in summer the water is a few degrees cooler, as in winter warmer, than that of the torrent close by, which is often, during the severity of a Black-Sea February, changed into ice; whereas the little circular basin, in spite of its shallowness, never freezes.

The so-called "Greeks," who have a small peasant colony in the neighbourhood, have christened the source, in their modern corrupt dialect, "Iäsma," the correct word being Ἁγίασμα, or "sanctification," and have erected on an over-hanging rock close by, a small chapel, dedicated to I know not what saint, the supposed patron of the waters. The Turks, on the contrary, attach to it no religious idea whatever.

The peasants report the existence of another ferruginous spring some miles farther on among the mountains, ; but the precipitous character of the paths leading to it and the density of the forests, render it practically inaccessible to all but themselves.

Trebizond, May 28 W. GIFFORD PALGRAVE

THE DISPERSION OF SEEDS BY THE WIND

IN the very interesting notice of Grisebach's "Vegetation der Erde," which appeared in a recent number of NATURE,* reference is made to a paper by Kerner of Innsbruck, "On the Influence of the Wind on the Distribution of Seeds in Mountain Regions." As this paper was presented to the German Alpine Club, and no translation, as far as I am aware, has appeared in this country, with the exception of an abstract in the *Gardener's Chronicle*, it is probably almost unknown to English readers, and a short epitome of its most interesting features may not be unacceptable.

* Vol. v. p. 458, April 11.

The idea that the wind performs a very important part in the distribution of plants, by the extensive dispersion of their seeds, is a very prevalent one. Mr. Bentham has, however, pointed out in his Anniversary Address to the Linnean Society in 1869, that this popular belief rests on insufficient data. If that portion of thistle-down which has been carried to a considerable distance by a high wind is carefully observed, it will generally be found to have left its seed behind it; and in the same order of Compositæ, several species of *Eclipta*, *Elephantopus*, *Anthemis*, and *Lapsana*, which have no pappus, have a much more wide-spread distribution than the majority of *Senecios*, for instance, with their light and broad pappus. The rapid spread of our common thistle, *Carduus arvensis*, in any new country where it once gains a foothold, is probably as much due to the persistent vitality of its roots as to the dispersion of its seeds. If the individuals in the same field are examined, they will generally be found to be all of one sex, showing that they must have been propagated by the division of the same individual. Of the extraordinarily rapid power of dispersion possessed by some plants independently of their seeds we have a familiar instance in the suddenness with which the Canadian water-weed, *Elodea canadensis*, filled up all our canals and water-courses within a few years of its first introduction; and yet up to the present time the male plant is entirely unknown in this country, and indeed in Europe; and it is probable that the whole of the stock now in England may have sprung by sub-division from the first imported specimen.

M. Kerner conceived the idea that a careful examination of the plants growing on moraines, and of the seeds found on the surface of glaciers, would throw considerable light on this interesting subject, since it is evident that they could only have arrived in those localities by the agency of the wind; and the results of an elaborate series of investigations are recorded in the pamphlet alluded to. Firstly, with regard to the moraines:—A list of five of these floras, from as many different moraines, consisting of limestone, schist, and gneiss, included 124 species, the following orders being the most largely represented:—Compositæ, 23 per cent.; Caryophylleæ, 10 per cent.; Gramineæ, 8 per cent.; Mosses, Saxifrageæ, and Salicaceæ, 6 per cent.; Cruciferæ, 5 per cent.; Ferns and Rosaceæ, 4 per cent.; Scrophulariaceæ, 3 per cent. Of the smaller families, the genera *Valeriana*, *Epilobium*, and *Juncus*, occurred the most frequently. The investigation of these lists, with a view to trace the origin of the plants, shows that the larger number of those which constitute the moraine flora are species widely distributed over the higher mountain regions in immediate proximity to the glacier. Less frequent are those plants which belong to the grassy plateaux of the lower elevations; and still less common species belonging to the meadow or wood flora of the lowlands, which maintain only a short and precarious existence.

The absence of this latter class of plants might, however, be due to the inability of the seeds to germinate under such unfavourable circumstances; and in order to determine this point, M. Kerner carried his researches to the surface of the glacier itself, examining both the animal and vegetable productions found thereon, with the following results:—

The animals found were entirely dead or benumbed insects belonging to the orders Lepidoptera, Hymenoptera, Coleoptera, and Diptera, and consisted of forty-three species, a considerable portion of which are found only in the highest mountain regions in the immediate vicinity of the glaciers; more than half the species were of very

wide distribution, extending from the mountain valleys and neighbouring plains to the edge of the glaciers; very few being found only in the mountain valleys, and one only, the common honey-bee, being peculiar to cultivated districts. None of the insects found belong to extra-Alpine species, none of the kinds peculiar to the warm valleys of the southern Alps are represented; and the inference is unavoidable, that all the animals found on the glaciers have either strayed voluntarily, or have been driven by the wind, from districts immediately adjacent to the glacier.

The task of determining the seeds found on the surface of the glacier was much more difficult. The seeds of many Alpine plants have hardly been described; and in other instances it is difficult to distinguish between those belonging to several different species of the same genus. Thirty-six species, however, were determined with tolerable certainty, the majority of which were identical with the species previously recorded as inhabitants of the moraines. Here again the same results are established: not a single seed is found on the glacier, as not a single plant on the moraine, which does not belong to a species inhabiting the immediately adjacent mountain slopes or valleys. The conclusion from these facts seems inevitable, that the conveyance of seeds, even when provided with apparatus calculated for being floated in the air by horizontal currents, takes place only within very circumscribed limits; and that the prevalent opinion that they may be thus carried for very great distances is not supported by facts.

M. Kerner thus sums up the results of his observations:—

1. Only dust-like substances, such as pollen, spores, diatom-scales, &c., can be distributed by currents of air over wide stretches of land and sea in uninterrupted flights, and thus be brought into the alpine regions.

2. Fruits and seeds of flowering plants which are provided with a web-like floating apparatus that distends itself in dry air in the form of a parachute, are carried upwards by the ascending current of air which arises on sunny days in alpine regions on the cessation of the horizontal wind; but after sunset they sink again to the ground at a short distance in a horizontal direction; and the object attained by this floating apparatus is not so much the adaptation of the seeds for long journeys, as to enable them to settle on the projections and in the crevices of steep precipices and rocks, and to clothe with vegetation these rock-walls which are not easily accessible by other seeds.

3. The presence of membranous margins and wings favours the transport of fruits and seeds by horizontal currents of air; the horizontal distance, however, over which these seeds are carried scarcely ever extends farther than from one side of a valley to the other, and the distribution of the fruits and seeds of flowering plants, in so far as this is caused by currents of air, can only proceed gradually and step by step.

4. Fruits and seeds which are deficient in any kind of appendages that facilitate flight are scarcely influenced by currents of air; it is only when these seeds are of very minute size and extremely small weight that they can be driven short distances by horizontal winds.

It appears, therefore, that the idea that seeds are distributed to great distances by the wind, if not to be treated as a popular error, at least requires a much larger foundation of fact than it at present possesses, in order to be accepted as a scientific truth. A series of observations of this nature, if carefully conducted, is a substantial gain to Science, and may assist the determination of great physiological questions in hundreds of ways. They are within reach of every intelligent resident in the country possessed of ordinary powers of observation; and yet how few interest themselves practically in carrying them out!

A. W. B.

*LYELL'S PRINCIPLES OF GEOLOGY**

IN our last notice, after a sketch of the methods of investigation employed by Sir Charles Lyell, and an outline of the principles deduced therefrom, we gave a few examples of the kind of proofs brought forward by him to show that the degrading and transporting forces which we see in operation are producing similar phenomena to those we observe in the sedimentary rocks, and that, given sufficient time only, effects on as great a scale must be the inevitable result.

We will now select some of the evidence adduced by him to show that the igneous forces also, the movements of upheaval and depression, are as active, and the products of eruption on as grand a scale, as we have any reason to believe they have ever been within the period over which our observations extend.

The consideration of what suggested the former greater intensity in the subterranean forces, viz., the supposed vast magnitude of the ancient igneous rocks, and the proofs of variations in climate, leads Sir Charles into an investigation of the astronomical and geographical causes of vicissitudes of climate, which involves an inquiry into the vexed questions of oceanic circulation, and the effect of various changes of conditions on the organic world in the extinction of species, and their replacement by new forms of life.

It certainly may at first seem difficult to believe that the forces which produce upheaval and eruption have not varied in intensity throughout the whole period of which we have any record, and yet that over many large tracts of country, where now the faintest vibration of the distant earthquake is exceptional and rare, we have thousands of feet of volcanic ash and lava, and great masses of matter which have apparently been injected in a molten state into the fissured rock. But this difficulty has arisen because the vastness of the ancient volcanic deposits has been assumed without sufficiently detailed observation, and the magnitude of modern igneous action has been underrated, while the most important point, the transference of paroxysmal action from one area to another, has been overlooked.

Speaking of contemporaneous volcanic deposits in the older rocks, Sir Charles Lyell says:—"If one of these igneous formations is examined in detail, we find it to be the product of many successive ejections or outpourings of volcanic matter. As we enlarge therefore our knowledge of the ancient rocks formed by subterranean heat, we find ourselves compelled to regard them as the aggregate effects of innumerable eruptions, each of which may have been comparable in violence to those now experienced in volcanic regions" (p. 114). This question, however, Sir Charles does not investigate in the "Principles," which deals with the modern changes of the earth; and we will pass on to notice some of the examples he gives to show the magnitude of modern igneous action.

First, as to the fact that changes of level are going on:—"Recent observations," says Sir Charles Lyell, "have disclosed to us the wonderful fact that not only the west coast of South America, but also other large areas, some of them several thousand miles in circumference, such as Scandinavia, and certain Archipelagos in the Pacific, are slowly and insensibly rising; while other regions, such as Greenland and parts of the Pacific and Indian Oceans, in which circular or coral islands abound, are as gradually sinking" (p. 128). The atolls are themselves a proof of oscillations of level. The coral zoophytes live only within certain distances from the surface, and, having com-

* "The Principles of Geology, or the Modern Changes of the Earth and its Inhabitants considered as Illustrative of Geology." By Sir Charles Lyell, Bart. Eleventh and entirely revised edition. (London: J. Murray, 1872.) (The Second Volume has been issued since the appearance of our last notice; see NATURE v. p. 456.)

menced nearly all round an island, keep building up as the island goes down till they have formed a ring of coral. The accompanying ideal section across such an island enables one to understand the mode of growth. A channel is kept open through one side, probably at first by the stream, which drains the island, and carries down mud and fresh water, and afterwards by the scour of the tide. Whenever an area covered by such islands is upheaved, and the reefs lifted up above the breakers, or the

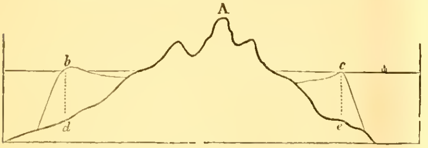

FIG. 1.—SUPPOSED SECTION OF AN ISLAND WITH AN ENCIRCLING REEF OF CORAL

A The Island; b, c highest points of the encircling reef between which and the coast is seen a space occupied by still water.

waves and wind have heaped up broken coral rock and shell around, the surface soon gets weathered, and forms a soil on which plants and animals settle and live. Sometimes the top of the island around which the coral was built is still seen; sometimes it has disappeared altogether beneath the sea. We subjoin a sketch of one of these circular reefs.

But besides such indirect evidence of gradual change of level, it is a matter of observation that as an accompaniment of volcanic action we frequently have sudden movements of small extent. For instance, in the destructive earthquake which visited Chili in 1822, the coast was raised from 2 ft. to 4 ft., while farther inland the rise was estimated at from 5 ft. to 7 ft., and off the port of Penco, if the reports of the inhabitants are to be believed, there was a rise of 24 ft. during the single earthquake of 1751. In New Zealand, during the earthquake

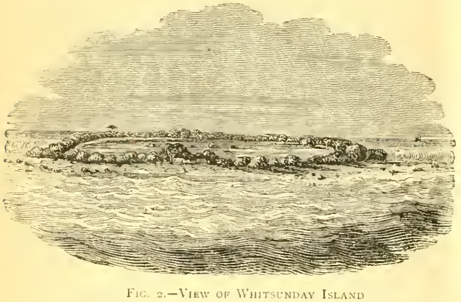

FIG. 2.—VIEW OF WHITSUNDAY ISLAND

of 1855, a fault 10 miles long, with a displacement of 9 ft., was produced.

Supposing an elevation of 7 ft. occurred only once every century, it would require less than 150,000 years to form a chain as high as the Pyrenees, and if repeated three times in a century would be sufficient to account for the Andes in the same time.

"It may be instructive," says Sir Charles, "to consider these results in connection with others already obtained from a different source, and to compare the working of two antagonistic forces—the levelling power of running water, and the expansive energy of subterranean heat. How long, it may be asked, would the Ganges require . . . . to transport to the sea a quantity of solid matter equal to that which may have been added to the land by the Chilian earthquake? The discharge of mud in one year by the Ganges at its mouth was estimated at 20,000,000,000 cubic feet. According to that estimate it would require about four centuries before the river could bear down from the continent into the sea a mass equal to that gained by the Chilian earthquake" (p. 97).

In volcanic districts especially we may expect evidence of recent upheaval and depression, and so we often have marine beds forming the base of a volcano, or submerged volcanos, whose leading features seem to be due to subaerial action. We may, for instance, mention the case of Etna, and refer our readers to the interesting line of reasoning by which our author works out the history of that mountain, showing that it was formed by degrees, of matter heaped up upon marine beds of comparatively recent age, which have now been lifted up to a considerable height above the sea, and further proves that at one time there were two principal craters from which matter was ejected, but that now, owing to subsequent explosions and denudation, an enormous valley occupies what was the top of the mountain.

As an example of a submerged volcano we may mention Santorin, with regard to which Sir Charles Lyell says:—

"We may conceive, therefore, if at some former time the whole mass of Santorin stood at a higher level by 1,200 feet, that this single ravine or narrow valley, now forming the northern entrance, was the passage by which the sea entered a circular bay. But at a still earlier period, when the ancient volcanic cone—of which the outer islands are the remains—was still more elevated above the level of the sea, there may have been a deep valley of subaerial erosion cut by the principal river which then drained Santorin, which may have consisted of one lofty volcanic cone, afterwards truncated by a paroxysmal explosion such as we have already spoken of in the case of Galongoon" (p. 72).

We subjoin Sir Charles Lyell's sketch (Fig. 3), which it will be interesting to compare with that of the unsubmerged summit of Etna.

We select also his ideal section across Barren Island (Fig. 4), to help to realise its manner of formation.

It may be worth calling attention to the similarity between the submerged crater, with its deep channel leading into it on one side, and the coral Atoll of which we have given figures above (Figs. 1 and 2). Nature has many ways of arriving at apparently analogous results; but close examination shows how varied are her methods.

Sir Charles also points out that, in the quantity of matter ejected, modern eruptions will bear comparison with any we know of in ancient times. In order to help us to realise the enormous volume of the lava poured out from Skaptar Jokul in 1783, he considers "how striking a feature" the two streams of lava then poured out "would now form in the geology of England, had they been poured out on the bottom of the sea after the deposition and before the elevation of our secondary and tertiary rocks." From one we should have a mass 100 ft. thick and 10 to 15 miles broad on the oolitic hills overlooking the vale of Gloucester. It would be traced for a distance of about 90 miles to the neighbourhood of London, where, "crowning the highest sands of Highgate and Hampstead, we might behold some remnants of the current some 500 ft. or 600 ft. in thickness, causing those hills to rival or even to surpass in height Salisbury Craigs and Arthur's Seat" (p. 52); while the other stream might be traced from London to the coasts of Devon and Dorset. The description given (pp. 104-106) of the volcanic outburst in the island of Sumbawa can hardly be read without our feeling that we know of no one ancient volcanic rock comparable in extent to the deposit of ash which must have resulted from the single eruption of 1815.

After having shown that these tremendous effects of volcanic action on the surface are "insignificant when

contrasted with the products of heat in the nether regions," Sir Charles says (p. 211):—"The continual transfer of the points of chief development of the earthquake and volcano from one part of the earth's crust to another is established as a general law by the clearest geological evidence. We have also seen that volcanic operations are now in progress on the grandest scale, and also that single currents of lava of modern date are as voluminous as any which can be shown to have ever poured out in the earliest eras to which our geological retrospect can be carried."

The doctrine of the former greater intensity of the igneous forces, connected as it generally was with the hypothesis of the primæval igneous fusion and gradual cooling down of the planet, of course involved the theory of the former higher temperature of the surface of our earth; and therefore all indications of a warmer climate over any area in the ancient seas were supposed to point

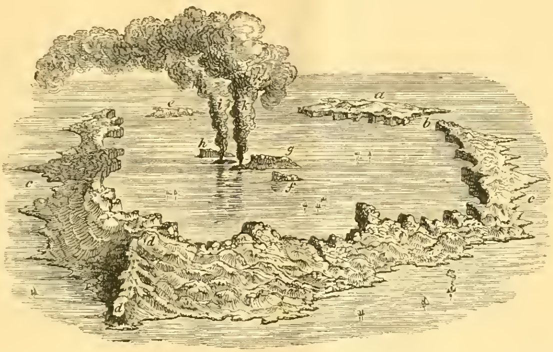

FIG. 3.—BIRD'S-EYE VIEW OF THE GULF OF SANTORIN DURING THE VOLCANIC ERUPTION OF FEBRUARY 1866

a Therasia; *b* the northern entrance, 1,068 feet deep; *c* Thera; *d* Mount St. Elias, rising 1,887 feet above the sea, composed of granular limestone and clay-slate, the only non-volcanic rock in Santorin; *e* Aspronisi; *f* Little Kaimeni; *g* New Kaimeni; *h* Old Kaimeni; *i* Aphroessa; *k* George.

to a universal higher temperature over the globe. But Sir Charles Lyell points out that "the climate of the extra-tropical regions has been by no means always hotter than now; but on the contrary, there has been at least one period when the temperature of those regions was much lower than at present" (p. 173).

Space will not allow us to follow our author while he proves, from an examination of the circumstances under which we find similar and dissimilar climates at the present day, that geographical conditions produce far greater effect upon climate than we have reason to believe would result from any astronomical combinations. Dependent to a great extent upon geographical conditions we have prevalent winds, which materially influence climate, and moreover give rise to most of the great ocean currents.

About the origin of these, however, there has been some controversy. Sir Charles considers the various theories very fully, and shows that the great currents are due to prevalent winds. "That movements," he writes, "of no inconsiderable magnitude should be impressed on a wide expanse of ocean by winds blowing for many months in one direction may easily be conceived, when we observe the effects produced in our own seas by the temporary action of the same cause. It is well known that a strong south-west or north-west wind invariably raises the tide to an unusual height along the west coast of England and in the Channel; and that a north-west wind of any continuance causes the Baltic to rise 2 ft. and upwards above its ordinary level" (vol. i. p. 492).

It is clear that when the surface water is being thus driven continuously for a long time in one direction

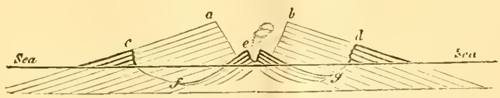

FIG. 4.—SUPPOSED SECTION OF BARREN ISLAND, IN THE BAY OF BENGAL

against a shore or into a *cul de sac*, there must be an undercurrent formed by the head of water thus produced. But in deep basins there is no reason why the water should not remain embayed for ages, and, having been at any time cold, should never receive sufficient from above or below to raise its temperature.

In the Mediterranean and the smaller seas connected with it there seems to be a great complication of current-producing causes, which have proved a fertile source of speculation and controversy ever since Aristotle puzzled over the currents of the Euripus. That land-locked sea is too small to have any considerable tide generated within itself, but the Atlantic tide rushes in and out with great force. The vast surface-current of the Atlantic, and the prevailing westerly winds, increase the in-going tide, and check, and generally altogether overpower, the surface part of the out-going tide, so as to give rise to an upper and a lower current in opposite directions through the Straits of Gibraltar.

In addition to these causes, there is the enormous evaporation during the hot season and the excess of fresh water poured in during the rainy season, which must produce a great effect. But as each tide would, when there was a deficiency of water, bring a little more in, and when an excess of water, take a little more out, this adjustment being made twice every day it does not seem likely that either evaporation or rain would make any appreciable difference in the currents at the Straits. Some authors have referred

oceanic circulation to difference of specific gravity, due to difference of temperature or amount of salinity; but, though this is a *vera causa* which might in some cases explain similar phenomena, Sir Charles shows, by reference to the observations of Captain Spratt and others, that the currents of the Mediterranean, and, indeed, all observed currents, are due to other causes.

The question of the dependence of climate, both subaerial and sub-aqueous, upon geographical conditions, is very important in its bearing upon the changes in the inorganic world. For those who believe that in the history of the crust of the earth we have evidence of alternate periods of universal catastrophic action and repose would be quite prepared to believe that in the world of life also there were alternations of destruction and creation; but to those who hold that the face of the globe has been, and is for ever being, modified by the gradual action of forces always in operation, it seems *a priori* probable that Nature should have provided the organisms which inhabit this ever-shifting earth with modifiability somewhat commensurate with the changes of the world in which they live.

A mountain has been raised and chiselled out into its present form by operations extending over a period so vast that no one can have witnessed them. A species has been changed into something quite different by processes requiring a length of time so great that no one can have watched them.

Whatever may have been the chief *causes* of the movements of upheaval, it is a *fact* that movements are going on which bring different parts of the crust within reach of denudation, and that, given sufficient time, mountain ranges must be the result.

So, whatever may be the *origin* of the variations, it is a thing definitely known that variations of the same kind as those which are considered to form specific differences do occur; it is a matter of experiment that these variations can be accumulated and perpetuated by selection; it is a matter of observation that Nature does select. The burden of proof that there are any limits to variation or natural selection rests with those who hold it.

It has been objected to the doctrine of the origin of species by natural selection that some totally distinct classes of animals have corresponding organs, so similar that it is difficult to suppose that they can "'have been brought about in two independent instances by merely indefinite and minute accidental variations.' Yet these organs in the two types must have been developed in entire and complete independence one of the other; for it would be impossible to find a common ancestor without going back to some very simple form not yet provided with even the rudiments of vision" (p. 498).

Sir Charles quotes Mr. Darwin and others to prove that in some at least of the cases adduced the similarity of structure was exaggerated. Still it is undoubtedly very great, and the study of such cases and of the mimetic forms which Mr. Wallace has so well described, makes us feel that what we chiefly want to know more about, is the law which governs the first appearance of varieties. Such facts do not so much furnish arguments against the doctrine of the origin of species by natural selection, as in favour of the existence of some law according to which external conditions and the requirements of the individuals may tend to produce variation in a given direction.

How vast and how perplexing are the questions raised by the study of the modern changes of the earth and its inhabitants; but the calm philosophic spirit which pervades the "Principles of Geology" leads us to hope that it may promote in no small degree that education which will render it "possible to welcome new truths," although they may at first appear to be "out of harmony with cherished associations of thought."

T. McK. HUGHES

NOTES

WE are informed that the Directorship of the National Observatory at Marseilles has been offered to Dr. Janssen.

25,000 rupees have already been subscribed towards the Archdeacon Pratt Memorial Fund.

WE are glad to hear that the local committee at Brighton are forming a temporary museum, to be opened during the Meeting of the British Association.

THE prizes in the Faculties of Art, Science, and Fine Arts, of University College, London, were distributed by the Right Hon. S. Cave, M.P., in the Botanical Theatre of that institution on Tuesday last. The attendance was very small, and several even of the professors absented themselves; but, notwithstanding this bad management on the part of the authorities, the proceedings were exceedingly animated and highly interesting to those engaged in the advancement of education. The report of the Dean, Prof. Croom Robertson, showed a very marked improvement in the condition of the College as well as of the School, the number of students during the past session having been greater than in any previous year. Amongst those who distinguished themselves the most notable were four ladies: Miss Orme, who was presented with the first prize and the first certificate for Political Economy, the only class in the Faculty of Arts which has as yet been opened to ladies; Miss Lupton, Miss Malden, and Miss Wylde, who received medals in the Fine Arts Faculty. The third certificate in this class was also taken by a lady; the number in the class being about thirty gentlemen and six ladies. The genuine and enthusiastic applause of the students at these successes leaves nothing to be wished for, except the continuation of that liberal policy for which University College has always been remarkable. Miss Orme had previously greatly distinguished herself at the examinations of the University of London.

THE following telegram has been received at the Admiralty from Aden, dated June 17:—"Dawson and party have returned to Zanzibar, Mr. Stanley having arrived with despatches from Livingstone: alive and well." Letters of that date from Aden are now due.

BESIDES the Minor Scholarships or Exhibitions at St. John's College, Cambridge, there will be offered for competition this year an Exhibition of 50*l.* per annum for proficiency in Natural Science, the Exhibition to be tenable for three years in case the Exhibitioner have passed within two years the previous xamination as required for candidates for honours; otherwise the Exhibition to cease at the end of two years. The Examination will commence on Friday, the 13th of December; in (1) Chemistry, including practical work in the laboratory; (2) Physics, viz., Electricity, Heat, Light; (3) Physiology; they will also have the opportunity of being examined in one or more of the following subjects: (4) Geology, (5) Anatomy, (6) Botany, provided that they give notice of the subjects in which they wish to be examined four weeks prior to the Examination. No candidate will be examined in more than three of these six subjects, whereof one at least must be chosen from the former group. It is the wish of the master and seniors that excellence in some single department should be specially regarded by the candidates. They may also, if they think fit, offer themselves for examination in any of the Classical or Mathematical subjects. Candidates must send their names to one of the tutors, Dr. Parkinson, Mr. Bonney, or Mr. Sandys, before the commencement of the Examination. The Minor Scholarships are open to all persons under twenty years of age, whether students in the University or not, who have not yet commenced residence in the University

or who are in the first term of their residence. A Minor Scholarship is tenable for two years, or until the scholar is elected to one of the Foundation Scholarships. The Exhibitions are not limited in respect to the age of candidates. It is understood that minor scholars or exhibitioners may be candidates for Sizarships.

THE announcement last week that Mr. E. R. Lankester had gained a Natural Science Scholarship at Exeter College, Oxford, should have read "Fellowship."

THE East London Museum at Bethnal Green was formally opened by the Prince and Princess of Wales on Monday last.

THE Devonshire Association for the Advancement of Literature, Science, and Art, will shortly hold its annual meeting at Exeter, under the presidency of the Bishop of the Diocese.

PROF. HUMPHRY gave his second lecture on "Human Myology" at the College of Surgeons on Wednesday, the 19th. In it he traced the elements of the lateral muscle upon the limbs, forming muscular expansions over them which, he said, were most clearly marked in the rudimentary claw-like limbs of some snakes, but sufficiently distinct in ourselves. In the upper limb, for instance, they form a superficial ventro-appendicular cone, which is divided, sectorially, into the pectoralis, the latissimus dorsi, and the trapezio-deltoid. In the lower limb the corresponding sheet is divided into the gracilis, the gluteus magnus, and the sartorius, with the tensor vaginæ femoris. The deeper layers of the ventro-appendicular cones more closely invest the shoulder and hip-joints. That in the upper limb he divided into the infra-spinatus and teres minor, the coraco-brachialis and subscapularis, and the supra-spinatus; and that in the lower limb he divided into the gluteus medius and minimus, the adductors and obturator, the iliacus and the pyriformis. The professor remarked that the developmental processes are so freely modified in accordance with the special requirements of each limb that an exact homological comparison of the muscles is out of the question; and he showed that the difference in the direction of the rotation of the upper and of the lower limbs upon their respective girdles has been attended with considerable modification of the attachment, especially of the insertion of the several muscles. He spoke of the clavicle as an ossification in one of the intermuscular septa of the ventral muscle, and as, therefore, corresponding serially with the epicostal or "intermuscular" bones developed in the abdominal wall of some lizards. Poupart's ligament belongs to the same series, and spans the crural arch as the clavicle spans the brachial arch. Various points in the disposition of the muscles of the upper parts of the limbs and the purposes served by them were discussed.

SIGNOR G. A. PASQUALE, in a paper presented to the "Accademia delle Scienze fisiche e matematiche" of Naples, attributes the injury done to vegetation by the recent eruption of Vesuvius neither to scorching nor to the mechanical action of the ashes in closing the pores of the leaves, the effect being much more sudden than if due to the latter cause; but to the injurious effects of the chloride of sodium which falls in considerable quantities with the ashes.

THE following account of the recent thunderstorm at Birmingham, by Mr. T. L. Plant, is taken from the *Gardener's Chronicle*:—"Birmingham and vicinity were visited on June 18 by a thunderstorm, accompanied by the most tremendous quantity of rain and enormous pieces of ice, ever registered within my records. The sudden heat after the low temperature in the early part of last week caused the air on the 17th and 18th to become highly surcharged with electricity. On Monday night the heat was intense, lowest thermometer 62°. The rapid increase of temperature will be understood by the following copy of my daily readings from the 12th:—

Highest Temperature in the Shade.

June 12	62°	June 17	86°
" 13	69°	" 18	88°
" 14	77°	(highest temperature recorded in June since 1858	
" 15	80°		
" 16	82°		

At 12.45 the storm commenced, and lasted three hours and a half. For fully half an hour the rolling thunder was incessant. The depositions of ice began about two o'clock, and during a period of 20 minutes to half an hour there was a fall of large frozen bodies, mingled with tremendous rain, to an extent that finds no parallel in these annals. Some of the pieces of ice (which were of most irregular formation) measured quite an inch in length. During the height of the storm the wind was high and calm in alternate succession, and changing to various points of the compass, and ultimately south, as at first. The fall of rain in this great tempest was 2·47 inches. This is the largest quantity that has been registered in Birmingham, even exceeding the great storm on the evening of July 6, 1845. Most of the rain (which is equal to 250 tons of water to the acre) fell in 45 minutes."

THE School of Science in connection with the Albert Memorial Museum at Exeter shows the zeal with which science is being cultivated in that city. The number of individual students under instruction during the current session has been 67, viz.:—7 in elementary mathematics, 13 in theoretical mechanics, 36 in inorganic chemistry, 9 in vegetable anatomy and physiology, 9 in systematic and economic botany, 7 in physical geography, 4 in machine construction and drawing, and 9 in building construction. The Museum has made considerable progress during the year.

WE have again to notice the increasing success of artizan students at the Oldham School of Science and Art, in practical Inorganic Chemistry; nineteen have passed out of twenty-one examined by the Department.

FROM the Report of the Free Libraries Committee of Birmingham for 1871, we are glad to see that, although the number of volumes in the library bearing on science is small, the demand for them shows considerable interest in these subjects among the frequenters of the library.

THE Committee of Trustees of the Industrial and Technological Museum of Victoria have issued their report for the year 1871. The progress of the Institution is spoken of as having been satisfactory, the number of visitors having greatly increased as well as of objects in the Museum. Illustrations of the mineralogical wealth of our colonies must always be of the highest importance, and there is now in the Museum a collection of the rocks of Victoria, classified and labelled, as well as a large series of fossils from different parts of the country which have not yet been classified. The models of mining machinery, formerly in the University Museum, are now also exhibited in this Museum, forming a most important and complete collection, which has excited great interest among the visitors. The exhibition of vegetable products, illustrative of their industrial uses, is rapidly increasing, and is now being systematically arranged, but is not yet catalogued. The collection of animal products, illustrative of their industrial uses, is very useful and complete. Courses of lectures have been delivered at the Museum, the primary object of which has been to make science in its relation to industry known among the artisan and mechanical classes, and the committee hope that this object has been in some measure attained.

Class lectures for practical instruction and laboratories have also been in operation.

THE circular of the University of Washington for the current year contains a catalogue of the officers and students, and a programme of the course of studies required in the different departments. In these the Physical and Natural Sciences hold a conspicuous place.

THE Deutscher Universitäts-Kalender, by Dr. F. Aschersen, published half-yearly, contains a mass of valuable information respecting all the German universities, including the names of the professors in the several faculties, the subjects for the academical prizes, &c.

WE have on our table the Reports of the Mining Surveyors and Registrars for the Colony of Victoria for the quarters ending June 30, Sept. 30, and Dec. 31, 1871.

THE Report of the Chief Commissioner of Mines for the Province of Nova Scotia for the year 1871 is printed. A report is appended of the Provincial Museum, recently established, and designed to be a permanent exhibition of the industrial resources of the province, combined with a Museum of Science and Art. The mineralogical and zoological departments appear to be well represented.

WE have received the Monthly Record for January of Results of Observations in Meteorology, Terrestrial Magnetism, &c., taken at the Melbourne Observatory, under the superintendence of Mr. R. J. Ellery.

THE American Palestine Exploration Society has, we learn from *Harper's Weekly*, lately received paper squeezes of two basaltic stones inscribed with Phœnician characters similar to, and perhaps companions of, the celebrated Moabite stone of which we have heard so much. The acquisition of the stones themselves has been a subject of much rivalry between the British and American societies; in consequence of which the Arabs, believing them to be extremely valuable, have hidden them, although it is hoped without destroying them, as was done with the Moabite stone. These squeezes were obtained by two well-known Americans, the Rev. D. Stuart Dodge and Frederick S. Winston, and have been forwarded by them to New York. Pen-and-ink copies have already been received, and have lately been lithographed and distributed among American scholars. It is not certain that the stones from which these squeezes were taken are genuine antiquities, the Orientals being unfortunately too well versed in the art of manufacturing such objects, so as to meet any demand. There is, however, a strong probability that they are what they profess to be. At any rate, they will probably before long be subjected to such an examination by experts as will determine their true character.

THE Report just issued of the Proceedings of the Geologists' Association includes detailed accounts of the visits and excursions made by the association during March and April 1871, and Messrs. R. and A. Bell's paper on "The English Crags and their Stratigraphical Divisions."

THE ninth Annual Report of the Wigan Field Naturalists' and Scientific Society contains an important paper by Mr. J. Perrins, on "The Duration of the Wigan Coalfields," illustrated by a coloured section. The Report is otherwise chiefly occupied by accounts of the different excursions of the society.

THE Bury Natural History Society has issued its first Report for the time from its foundation, in January 1868, to December 1871. Its object has been chiefly the investigation of the natural history of the district, which has been pursued with vigour; and the Report contains more or less complete lists of the flowering plants and ferns, lepidoptera, birds, mollusca, fishes, reptiles, and mammalia of the neighbourhood of Bury (the last four classes being somewhat oddly classified as the "animals" of the district).

THE "Verhandlungen der k.k. Zoologisch-botanischen Gesellchaft in Wien," for 1871, contains a number of valuable papers. Among the more important are:—Contributions to a knowledge of the Territelariæ, Thorell (or Mygalidæ), by A. Ausserer; Enumeration of the Cryptogams of Venetia, by Baron v. Hohenbühel-Heufler; Synopsis of the Fishes of the Red Sea, Part II., by Dr. C. B. Klunzinger; Monograph of the genus Certhiola, by Dr. O. Finsch; Monograph of the genus Hylæus, by Prof. Förster.

A PERIODICAL, called the *Economista di Roma*, is now published in Rome, and contains papers upon finance, agriculture, commerce, trades, public works, and statistics.

THE following reprints lie on our table, which we commend to the notice of those interested in the various subjects:—"How Fishes Breathe," by Mr. John C. Galton, from the *Popular Science Review*; "An Account of some Experiments relating to the Influence exercised by Colloids upon the Forms of Inorganic Matter," by Dr. W. B. Ord, from the "St. Thomas's Hospital Reports;" and "Non-existence of Projectile Forces in Nature," by Mr. J. A. Parker, a paper read before the American Institute.

IN a lecture on "The Influence of Human Progress on Medical Education," delivered at the Royal Victoria Hospital, Netley, Dr. W. Aitken gives an interesting sketch of the causes which have led to the improvements in the condition of medical education which have taken place especially within the last fifty years.

AN important ornithological work is announced from America as in the press, to be published by the Naturalists' Agency, Salem, Mass.—"A Key to North American Birds," by Dr. Elliott Coues, to be illustrated by seven steel plates and upwards of 250 woodcuts, and designed as a manual or text-book of the birds of North America.

WE learn from the *Garden* that Dr. Asa Gray, of Cambridge, Massachusetts, the author of "How Plants Grow," and of many important works and papers on botany, has lately brought out another little book, entitled "How Plants Behave," which deals with the climbing and other habits of plants, and is as likely to prove as valuable as the first-mentioned work.

MESSRS. W. and A. K. JOHNSTON have issued "The Edinburgh Sixpenny Quarto Atlas," a marvel of cheapness. It contains sixteen coloured maps, which, though small, are executed in the style with which we are so familiar in the productions of this house.

As an illustration of the success which generally attends well conducted zoological gardens and aquaria, we may state that, although quite recently organised, the receipts from 216,000 visitors to the aquarium at Berlin for the year 1871 amounted to nearly 40,000 dollars.

WITH reference to the alligator story which we recently printed, Mr. W. C. Easton, who found the nest containing sixty-seven eggs on Eighteen Mile Island, Fitzroy River, on the 31st January last, informs the *Rockhampton Bulletin* that he at that time placed four eggs under a hen, and on visiting the hen's nest on March 14, found two young alligators had broken their shells, and were alive and doing well. They were then of slender form, about ten inches long. Mr. Easton, who is well acquainted with the habits of the alligator, expects his young saurians will be strong enough to bring into Rockhampton for exhibition in the course of a month or six weeks.

ATOMS AND MOLECULES *

THE atomic composition of ponderable matter is a fundamental postulate in the theory of chemical equivalency. By the application of the principles of experimental research, and by methods essentially modern, resulting in the discovery of many elementary bodies and their modes of combination, a conception of very great antiquity has been rendered more distinct and worthy of credence. When this conception took definite form is not known. Indeed, it is one of the many speculations naturally elicited in discussing those subtle questions pertaining to the existence of matter and its relations to mind or spirit, the solution of which has always baffled, and will continue to baffle, the most profound thinkers. In attempting to unfold the mysteries of nature by the deductive process, the ancient teachers of Cosmogony were brought into direct conflict of opinion regarding the ultimate condition of matter. That it is composed of indestructible atoms which admit of no division, seems to have been the notion of some Oriental sages. Under the genius of the Greek philosophy this notion assumed the form and consistency of a theory.

Among those who held the doctrine, while immatured, were Ecphantus, Leucippus, and Democritus. Subsequently Epicurus introduced such modifications and improvements as were essential to its complete development.† The Latin poet Lucretius, in his "De Rerum Naturâ," has given a full exposition of the Epicurean philosophy; from this, as well as from the writings of Plutarch, it will be seen that the most prominent atomic tenets did not differ essentially from the opinions entertained by eminent scientists of modern times.‡ Newton admitted the creation of primitive particles, extremely minute, but permanent. Descartes, on the other hand, held with Aristotle, Plato, and Pythagorae that the division of matter has no assignable limit. Leibnitz attempted to reconcile the conflicting opinions of metaphysicians and mathematicians, by supposing that matter, in its ultimate condition, consists of unextended points which he denominated monads, a term borrowed from Pythagoras. At a later day, Boscovich published his celebrated dynamic theory, in which centres of force are substituted for monads. Neither of these ingenious theories however, reaches the real points of perplexity.

It is obvious that the science which treats of the ultimate composition of bodies would lead to more correct conceptions regarding minute combinations of ponderable matter. Analysis has shown that nearly all the bodies formed in the great laboratory of nature are compounds. Thus far, sixty-three different kinds of matter have resisted every effort to resolve them into simpler constituents. These substances, distinguished as chemical elements, unite in exceedingly minute quantities according to ths well-known laws of Stoichiometry. In the year 1789, Higgins, a professor in the University of Dublin, advanced the idea that certain compounds are formed by the combination of ultimate particles or atoms of different elements. Dalton, in 1803, independently arrived at a similar conclusion, which he generalised, to explain the composition of all compounds, and made it the basis of his "New System of Chemical Philosophy," published five years later. The doctrine of Dalton has undergone, since his day, such modifications as render it more acceptable; but that part of it which ascribes the union of indestructible atoms to chemical affinity may be regarded as the first successful attempt to explain that primordial action which the ancient atomists could not account for, and which the Latin poet above named describes as irregular and fortuitous.*

Chemists of the atomic school happily avoid the vexed question concerning the indivisibility of matter, by defining an atom as the smallest quantity of an element which can enter into the composition of a ponderable molecule; and the molecule, whether made up of one, two, or more elements, as the smallest quantity which can exist in a free state. However, a certain individuality must be assigned to the single atom, for a chemical decomposition requiring its transfer from one molecule to another involves its isolation *in transitu*. The absolute weight of the sixty-three different atoms cannot be ascertained; nevertheless, their relative weights have been determined with great care.

It is difficult to arrive at any clear notions concerning the size of an object so minute as to be for ever invisible under the most powerful magnifier. As an example of the conclusions regarding molecules, founded on microscopic scrutiny, that of the celebrated Ehrenberg may be cited.† Without attempting to make a close approximation towards its actual dimensions, his researches led him to infer that the diameter of an atom (the molecule of the chemist) was considerably less than six millionths of a line. Quite recently Sir W. Thomson, in a paper "On the Size of Atoms,"‡ presented four lines of argument founded on experiments of physicists, which all lead to substantially the same estimate of the dimensions of molecular structure. He says:—

"Jointly they establish, with what we cannot but regard as a very high degree of probability, the conclusion that, in any ordinary liquid, transparent solid, or seemingly opaque solid, the mean distance between the centres of contiguous molecules is less than the hundred-millionth and greater than the two thousand-millionth of a centimetre. To form some conception of the degree of cross-grainedness indicated by this conclusion, imagine a rain-drop, or a globe of glass as large as a pea, to be magnified up to the size of the earth, each constituent molecule being magnified in the same proportion. The magnified structure would be coarser grained than a heap of small shot, but probably less coarse grained than a heap of cricket balls."

From these deductions of Thomson some idea may be formed of minute molecular grouping; and I venture the suggestion that, in regard to size, the smallest bullet would probably stand about mid-way between the *glomeramen minimum* and "the great globe itself."

Beyond this point of extreme tenuity, where matter first exhibits that property which is revealed in visible forms, we are forced to consider it in a still more expanded state, as the universally diffused medium of light, heat, and actinism; consequently this conception of the minute ponderable globule does not bring us very near the *minima naturæ*, for a difference in size cannot be less marked between ponderable atoms and those infinitesimal particles forming the luminiferous ether or æth which fills the interstellar spaces, and which, in a more condensed state, probably forms the interatomic medium. Assuming that all forces generating wave motions in elastic fluids follow the same law of propagation, I endeavoured some years ago to estimate the density of this inconceivably attenuated substance.§

In that calculation the density of air is the unit of measure. If instead hydrogen be taken as the unit, the density of luminiferous ether is expressed by the decimal ·00000000001653. Whatever may be its actual density, its reality must be admitted, until the positions established by the investigations of Huyghens,

‡ A full exposition of the ancient atomic philosophy would be foreign to the purpose of this paper. Many of the prevailing erroneous impressions concerning it would, however, be corrected by an examination of the third chapter of Dr. Good's "Book of Nature," in which Epicurus is ably defended against the charge of atheism. Evidently the Epicureans were opposed to Mythology; but while ignoring the power of its gods, they were naturally led to the recognition of a higher Power, an Intelligent Cause, Self-existent, and Supreme. This deduction was reached by the earnest believers in the atomic doctrine. According to Stobæus, Ecphantus supposed the material world to consist of atoms, but yet to be ordered and governed by a Divine providence. Ἔκφαντο, ἐκ μεν τῶν ἀτόμων συνεστάναι τὸν κοσμὸν, διοικεῖσθαι δὲ ἀπο προνοίας. Eclog. Physic. lib. 1. cap. xxv. And as evidence of the belief prevalent among wise men several centuries later, Berzelius, in his paper on "Proportions determinate," quotes from Philo, who, in his collection of the choice philosophical ideas of his time ("Libri Sapientiæ," cap. xi. v. 22), says:—Παντα Θεὸς μέτρῳ καὶ ἀριθμῷ καὶ σταθμῷ διέταξε ("God made all things by measure, number, and weight"). This remarkable statement, as far as it relates to things terrestrial, modern chemical investigations have fully confirmed.

* Omnimodis coire, atque omnia pertentare,
Quæcunque inter se possint congressa creare.

§ Sound would be propagated, with exactly the velocity of light through a fluid, under the standard pressure, 874,094,104.900 times rarer than air. Therefore, if the density of air be 1, the density of æth is represented by the decimal ·000,000,000,001,144+.

It will not be inferred from this view that the aim has been to reach

"The first of things, quintessence pure,"

for the elastic quality of æth involves the hypothesis of a still more subtle fluid. We have raised one curtain only to find another to be raised. As the unfathomed vaults of Heaven recede before the sweep of a more powerful refractor, and nebulæ resolved reveal nebulæ beyond, so the most diminutive germ that springs from the Creator's touch discloses through the lens of higher power new signs of more wonderful mechanism within. Each nucleus has its nuclei! Each entoblast is but the boundary of a microcosm! Each particle a galaxy of atoms revolving in the all-pervading æth! Thus, before every far-reaching human advance, *Circumference* and *Centre* will for ever retreat.—*Transactions of the American Institute*, 1864, p. 539. ("Clydonics," No. 1)

Young, Fresnel, Foucault, and Fizeau, are shown to be untenable. A very able American metaphysician, in meeting an objection brought by Huxley against the views of Comte, has strongly expressed his unqualified dissent;* nevertheless, the hypothesis that light, heat, and actinism are propagated by the undulations of a subtle all-pervading fluid, is the only one which satisfactorily accounts for a certain class of phenomena, and it is accepted by all the prominent experimental physicists of the present day.

The vast difference in density indicated cannot be apprehended, because numerical comparisons utterly fail to raise in the mind any clear conception regarding a fluid so attenuated; yet it naturally suggests the idea that there must be many intervening conditions of matter in which it exists in successive degrees of increasing density, and that these conditions form the connecting links, so to speak, between its apparently imponderable and its ponderable states. Something like this opinion seems to have been maintained in a curious work published in England many years ago.† The reverend author, viewing the universe as a systematic manifestation of the Divine Will, assumes that the medium of light is the mother element from which by progressive steps the chemical elements have been evolved. Proceeding from the first lines of morphology he arrives at the primitive form which cannot be isolated; then by an exceedingly ingenious synthetic process he represents by diagrams his ideal structure of different kinds of atoms, all of which are duplications of the tetrahedron. Thus he claims to reveal the unit, by multiples of which the atomic weight of all chemical elements may be expressed, and so arrives at a result which will be recognised as simply a modification of the so-called law of Prout. Although this, and other remarkable surmises by Macvicar are, for reasons which need not here be adduced, quite untenable, he seems to have led the way to an assumption which has recently met with some favour, namely, that the chemical atom, although indivisible, is a collection of smaller particles. However, in following this author towards the infinitesimal, we only realise more fully the truth that above and below the narrow zone of the visible are objects too far off and too fine for human scrutiny. Although the *seeming all* is rounded by intimation of other and brighter regions, Science can never compass them by any extension of her domain! In those unsounded depths which form the boundary and background of the known, thought grown dizzy finds no support; and even the positivist turns back bewildered when mensuration fails and computations end in surds!

On examining the numerous works on chemistry published within the last twenty years, one cannot fail to notice a gradual change in the expressions employed in describing reactions. The word "equivalent" seems to have lost the meaning originally assigned to it by Wollaston, and the terms "combining weight" and "combining proportion" are now used less frequently than "atomic weight" and "atom." This abandonment of old forms of expression doubtless indicates a gradual change of opinion among leading chemists, a change which may be ascribed partly to an accumulation of facts tending to confirm the atomic theory, and, partly, to the promptings of that mysterious intuition which, overleaping the limits of logic, often arrives at correct conclusions even before their truth has been demonstrated.

During all the discussions on "atomicity" hardly a doubt has been raised as to the actual existence of the atom. It was not, therefore, surprising that the chemical world received a sensible shock at the stand made by Brodie in 1868.‡ However, a careful examination of his paper is likely to lead to the conclusion that the objections to the atomic theory therein enumerated are not more formidable than those which can be urged against his own ingenious, but complicated method of chemical operations. Precision in signs and definitions leads to exact results in the abstract, nevertheless a mathematical formula often requires modification to meet the varying conditions found in actual practice, and even then it only gives a near approximation to the truth.

Renewed attention to this subject was doubtless the means of drawing from the then President of the London Chemical Society a paper "on the Atomic Theory," which is generally regarded as the best exposition and defence of the doctrine yet made, and which may be consulted with profit by those desiring to obtain a clear statement of the principal results of chemical research adduced for its confirmation.*

A vigorous attack on the atomic theory has since been made by Mills, the real tendency of which is to raise doubts concerning the existence of matter itself.† He quotes with evident satisfaction from a work by Digby "on the nature of bodies" printed in 1645, wherein *quantity* is defined "as but one whole that may indeed be cut into so many several parts; but those parts are really not there till by division they are parcelled out; and then the whole (out of which they are made) ceaseth to be any longer, and the parts succeed in lieu of it, and are every one of them a new whole." From this statement proceeds a train of geometrical reasoning concerning extension and division which leads to the old dilemma regarding finite and infinite indivisibles.

Fortunately a new science, unknown to Digby, has demonstrated that matter has other than mere physical properties which are so clear and well defined as to enable its votaries to determine the ultimate composition of all bodies. The chemist affirms that, however inclined we may be to regard a body as a whole, it is in fact composed of minute parts which may be separated, and that in the great majority of bodies, which are compounds, Nature has herself made divisions by incorporating unlike parts which may be replaced by other unlike parts. On questions relating to the actual size of these parts, their form, their structure, &c., he makes no issue; he simply asserts that all these ultimate parts are permanent, and that those composed of the same kind of matter are identical in size and structure. The limits proposed for this paper will permit elucidation of this point alone.

The clearest conception of molecules and atoms will be arrived at by examining the principal phenomena attending the mechanical mixture and final chemical union of the lightest and the heaviest of the simple gases. The electro-positive element, hydrogen, is a permanently elastic gas, having a relative density expressed by 1. Its properties are in marked contrast with those of chlorine, a yellowish green gas, which may be condensed into a liquid, by a pressure of about four atmospheres. The density of this strong electro-negative element is 35·5. If two vessels of equal capacity, filled with these gases respectively, be placed in the dark, one over the other, and a communication be opened between them, a mutual diffusion of the gases will commence, the relative velocity being inversely as the square root of their densities. The action continues untraversed by the force of gravitation until minute portions of hydrogen and chlorine are equally diffused throughout both receptacles. This phenomenon cannot be accounted for, excepting on the supposition that minute parts of each gas have undergone complete isolation. If diffusion were effected only through a single stratum or extremely thin layer, it would be possible for two gaseous elements to retain their continuity by passing each other in intertwining streams, thus forming like threads, a warp and woof; but when diffusion is in every direction it is obvious that these elements must positively separate each other, and thus be divided into extremely diminutive bodies each of the same dimensions. Let l represent the lighter gas, d the denser, and e the dimensions or size of each isolated portion, then el and ed will denote the dissimilar parts of which the whole gaseous matter is composed. As the phenomenon of diffusion occurs under the conditions mentioned, whatever may be the quantity of gases employed, it follows that el and ed are individual volumes or molecules, invariably of the same dimensions. This diffusion of gases may therefore be defined as the uniform intermingling of dissimilar molecules.

If the molecules el and ed thus commingled while in the dark be exposed to direct sunlight, an instantaneous and complete chemical combination occurs with explosive violence but without condensation; or if exposed to diffused daylight, the union of elements will be gradual and without explosion; the resulting compound in each case being hydrochloric acid gas.

The affinity or force of chemism is generated by the action of light on the coloured gas chlorine, which, by absorbing all the rays and transmitting only the yellowish green, acquires a power which seems to be expended by the union of that element with hydrogen. Early in the present century M. Benard announced that the new properties acquired by chlorine on exposure to light were derived from the violet ray. In 1843 Draper proved by experiment the relative power of each ray in producing this

change, the actinic rays being altogether the most effective.* Mr. E. Budde has recently described a remarkable experiment in this direction. He found that a differential thermometer filled with chlorine expanded about seven times more in the violet than in the red ray of the solar spectrum; when the same thermometer was filled with CO_2 no action was noticed.†

As the combination of hydrogen and chlorine is effected without change of volume, it is obvious that the molecule *cl* does not unite with the molecule *cl*, forming a compound molecule *cl-cl*. The conclusion is therefore unavoidable that each molecule has been divided into two equal parts, and that by affinity, like parts have been separated, and unlike parts have been united. These parts are the smallest quantities that can be isolated, and are in fact the atoms recognised by the chemist. If this smallest combining proportion or atom be designated by *a*, the actual composition of the hydrogen molecule *cl*, weighing 2, may be clearly represented by *al-al* (weight 1 + 1), and the chlorine molecule *cl* weighing 72, by *al al* (weight 35·5 + 35·5). As the attraction of *al* to *al*, and of *al* to *al* is, after exposure to light, less than of *al* to *al*, there is an instantaneous chemical change by which one molecule of hydrogen and one molecule of chlorine are transformed into two molecules of hydrochloric acid gas. This reaction is clearly indicated by the following equation: *al-al* + *al-al* = *alal* + *alal* = 2 *alal*.

The symbols here used are intended to convey to the mind an idea of the relative size of combining parts, which is not so apparent when expressed as follows:—

$$H_2 + Cl_2 = HCl + HCl = 2\,HCl.$$

From the simplest of molecular types we might proceed to the most complex; and, throughout, if we consider the combining proportion of each simple constituent as either a unit or a multiple of a unit, the composition of each molecule may be expressed by whole numbers. Thus having as many different kinds of units as there are elements, any true chemical combination may be symbolised by a combination of arithmetical ratios. This method, under the light of the atomic theory, clearly reveals the harmonic relations of molecular constituents, which, seen from the stand-point of percentage composition, appear unconnected and discordant.

It must be admitted that many of the reactions of well-known bodies have not yet been determined quantitatively; yet were they made out, we should not be able to demonstrate by experiment the truth of the atomic doctrine. It still remains a theory, in favour of which there are many facts and phenomena that collectively form an argument not easily to be outweighed. This evidence may be briefly summarised as follows:—

1. *Atomic Weights.* Elements combine in extremely minute parts, according to the law of definite and multiple proportions. The atomic weight of an element is either its equivalent weight or a multiple of it, as such multiple cannot be divided by reactions, its weight must conform with the atomic number. Whatever changes of position the combining weight of an element may undergo in a series of molecular metamorphoses, that is to say, however many times it may be displaced and replaced in chemical combinations, it invariably retains its characteristic weight. This invariability of weight is an essential property of the atom.

2. *Atomic Volume.* Gases unite in equal volumes or multiple volumes. If hydrogen be taken as unity, the density of each elementary gas is identical with the weight of its atom. The atomic volume, determined by dividing the atomic weight of a body by its specific gravity, has been the means of revealing many interesting relations among compounds of similar structure, and among many containing different components and of unlike structure.

3. *Atomic Heat.* It has been shown by experiment that quantities of each element conforming with its atomic number have the same capacity for heat, excepting only carbon, boron, and silicon; these, it is believed, will yet be found to conform to the law, that the specific heats of atoms are the same. This law is regarded as a direct confirmation of atomic weights.

4. *Molecules.* According to the atomic theory chemical forces are brought in equilibrium when atoms combine and form a molecule. Every gas and every vapour undecomposed has a density proportional to its molecular weight. All known molecular combinations and combining proportions are in accordance with the atomic doctrine. Decomposition by electrolysis affords some evidence that the constituent parts of a molecule which are simultaneously separated are proportionate to atomic weights.

5. *Atomic combining capacity.* The modern doctrine of types and substitutions is solely based on the individuality of the atom, without which the whole fabric of typical structures must fall.

6. *Isomerism.* The fact that bodies containing the same elements, and in precisely the same proportions, exhibit different properties, has been thus far accounted for, only on the supposition that atoms are differently arranged in each body. These differences in arrangement depend not only on the relative position of atoms, but also on the order as to time in which they combine; for two or more atoms having such precedence over others as to combine first, may, by that means, form a radical of such permanence as to play the part of an atom. Apart from the question of radicals, we may ascertain the number of different bodies which can be formed from the same number of different atoms, by an application of the mathematical law of permutations.

7. *Homogeneity.* The uniformity of structure and appearance of any element or chemical combination of elements furnishes the most palpable proof of the identity in size and shape of those definite parts which we designate as molecules. This homogeneity is retained under different degrees of pressure, thus making it apparent that molecules are not identical in structure, but that they approach and recede in precisely the same manner under the same conditions.

Finally.—The foregoing statement regarding the existence of atoms which are indivisible and indestructible under the present order of things does not preclude the supposition that the atom may be a cluster of smaller particles held together by a powerful affinity, which, when counteracted, would leave them free to move within a given sphere. On this assumption it is highly probable that the relative position of such particles may modify the combining capacity of the atom. Moreover, the normal motion of such particles may determine not only the peculiarities of elemental spectra, but produce other effects not dependent on the amplitude of atomic oscillations, thus favouring the inference that the atom itself is a receptacle of force.

† *Pogg. Annalen* for 1871, No. 10.

BLOOD-RELATIONSHIP*

I PROPOSE in this memoir to deduce by fair reasoning from acknowledged facts a more definite notion than now exists of the meaning of the word "kinship." It is my aim to analyse and describe the complicated connection that binds an individual, hereditarily, to his parents and to his brothers and sisters, and, therefore, by an extension of similar links, to his more distant kinsfolk. I hope by these means to set forth the doctrines of heredity in a more orderly and explicit manner than is otherwise practicable.

From the well-known circumstance that an individual may transmit to his descendants ancestral qualities which he does not himself possess, we are assured that they could not have been altogether destroyed in him, but must have maintained their existence in a latent form. Therefore each individual may properly be conceived as consisting of two parts, one of which is latent and only known to us by its effects on his posterity, while the other is patent and constitutes the person manifest to our senses.

The adjacent, and, in a broad sense, separate lines of growth in which the patent and latent elements are situated, diverge from a common group and converge to a common contribution, because they were both evolved out of elements contained in a structureless ovum, and they jointly contribute the elements which form the structureless ova of their offspring.

The annexed diagram illustrates my meaning, and serves to show clearly that the span of each of the links in the general chain of heredity extends from one structureless stage to another, and not from person to person.

$$\begin{array}{r} \text{Structureless} \\ \text{elements in} \\ \text{Father} \end{array} \left\{ \begin{array}{l} \text{......Adult Father ......} \\ \\ \text{......Latent in Father......} \end{array} \right\} \begin{array}{l} \text{Structureless} \\ \text{elements in} \\ \text{offspring.} \end{array}$$

I will now proceed to consider the quality of the several relationships by which the above terms are connected together.

The observed facts of Reversion enable us to prove that the latent elements must be greatly more varied than those that are personal or patent. The arguments are as follows:—(1) There

* Read before the Royal Society, June 13, by Francis Galton, F.R.S.

must be room for very great variety, because a single strain of impure blood will reassert itself after more than eight generations; (2) an individual has 256 progenitors in the eighth degree, if there have been no ancestral intermarriages, while under the ordinary conditions of social and neighbourly life, he will certainly have had a considerable, though a smaller, number of them; (3) the gradual waning of the tendency to reversion as the generations increase, conforms to what would occur if each fresh marriage contributed a competing element for the same place, thus diluting the impure strain until its relative importance was reduced to an insignificant amount. It follows from these arguments that for each place among the personal elements there may exist, and probably often does exist, a great variety of latent elements that formerly competed to fill it.

I have spoken of the primary elements as they exist in the newly-impregnated ovum, where they are structureless, but contain the materials out of which structure is evolved. The embryonic elements are segregated from among them. On what principle are they segregated? Clearly it is on some principle whose effects are those of "Class Representation," using that phrase in a perfectly general sense, as indicating a mere fact, and avoiding any hypothesis or affirmation on points of detail, about most, if not all, of which we are profoundly ignorant. I give as broad a meaning to the expression as a politician would give to the kindred one, a "representative assembly." By this he means to say that the assembly consists of representatives from various constituencies, which is a distinct piece of information so far as it goes, and is a useful one, although it deals with no matter of detail; it says nothing about the number of electors, their qualifications, or the motives by which they are influenced; it gives no information as to the number of seats; it does not tell us how many candidates there are usually for each seat, nor whether the same person is eligible for, or may represent at the same time, more than one place, nor whether the result of the elections at one place may or may not influence those at another (on the principle of correlation). After these explanations there can, I trust, be no difficulty in accepting my definition of the general character of the relation between the embryonic and the structureless elements, that the former are the result of election from the latter on some method of Class Representation.

The embryonic elements are *developed* into the adult person. "Development" is a word whose meaning is quite as distinct in respect to form, and as vague in respect to detail, as the phrase we have just been considering; it embraces the combined effects of growth and multiplication, as well as those of modification in quality and proportion, under both internal and external influences. If we were able to obtain an approximate knowledge of the original elements, statistical experiences would no doubt enable us to predict the average value of the form into which they would become developed, just as a knowledge of the seeds that were sown would enable us to predict in a general way the appearance of the garden when the plants had grown up. But the individual variation in each case would be great, owing to the large number of variable influences concerned in the process of development.

The latent elements in the embryonic stage must be developed by a parallel, I do not say by an identical process, into those of the adult stage. Therefore, to avoid all chance of being misapprehended when I collate them, I will call, in the diagram I am about to give, the one process "Development (*a*)" and the other "Development (*b*)."

It is not intended to affirm, in making these subdivisions, that the embryonic and adult stages are distinctly separated; they are continuous, and it is impossible but that they should overlap, some elements remaining embryonic while others are completely formed. Nevertheless the embryo, speaking broadly, may fairly be looked upon as consecutive.

Again, the two processes are not wholly distinct; on the contrary, the embryo, and even the adult in some degree, must receive supplementary contributions derived from their contemporary latent elements, because ancestral qualities indicated in early life frequently disappear and yield place to others. The reverse process is doubtful; it may exist in the embryonic stage, but it certainly does not exist in a sensible degree in the adult stage, else the later children of a union would resemble their parents more nearly than the earlier ones.

Lastly, I must guard myself against the objection, that though structure is largely correlated, I have treated it too much as consisting of separate elements. To this I answer, first, that in describing how the embryonic were derived from the structureless elements, I expressly left room for a small degree of correlation; secondly, that in the development of the adult elements of the embryonic, there is a perfectly open field for natural selection, which is the agency by which correlation is mainly established; and thirdly, that correlation affects groups of elements, and not the complete person, as is proved by the frequent occurrence of small groups of persistent peculiarities, which do not affect the rest of the organism, so far as we know, in any way whatever.

The ground we have already gained may be described as follows:—

Out of the structureless ovum the embryonic elements are taken by Class Representation, and these are developed (*a*) into the visible adult individual. On the other hand, returning to our starting-point at the structureless ovum, we find, after the embryonic elements have been segregated, the large residue is developed (*b*) into the latent elements contained in the adult individual. All this is summarily expressed in the first two columns of the diagrams below. I might have inserted vertical arrows to show the minor connections between the corresponding stages in the two parallel processes, but it would have complicated the figure.

In what way do the patent and latent adult elements respectively contribute representatives towards the structureless stage of the next generation? We know that every quality they possess may be transmitted to it, but it does not follow that they are invariably transmitted. The contributions from the patent elements cannot be by "Class," because their own original elements have been themselves specialised, and therefore can contain no more than one or a few members of each class (which, it is true, must have been somewhat developed, both in numbers and variety). Their contributions may therefore be justly described as being effected on some principle that has resulted in a "Family representation," though whether in a strictly universal representation I do not profess to say.

As regards the large variety of adult latent elements, they cannot all be transmitted, for the following obvious reason; the corresponding qualities of no two parents can be considered exactly alike; therefore the accumulation of sub-varieties, if they were all preserved, as the generations rolled onwards, would exceed in multitude the wildest flights of rational theory. The heritage of peculiarities through the contributions of 1,000 consecutive generations, even supposing a great deal of ancestral intermarriage, must far exceed what could be packed into a single ovum. The contributions from the latent adult elements are therefore no more than representative; but we know they cannot be so on the broad principle of "class representation," if the word "class" be applied to the same large orders as before, and if the representatives are few in number, because it is incumbent on them to furnish all the various members of each Class whence the representatives have to be drawn. Therefore, bearing in mind what has been just argued, that it is impossible for the elements of every individual quality to be contributed, we are driven to suppose, as in the previous case, a "Family Representation," the similar elements contributed by the two parents ranking, of course, as of the same family. It is most important to bear in mind that this phrase states a fact and not an hypothesis; it does not mean that each and every Family has just one representative, for it is absolutely reticent on all matters of detail, such as those I enumerated, when speaking of Class Representation. To show the importance which I attach to this disclaimer, I may be permitted to mention what appears to me the most probable *modus operandi*, namely, that it is in reality a large selection made on a broader and not a narrower system than that of classes, and similar to that obtained by an indiscriminate conscription; thus, if a large army be drawn from the provinces of a country by a general conscription, its constitution, according to the laws of chance, will reflect with surprising precision the qualities of the population whence it was taken; each village will be found to furnish a contingent, and the composition of the army will be sensibly the same as if it had been due to a system of immediate representation from the several villages.

The following diagram expresses the whole of the foregoing results:—It begins with the structureless elements, whence the parent individual was formed, and ends with its contributions to the structureless elements, whence his offspring is formed.

I will now inquire, what are, roughly speaking, the relative proportions of the contributions to the elements of the offspring made respectively by the patent and latent elements of the adult parent? It is better not to complicate the inquiry by speaking, at first, of these elements in their entirety, but rather of some

special characteristic; thus, to fix the ideas, suppose we are speaking about a peculiar skin-mark in an animal. The peculiarity in question may be conceived (1) as purely personal, without the concurrence of any latent equivalents, (2) as personal but conjoined with latent equivalents, and (3) as existent wholly in a latent form. It can be shown that, in the first case, the power of hereditary transmission is exceedingly feeble, for notwithstanding some exceptions (as in the lost power of flight in domestic birds), the effects of the use and disuse of limbs, and those of habit, are transmitted to posterity in only a very slight degree. Again, it can be fairly argued that many classes of cases which seem at first sight to fall under case (1), that is, to be purely personal, and to prove a larger hereditary influence than what I assign to it, do really belong to case (2). Thus, when individuals born with a peculiar mark are reputed to be the first of their race in whom it had ever appeared, it would be hazardous in the extreme to argue that the latent elements of that mark were wholly deficient in them. It is very remarkable (I was indebted for a knowledge of this fact to Mr. Tegetmeier) how nearly every bar or spot found in any species of an animal in its wild state may be bred into existence in the domesticated variety of that species; showing that the elements of all these bars and spots are universally present in all varieties of the species, though their manifestation may be overborne and suppressed. We therefore see that the hereditary influences of an animal with respect to any particular spot are, I will not say in every case, but certainly on the average of many cases, much more numerous than if that spot had been purely a personal characteristic, without the concurrence of any latent elements. Bearing this argument in mind, we shall more justly estimate the import of the statistical evidence to be obtained from breeders of animals. I should judge from the impression left by many scattered statistics that it is perfectly safe to affirm that breeders, when they mate two animals, each having the same unusual characteristic, not through known hereditary transmission, but by supposed variation, would consider themselves fortunate if one quarter of the progeny inherited that quality. Now these successful cases are, as I have shown, on the average, the produce of parents having the peculiarity not only in a personal, but also, to some degree, in a latent form. We may therefore reasonably conclude that, had the latter portion been non-existent, the ratio of successful cases would have been materially diminished.

I should demur on precisely the same grounds to objections based on the fact of the transmission of qualities to grandchildren being more frequent through children who possess those qualities than through children who do not; for I maintain that the personal manifestation is on the average, though it need not be so in every case, a certain proof of the existence of some latent elements.

Having proved how small is the power of hereditary transmission of the personal elements, we can easily show how large is the transmission of the purely latent elements, in the case (3) by appealing to the well-known facts of reversion; but into these it is hardly necessary for me to enter at length. The general and safe conclusion is that the contribution from the patent elements is very much less than from the latent ones.

If we now combine our results into a single diagram, showing the fainter stream of heredity by *italic lines*, and indicating those processes by asterisks (*) which were described at length in the previous figure, we shall easily recognise the complexity of hereditary problems. We see that parents are very indirectly

Structureless elements of parent . .	through "Class-Representation" afford	Embryonic elements . . .	which by "Development" (*a*) become	Adult elements	which by "Family Representation" contribute to .	Structureless elements of offspring.
	"Residue" after the abstracted elements are	Latent elements in embryo	which by "Development" (*b*) become	Latent elements in adult . .	which by "Family Representation" contribute to .	

Structureless elements of father	* *Embryonic*	* *Adult FATHER* *	Structureless elements of offspring . . .	* Embryonic	* Adult OFFSPRING.
	* Latent in embryo	* Latent in adult father *		. . .	. . .
Structureless elements of mother	* *Embryonic*	* *Adult MOTHER* *			
	* Latent in embryo	* Latent in adult mother *			

and only partially related to their own children, and that there are two lines of connection between them, the one of large and the other of small relative importance. The former is a collateral kinship and very distant, the parent being descended through two stages (two asterisks) from a structureless source, and the child (so far as that parent is concerned) through five totally distinct stages from the same source. The other, but unimportant line of connection, is direct, and connects the child with the parent through two stages. We shall therefore wonder that, notwithstanding the fact of an average resemblance between parent and child, the amount of individual variation should not be much greater than it is, until we have realised how complete must be the harmony between every variety and its environments, in order that the variety should be permanent.

We also infer from the diagram how near, and yet how subject to variation, is the kinship between the children of the same parents; for only two stages are required to trace back their descent to a common origin, which, however, proceeds from four separate streams of heredity, namely, the adult patent and latent elements of each of the two parents.

An approximate notion of the nearest conceivable relationship between a parent and his child may be gained by supposing an urn containing a great number of balls, marked in various ways, and a handful to be drawn out of them at random as a sample. This sample would represent the person of a parent. Let us now suppose the sample to be examined, and a few handsful of new balls to be marked according to the patterns of those found in the sample, and to be thrown along with them back into the urn. Now let the contents of another urn, representing the influences of the other parent, to be mixed with those of the first. Lastly, suppose a second sample to be drawn out of the combined contents of the two urns, to represent the offspring. There can be no nearer connection justly conceived to subsist between the parent and child than between the two samples; on the contrary, my diagram shows the relationship to be in reality much more remote, and consisting of many consecutive stages, and therefore hardly to be expressed by such simple chances. Whenever the balls in the urns are much of the same pattern, the samples will be alike, but not otherwise. The offspring of a mongrel stock necessarily deviate in appearance from each other and from their parents.

We cannot now fail to be impressed with the fallacy of reckoning inheritance in the usual way, from parents to offspring, using those words in their popular sense of visible personalities. The span of the true hereditary link connects, as I have already insisted upon, not the parent with the offspring, but the primary elements of the two, such as they existed in the newly impregnated ova whence they were respectively developed. No valid excuse can be offered for not attending to this fact, on the ground of our ignorance of the variety and proportionate values of the primary elements. We do not mend matters in the least, but we gratuitously add confusion to our ignorance, by dealing with hereditary facts on the plan of ordinary pedigrees—namely, from the persons of the parents to those of their offspring.

It will be observed that, owing to the clearer idea we have now obtained of the meaning of kinship and of the consecutive phases of the chain of life, the various causes of individual variation can be easily and surely sorted into their proper places. I will mention a few of them, merely as examples.

In the segregation of the embryonic elements, if the structure-

less ones be diverse without any strongly preponderating element, it is impossible to foresee the character of the embryo, just as it is impossible to foresee the character of a handful chosen from an urn containing a mixed assemblage of variously coloured balls. But if they be not diverse, then the embryonic elements will be a true sample of the structureless ones, the conditions of purity of blood are fulfilled, and the offspring will resemble its parents.

We also see, in the process by which the embryonic elements are obtained, how the curious phenomenon may occur of inheritance occasionally skipping alternate generations. The more that has been removed from the structureless group for the supply of the embryonic (which as we have seen, in a nearly sterile destination) the less remains for the latent group, too little, it may be, to assert itself by that, the only prolific, line of transmission In the supposed case it would recuperate itself during the succeeding generation, where the elements in question will have remained wholly latent, owing to their insignificance in the structureless stage of that generation, which would be sufficient to secure any portion of it from selection for the embryonic form.

It is in the stage of development where I presume those influences to come in, which cause domesticated animals, when turned loose, to become feral. No variety can be stable unless the conditions of development concur to maintain the structureless stages of consecutive generations in an unchanged form. It is clearly of no avail to a breeder to obtain a stock by continued and careful selection, that shall conform to a desired type, if the animals be afterwards reared under other conditions, by which the subsequent stages, both latent and patent, shall be modified.

Lastly, it is in the process of selection of elements, both latent and patent, from the adult parents for the structureless stage of the next generation, where I suppose the curious and unknown conditions usually to occur, through which a change in the habits of life, after the adult age has been reached, is apt to produce sterility. I may be permitted to remark, hypothetically, that this view appears to be corroborated by the fact, that many grains of pollen or many spermatozoa are required to fertilise each ovum, because, as it would seem, each separate one does not contain a sufficiently complete representation of the primary elements to supply the needs of an individual life, and that it is only by the accumulation of several separate consignments (so to speak) of the representative elements, that the necessary variety is ensured. I argue from this that there is a tendency to a large individual variation in the constituents of each grain of pollen, or spermatozoön, and, by analogy, that there is a similar though smaller tendency in each ovum. Also, that changes in the habits of life may increase this variation to a degree that involves sterility.

One result of this investigation is to show very clearly that large variation in individuals from their parents is not incompatible with the strict doctrine of heredity, but is a consequence of it wherever the breed is impure. I am desirous of applying these considerations to the intellectual and moral gifts of the human race, which is more mongrelised than that of any other domesticated animal. It has been thought by some that the fact of children frequently showing marked individual variation in ability from that of their parents, is a proof that intellectual and moral gifts are not strictly transmitted by inheritance. My arguments lead to exactly the opposite result. I show that their great individual variation is a necessity under present conditions, and I maintain that results derived from large averages are all that can be required, and all we could expect to obtain, to prove that intellectual and moral gifts are as strictly matters of inheritance as any purely physical qualities.

SOCIETIES AND ACADEMIES

London

Chemical Society, June 20.—Dr. Frankland, F.R.S., president, in the chair. The president announced that Mr. Hyde Hills had given ten guineas to the fund for promoting original research, and promised to further increase the donation by ten guineas for each ninety subscribed for the same purpose.—Mr. H. Deacon, on "Deacon's Method of Obtaining Chlorine, as Illustrating some Principles of Chemical Dynamics." The process consists in passing a heated mixture of air and hydrochloric acid over sulphate of copper, or over pieces of pumice or brick saturated with the same. He finds that the action is essentially a surface action, and that there is a certain comparatively small range of temperature, between the critical limits of which the percentage of hydrochloric acid decomposed varies greatly. The velocity with which the mixed gases pass over the surface of the active material also causes considerable variation in the comparative amount of chlorine produced.

SENSATION AND SCIENCE

II.

THERE lies before us, as we write, a work of exceptionally high merit as a mere literary composition, entitled, *Ueber die Natur der Cometen, Beiträge zur Geschichte und Theorie der Erkenntniss.* Von J. C. F. Zöllner, Professor an der Universität, Leipzig. The title does all it can to indicate the sensational character of the work, which deals not alone with the nature of comets, the inferiority of British to German physicists, and the grave offence of which a German is guilty when he sees anything to admire except at home; but also with the errors of Thomas Buckle, the relations of Science to Labour and Manufacture, and the analogies of development in Languages and in Religions!

It is impossible for us in a brief article to give the reader even a general glance at the numberless sources of amusement which the work affords. We will, therefore, confine our detailed remarks to a few of the parts which have most interested us, merely premising that we cannot pretend to give anything resembling a complete analysis of the contents of this astounding volume.

The skeleton, or framework, upon which the fabric is supported, consists of some scientific papers by Zöllner, extracted from the Transactions of the Royal Society of Leipzig. Along with these are reprints of the descriptions given by Olbers and Bessel of the Comet of 1811 and Halley's Comet, with the speculations of these great astronomers as to the nature of the forces under which the various parts of a comet move, especially with regard to the supposed repulsive force exerted by the sun on the matter of the tails of all comets but the smallest, and by the heads of the large comets upon their tails.

We must not pause to criticise these speculations, else we should be treating of Science, extremely hypothetical no doubt, but still Science; whereas we have undertaken to give the reader some information about the progress of the *Sensational* in Science. But there is one remark which must be made. Prof. Zöllner is loud in his denunciations of Sir J. Herschel's remarks on comet's tails, especially where he says in his "Outlines of Astronomy," "There is beyond question some profound secret and mystery of nature concerned." On this Zöllner remarks, "Could Sir J. Herschel have foreseen what mischief his mystical comparisons about comets were to do to the brains of his countrymen he would certainly have refrained from employing them." But with marvellous consistency he shortly afterwards quotes with approval the following passage from Olbers, as far as we can see quite as strong as anything of Herschel's:—"The particles which we see glittering in the comet's tail are thus not always the same. No; incessantly from its nucleus and from its proper atmosphere new materials develop themselves, and stream off from the comet with astounding (*erstaunenswürdig*) velocity to be lost in the vast expanse of heaven."

We must confess that the perusal of the *scientific* part of Prof. Zöllner's work has not impressed us with the highest respect for his originality or even his exactitude. "Who drives fat oxen should himself be fat;" so that when we found Sir W. Thomson, Helmholtz, and Hofmann figuring everywhere among his playthings, we eagerly looked to his original paper, the kernel of the volume, for something of the very highest order of mathematical and experimental inquiry. But, alas, in vain! We found some ordinary "second-year" mathematics (not always correct) and *one* sole experimental illustration, of a ludicrously obvious case of Newton's Third Law of Motion! Any mathematical student should surely know, that it does not require profound knowledge to calculate the distribution of gas or vapour about a spherical body if the law of attraction and that connecting pressure and density be assigned. But we must again recollect that our business at present is not with science, even the feeblest, unless accompanied by sensation.

Our difficulty now lies in selecting. Hundreds of racy passages must be omitted, else we should exceed all endurable limits. For, after the nucleus of the work, comes a long and ferocious attack upon *John* (*sic*) *Tyndall's Cometen-Theorie*, which may in the natural course of events draw down on poor Zöllner a castigation he will never live to forget. In the words of Bürger, who imagined his prototype in a much less perilous position—

> O Zöllner! O Zöllner! Entfleuch geschwind.

It is drawn up in heads like a catechism, and is at least as metaphysical; but we have almost enough of it in the first of these heads, which we do our best to translate as "The fountain head of scientific knowledge, and its practical signification." A perfect volley of *Continuität, Schamgefühl, Individuum, Causalität, Theorie der Erscheinung, Lust und Unlust*, &c., all in italics, fills many subsequent pages. We have not read them, save so far as to see (by a cursory examination) that Prof. Zöllner employs language no doubt intended to be bitterly sarcastic, but which is so savage as to defeat its purpose, and which would be utterly unjustifiable, even if his half-made, half-implied, accusations had any foundation in fact. Section 13 has the appalling title, "Allgemeine Ursachen abnormer Erscheinungen begründet im Zeitgeiste. Verhältniss der Wissenschaft zur Technik und Industrie." Like a true Mephistopheles the author next confesses that he is tired of this dry tone, and must bring his victim (the reader, poor wretch) into merry company, and show him how jollily one can live. Whereupon he rises into the third heaven of vapulatory eloquence about the *Hofmann-Feier zu Berlin*. This seems to have been a sort of scientific high-jinks, perfectly harmless from every point of view. But Prof. Zöllner is a realisation in the flesh of Sydney Smith's ridiculously inapt description of a Scotsman, he cannot see a joke—perhaps even the surgical operation would be thrown away upon him.

We next come to a mighty chapter, headed "Aphorismen zur Geschichte und Theorie der Erkenntniss." Here we get back again to the "trocknen Ton" and deal with *Causalität, Causalverhältniss, Lust und Unlust*, &c., more bewilderingly than before; and we find that it appears to the gifted author that "the Phenomenon of Sensation is a more fundamental fact of observation than the

Mobility of Matter." Here we confess we felt nonplussed, and as the rest of the work (pp. 321-523) seems, on a hasty glance, to be of the same sort, varied only by occasional extravagant eulogy of some philosophers and denunciation of others, we leave it unnoticed, except as regards one particular which will afterwards be referred to.

We now come to the richest part of the volume, the preface and introduction, written (as we are told) later than the rest, and therefore when the author had managed thoroughly to divest himself of all the usual amenities, as well as of regard for at least the scientific character of certain living philosophers.

From the introduction we paraphrase as follows (the passage follows some fierce remarks about Dr. Tyndall):—

"I can assert that, when I read the addresses of Sir W. Thomson and Prof. Tait to the British Association, and when on my return to Leipzig I found on my table among the scientific novelties the German edition of their 'Natural Philosophy,' edited by Helmholtz and Wertheim (including particularly section 385), then, indeed, the appearance of my work seemed to be a *Naturprocess*; something necessary in the chain of scientific development, of which even I myself scarce knew how it had arisen, and what was my share in it. In fact, the desire to bring to light in this book what is more or less struggling to appear in German science, what is bringing out a hollow sound now from one string, anon from another; this desire, I say, has been with me to the latest scratch of my pen. I therefore doubt not that, simultaneously with mine, other heads have been working at the same problem, and perhaps in unconscious coincidence have arrived at the same solution. May then such facts ever more forcibly impress us with the conviction that the claims of personal services belong much more to the Age and to the Race than to the individual, and that no ever so clear conscious selection of means can be compared with that wonderful harmony with which Nature seeks to farther, and at the same time more surely to reach, her to us unknown ends."

To understand the bearing of the above passage, which is simply a literal assertion of

Deutschland, Deutschland über Alles,
Ueber Alles in der Welt,

the reader must refer to the preface, where he will find (along with much metaphysics) a war-dance over the mangled scientific reputation of Sir W. Thomson. The celebrated "moss-grown fragments from the ruins of another world" was a joke taken in earnest by many even in this country; so we can hardly blame Prof. Zöllner for falling into the trap; but why "bewachsene" instead of "bemooste" in translating the passage for thy countrymen, O Zöllner? Prof. Zöllner's remarks upon British philosophers as a class must be given in his own words:—"Allein die Speculation ist in der gegenwärtigen Entwickelungsphase der Naturwissenschaft ein so tief empfundenes Bedürfniss, dass selbst hein eut fast nur noch *inductiv* thätiges Volk, wie die Engländer, der Versuchung nicht widerstehen kann, sogar über *mathematisch-physikalischen Hypothesen* zu speculiren."

Then we have the old question about the discovery of Spectrum Analysis, Stokes and Balfour Stewart now coming in along with Thomson for their share of the *grêle de coups*. So severely accurate a judge as Zöllner should, however, have known that Stewart has pointed out that Kirchhoff mistook his meaning when he charged him with error as to the expression for internal radiation in terms of the refractive index. A sentence from Prof. Tait's address to Section A, last August, is used as a sort of weapon against British scientific men. Prof. Zöllner here quotes the part that suits him, leaving out altogether the portion (immediately following) which turns the charge entirely the other way.

Another indefensible style of controversy we must allude to as exhibited by our author. In the above extract from his introduction it will be noticed that he specially alludes to Section 385 of Thomson's and Tait's book. In the preface we find the following condemnation of it, which is calculated to ensure notoriety. "I venture deliberately to assert that in the whole of German physical literature there cannot be found one single text-book which, in the short space of only thirty lines, contains such a plentitude of *absolute* nonsense." It is true there is a jokelet in this (now) celebrated section, something about catching a luminous corpuscle and examining it—it forms the text for a good many severe remarks; but Prof. Zöllner goes further, and accuses the authors of the work of discourtesy to Weber, which certainly no one who understands the original or the German translation (which we have taken the trouble to consult) will find in either.

Whether Thomson and Tait, with Helmholtz and Clerk-Maxwell on their side, or Weber with the assistance of Neumann (and Zöllner), shall ultimately be found correct on a purely scientific question, it is not our present business to inquire; what we do object to is the sensational imputation of discourtesy, if not of something worse, especially when the object of this imagined insult is a venerable philosopher who will undoubtedly leave a permanent mark on the history of his time.

It would next be our task to show how heartily Helmholtz is pitched into for having sanctioned by his name the Geman translation of the work in question, and for his worthy recognition of Sir W. Thomson's scientific discoveries; but enough—Deutschland über Alles, and down with every Deutscher who sees aught to admire or to respect beyond the limits of Germany!

CONCRETE ARITHMETIC

Concrete Arithmetic; an Introduction to the Elements of the Abstract Science of Number. For young Children. By Temple Augustus Orme. (Groombridge and Sons, 1872.)

"SIR, according to the custom of this town, he is of age when he knows how to count up to twelve pence; and he shall answer in a writ of right when he is of that age."* The work before us will not only enable a pupil to do this, but further gives an excellent account of the first six processes enumerated in the old poem †:—

Septem sunt partes, non plures, istius artis;
Addere, subtrahere, duplareque dimidiare
Sextaque dividere est, sed quinta est multiplicare
Radicem extrahere pars septima dicitur esse.

* Year-book of Edward I, A.D. 1292. Salop Iter., edited by Horwood, p. 220.

† The *De Algorismo* quoted from Halliwell's "Rara Mathematica," by De Morgan, "Arithmetical Books," p. 15.

The passage from the one rule to the next is very gradual, but never tedious; there is copious explanation, but yet we think no superfluous verbiage. Every page is to the point, and marks the writer as one who has had practically to deal with the sort of young minds for whom his work is primarily if not solely intended. The book is a thoroughly rational one, though at first sight the reader may think he has stumbled by mistake upon an elaborate treatise on the subject of dominoes, for the method of teaching is based on a combination of what has been called "palpable" with written arithmetic. In actual teaching the palpable method is the one adopted. Mr. Orme's own words are, "Teachers are strongly recommended to take every available opportunity of using suitable blocks of wood to represent units, tens, hundreds, and thousands, and I should wish it to be distinctly understood that, without these blocks or some substitute for them, the subject will become too abstract to be comprehended by those for whose sole benefit this book has been compiled" (Preface, p. 4); and on p. 7 the resemblance of each diagram to a domino suggests the remark, "Learn to play at the game called dominoes; this will teach you how to tell the number of dots in a figure very quickly."

The main divisions are occupied with units, or single unpacked things; tens, or single unpacked deca-units; hundreds, or single unpacked hecto-units; and thousands, or single unpacked kilo-units. From some of the terms here employed, it might be supposed that the work treats principally of questions concerned with metres, decimetres, and other quantities, which require an acquaintance with the metric system; but this is not the case, though it is well fitted to serve as an introduction to the use of such a system. Special reference to this system is confined to two pages of "Directions," where the dimensions of a square centimetre are represented in a figure.

The following extract from the Preface will serve to show the spirit by which the writer is actuated:—"If the teacher proceeds in this way (*i.e.*, by the palpable method of using blocks) he will be amply rewarded by finding that children, not so stupid as they are often said to be, will frequently make out processes of their own for arriving at truths, having been taught to rely not on rules, but on reason; and occasionally the youngest pupil will unconsciously show his teacher how to teach. . . . . More good will arise from the introduction of a scientific method into the teaching of the ordinary subjects of education than will accrue from object lessons, or the freely-accepted dicta of men of science." In thus letting Mr. Orme speak for himself, we shall best put before our readers the object aimed at in his book—an object which he seems to us to have compassed; and as we think it is a right one, it is on this ground we venture to recommend the work to all who may be in search of a good elementary introduction to arithmetic. If they carefully follow out the advice given, and pursue the plan laid down, they will convey a sound and accurate view of the subject, and that without wearying the young student. There is good store of simple and varied exercises in this handy volume, which may readily be curtailed or enlarged, according to each individual case. The only typographical faults we have to point out occur on pp. 30, 104, and 105, and are readily corrected. We commend the book as the work of a "cunning" arithmetician. "It is pitie that commonlie more care is had, yea, and that emonges verie wise men, to finde out rather a cunnynge man for their horse, than a cunnyng man for their children."*

OUR BOOK SHELF

Contribution to the Biology and History of the Development of the Ustilagineæ. By Dr. A. Fischer von Waldheim. Translated for the Transactions of the New York State Agricultural Society for 1870. From "Pringsheim's Jahrbücher," vol. ii. part 1, 2, 1869. (Albany, New York: 1872.)

THE section of Fungi to which the Ustilagines belong has occupied considerable attention from mycologists during the past quarter of a century. Old notions of the autonomy of species have been dispersed, and at the present time all the old genera are suspected, some are condemned, and not a few amalgamated. The present condition of the classification of the Uredinous Coniomycetes is eminently transitional; so much has been written, so many observations made that await confirmation, or require further researches to render the work complete, that no one would be rash enough to predict what another twenty years may accomplish towards settling the relations of the genera in this group to each other. From the vague notions and doubts of Unger's "Exantheme" in 1833, Leveille's researches in 1839, Tulasne's first memoir in 1847, De Bary's "Brandpilze" in 1853, Tulasne's second memoir in 1854, there has been a regular advance in the accumulation of observations and the record of facts up to the publication of Fischer von Waldheim's communication in 1869. The relations of *Trichobasis* to *Puccinia*, of some species of *Lecythea* to *Melampsora*, of others to *Phragmidium*, are admitted on every hand; but whether *Trichobasis*, *Puccinia*, *Uromyces*, and *Æcidium*, shall all give way to an amalgamated genus, in which the four forms shall be recognised as four conditions of the same plant, though accepted by some, cannot yet be considered as settled beyond a doubt. The more sceptical of mycologists suspend their judgment, and await the confirmation of certain observations. Whatever the result may be, there can be but one opinion that such men as Tulasne, Leveille, De Bary, and others, deserve all commendation for the work they have accomplished. Whilst the Uredines Proper have suffered greatly in the stability of their generic distinctions, the Ustilaginous group has at present maintained its character for the autonomy of its species. Up to the present *Tilletia*, *Ustilago*, *Thecaphora*, and *Urocystis*, seem to represent comparatively stable genera. It is not impossible that this is more *seeming* than *real*, and that future workers may reveal affinities more close than as yet are suspected. The "contribution" of Fischer von Waldheim dates as far back as 1869, although now presented for the first time in an English dress, and we have to thank our Transatlantic cousins for having accomplished this fact. The New York State Agricultural Society is wise to diffuse this and all similar information amongst its members. None are more deeply interested in the development, conditions of growth, and metamorphisms (if any) of the "Smuts" than agriculturists, and to no societies should we look with more confidence for the publication of such memoirs as the present. How far they have accomplished this belongs to the past, and has become history; what they may do in the future lies within their own power. The memoir now published commences with a very good digest of the literature of the subject, after which follow the personal observations of the author on the mycelium and spore

* Ascham, "The Schoolmaster," Book I.

growth in *Tilletia, Ustilago,* and *Urocystis.* The synopsis of the Ustilagineæ in relation to their supporting plants and the place of their spore formation will be very useful to students, as will also the counter-synopsis of the supporting plants, and the Ustilagineæ occurring on them. The details of the germination of spores, direction and character of the promycelia, the effects of moisture, light, &c., measurements of threads and spores, all combine to render this a useful contribution to the literature of the Smuts, although not containing any startling discoveries. It is just what it professes to be, the record of observations on the germination of the spores of several of the Ustilagines under artificial cultivation, as a supplement to Tulasne's memoir in which this history of development was deficient. It would have been an advantage had this "Contribution" made its appearance in the trade as a separate publication with a London publisher, at a fixed price, so that all persons interested in the subject in this country might have obtained copies, and recommended the work to their mycological, horticultural, and agricultural friends.

M. C. C.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Philippine Islands

ENCLOSED you will find :—1. A list of Earthquakes on the Philippine Islands from January to March 1872. As communication is very bad here, and meteorological observations are seldom made and noted down, I may say that most of the earthquakes do not come to our knowledge at all. I believe I do not say too much in expressing my opinion that there may be, at least, one earthquake every day at some one spot in this Archipelago. 2. Description of a Typhoon, which I witnessed at Cebu.

EARTHQUAKES ON THE PHILIPPINE ISLANDS

Since my last communication to the list of earthquakes to your journal (Feb. 5, 1872) I have noted the following :—

1872

Jan. 27, Zambales in Luzon, E.-W., many and strong shocks.

Feb. 7, Camarines on Luzon, twice.

Mar. 5, Manila, weak, 9 A.M.
6, Province Laguna in Luzon, 9 A.M. } These two were perhaps on the same day, and a mistake has been made in the letter which announced the second.

22, Manila, several very strong shocks.

,, Province Batangas in Luzon.

TYPHOON AT CEBU

April 4, I witnessed a Typhoon in the harbour of Cebu, Philippine Islands, on board H.M.S. *Nassau,* Captain Chimmo. The following gives a short description of it, hoping that the officers of that ship will publish a detailed account of this interesting storm :—

		Barometer	
8h	A.M.	29·96	Strong N.W. winds, heavy rains.
2h	P.M.	29·82	
3h30m	,,	29·74	
6h	,,	29·54	Wind, N.W. (4 to 8) rain.
7h	,,	29·40	Wind and rain ceasing, till
8h	,,	29·30	some heavy squalls from N.W., followed by perfect calm.
8h15m	,,	29·28	Lowest marking of the barometer, till most furious squall from S.E. (11) with heavy rains and lightning. This furious storm lasted about ten minutes, and then, varying from S.E. to S.W. (hardest from S.) diminished slightly; barometer rising rapidly.
10h	,,	29·76	Wind steadier, squalls less frequent, and heavy rain ceased.
12h	,,	29·86	Wind steady from S.S.E. (5) dying away till daylight.

About eighteen vessels were thrown on shore, more or less damaged, many houses unroofed, and native huts blown away throughout the island Cebu, and several lives lost. At Iloilo in Panay the storm did a great deal of damage too; at Manila it was not observed at all. It is said that there must have been at the same time a storm at Sargoon. Typhoons are very rare as far south as Cebu, and are said not to have been observed for twenty years. This storm proves to be a real typhoon, according to the variation of the wind and the calm betwen it, showing that the centre passed Cuba.

Manila, April 15 ADOLF BERNHARD MEYER

The Conservation of Energy not a Fact, but a Heresy of Science

PERMIT me a few words in reply to Mr. Brooke's strictures in your journal (No. 137) upon my article on "The Heresies of Science" in the *London Quarterly Review* of July last.

Mr. Brooke asserts that in the article "two widely different principles are oddly linked together as heretical dogmas, the doctrine of Evolution and the Conservation of Energy." Now, so far from these doctrines being oddly linked together as heresies, they are not linked at all. It is not the doctrine of Evolution, but the hypothesis of Natural Selection that I affirm to be one of the great heresies of modern science. Evolution is dealt with only so far as is found necessary to prove that the theory of Natural Selection is false. The two heresies named are connected in the article because I found so many physicists employing them to overthrow some of the best established truths in philosophy. Of this Mr. Brooke is perfectly aware, since he expresses regret that "the principle of the Conservation of Energy has by some been misapplied in a fruitless endeavour to supersede the necessity of a creative intelligence."

"The Conservation of Energy a Fact, not a Heresy of Science," is the title of Mr. Brooke's paper. To this assertion I need only oppose some of his own admissions. He complains that the proposition—viz., "that the amount of energy in the world is unchangeable, the sum of the actual or kinetic and potential energies being a constant quantity—has been by some writers rather overstrained." "It may," he adds, "be taken as a postulate, and is probably true, but it is a proposition that is equally incapable of proof or of disproof, because the amount of potential energy in a body can be determined only by its development into actual energy, and cannot therefore be predicated."

Are then our judgments respecting that which Mr. Brooke asserts to be a fact of science only probably true? Surely there is contradiction here. I take it that science is knowledge, and that consequently judgments not accompanied by a conviction of certainty, but merely possessing a higher or lower degree of probability, are altogether outside the sphere of science. As Mr. Brooke accepts the doctrine of the Conservation of Energy as a truth of science, it is not competent for him to maintain that the proposition—viz., "that the amount of energy in the world is unchangeable, the sum of the actual or kinetic and potential energies being a constant quantity"—is equally incapable of proof or disproof, unless he can show that it expresses one of those primary convictions of the mind which constitute the very starting points of human thought. Let Mr. Brooke do this, and there is an end to all discussion on the subject. By one of the laws of thought a proposition which can neither be proved nor disproved, but by other propositions not more evident or more certain, must, by all rational minds, be accepted as true. In this region doubt becomes suicidal by self-contradiction. It is easy to show that the proposition which constitutes the scientific expression of the doctrine of the Conservation of Energy is not the symbol of a primary synthetical judgment. It is really nothing but a truism rendering to the scientific inquirer no higher service than the statement that "every effect must have a cause." In all such cases we grant the truth of the proposition when we grant the definition of either of its related terms. "That everything which begins to be has been produced, immediately or mediately by the power of an intelligent being," is the only philosophic expression of the great law of causation. Stated thus it becomes the appropriate symbol of a primary and necessary synthetical judgment of which every sane mind is conscious. No less a thinker than the late Sir John Herschel held that the doctrine of the Conservation of Energy is a mere truism. It is so as the result of the introduction of what he terms the unfortunate phrase "potential energy."

Mr. Brooke says that "energy is the power of doing work." He does not tell us what he means by work. If he means motion in any of its modes, then he confounds what he holds to

be distinct realities, viz., Force and Energy. Further, he states that "the term 'potential' applied to Force or Energy means inactive, but capable of being called into action. Thus, if a weight be raised, a certain amount of energy is expended in raising it, and so long as the body is supported the energy expended in raising it remains potential in it, but when allowed to fall freely *in vacuo* to the level from which it was raised, the body acquires exactly the amount of energy that was expended in raising it." This too is the view of Tyndall and Balfour Stewart. According to this doctrine, if I throw a stone upwards, say to the height of twenty feet, the energy expended is not lost, but gradually changed in form as the stone ascends. When the stone leaves the hand its energy is actual, at its maximum height it is potential. As a form of potential energy it is a kind of power existent in the stone, but unexerted until the stone begins to descend. According to the theory of conservation this unexerted power is not a reality which abides in the stone by virtue of its constitution, but a power that may be lost, and lost as quickly as it was gained. When the stone reaches the ground it possesses no energy beyond a portion of the heat generated by the collision. The advocates of the conservation hypothesis tell us that the potential energy of the stone at its maximum height is a power to do work. We inquire what work, and are gravely assured that the stone has power to fall, which it could not do when it rested upon the ground! Let us suppose that when the stone leaves my hand I was standing on a covered coal-pit two thousand feet deep, and that I remove the cover as the stone descends, if, as Mr. Brooke affirms, the Conservation of Energy is a fact, it follows that when the stone has fallen through twenty feet it will remain suspended over the pit. By its ascent it acquired power to fall only twenty feet, not two thousand and twenty feet. The metaphysicians, so much belaboured by Prof. Tait and other physicists, have ventured to think that the force of gravity has something to do with the fall of the stone. I have certainly found myself unable, even with the aid of the scientific imagination, to form an intelligible idea of the reality supposed to be symbolised by the term "potential energy." The theory of the Conservation of Energy as now maintained by physicists is opposed in several respects to the doctrine of the conservation of force as held by Faraday. Stewart, Brooke, and others teach most explicitly that energy is not only constantly changing its form, but always shifting about from one portion of matter to another. If I mistake not, Faraday asserts the very opposite respecting force. He seems to teach that each material particle, into whatever combinations it may enter, retains all its original forces. "A particle of oxygen," he says, "is ever a particle of oxygen."

Mr. Brooke makes other admissions which are as inconsistent with the truth of the doctrine of the conservation as the one I have examined. These, however, I must leave for the present. I feel that the most satisfactory reply to Mr. Brooke's strictures would be to quote here, with two trifling exceptions, the portion of my article which relates to the conservation of energy. Those exceptions I will now name. First, I withdraw what I have said respecting Mr. Brooke's view of the nature of latent heat. My sole reason for not in this connection quoting more was that I had assumed his perfect agreement with Prof. Tait. In this it seems I was wrong, since Mr. Brooke declares that he is unable to derive any definite idea from Prof. Tait's statement. I am sorry that Mr. Brooke should have supposed that the omission of the sentence named was due to a lack of literary honesty. I wonder that it did not occur to him that another and more charitable explanation was possible. Secondly, I was in error as to the weights employed by Dr. Joule in one of his experiments for determining the mechanical equivalent of heat. But this error relates merely to the form, not to the ultimate result of the experiment; and consequently in no way invalidates my reasoning. Holding, as I do, that forces are both conserved and correlated, I feel no difficulty whatever in accepting the facts established by Dr. Joule. He avoids speculation regarding the nature of force in itself, and deals exclusively with its manifestations. Thus, his discovery of "the mechanical equivalent of heat" is the discovery of a relation between two classes of effects.

There is one misrepresentation in Mr. Brooke's review of my article I must here point out. He says, "the reviewer thus quaintly expresses the relations of force, energy, and motion:—A given motion viewed as a cause is force, while the very same motion thought as an effect is energy." But this is not my doctrine. I am here dealing with the consequences of one of Mr. Justice Grove's assumptions, viz., that if we attempt to analyse our conception of force, viewed as the cause of any perceived motion, we can get nothing beyond some antecedent motion. Mr. Brooke complains that the misapplication of the term "force" has led to great confusion in physics. His own statements are nevertheless unsatisfactory, if not contradictory. He accepts the definition of force given by Faraday. But this so-called definition by Faraday is not definition at all. It merely tells us what force does, not what force is. Mr. Brooke adds that the definition "may perhaps with advantage be thus amplified:—Force is a mutual action between the atoms or molecules of matter."

But these molecular actions or motions are the effects of force, but not force itself. In no instance whatever can force be resolved into molecular motion. Mr. Brooke says, "One finds oneself occasionally brought by circumstances into an unwelcome generalisation. Thus the reviewer, speaking of the supporters of 'conservation' in the lump, says 'they take it for granted that force is motion and nothing but motion.' This the writer entirely and absolutely denies." Will Mr. Brooke show that this denial is in harmony with his assertion that "force is a mutual action between the atoms or molecules of matter?" I cannot. My reasons for rejecting the assumptions on which the doctrine of the conservation of energy rests are not noticed by Mr. Brooke. These assumptions I have shown belong to false and exploded metaphysics." A false philosophy of causation, it is easy to prove, has greatly retarded the progress of science.

I perceive that Mr. Brooke has used for reference one of a small number of copies of my article printed for private circulation. Unfortunately the paging does not correspond with that of the review. Had I only anticipated the pleasure of an encounter with Mr. Brooke, I would gladly have sent him the review itself. As Mr. Brooke is aware of what passed at a very recent meeting of the Victoria Institute, I cannot longer withhold my name.

Sale, near Manchester, June 26 JOHN MOORE

Water Analysis

IN NATURE for June 27, 1872, Mr. Wanklyn directs attention to the facts that his paper on water analysis appeared in 1867, and that in 1868 he gave some absolute errors obtained with his process.

Mr. Wanklyn then proceeds to say:—"We have never said that distillation of albumin with alkaline permanganate converted the whole of the nitrogen of the albumin into ammonia. The assertion in your article is therefore untrue." Mr. Wanklyn's ideas of truth are probably peculiar, for if he will refer to his paper of June 20, 1867 (Chem. Soc. Jour. vol. v. N.S. p. 448), he will find the following:—"Direct experiments in which a known quantity of urea, gelatin, and albumin were taken, have shown that all the nitrogen in these substances is obtainable in the form of ammonia when they are subjected to the treatment about to be described, and has disclosed the very singular fact that boiling with a caustic alkali liberates one-third of the nitrogen, both of albumin and of gelatin, in the form of ammonia, and that a subsequent boiling with permanganate of potash liberates the other two-thirds."

Not a word is said in the paper about carrying on the permanganate treatment to dryness, and the only reference to such treatment is on page 450, where it is stated that boiling to dryness with potash alone causes the evolution of a "full third" of the nitrogen as ammonia.

THE WRITER OF THE ARTICLE

Scintillation

CAN any of your scientific correspondents tell me whether the following observation has been published, and, if so, where?

By very slight squinting, or (as suggested to me by a friend) by a slight pressure on one eye, we obtain two images of a star as viewed simultaneously from two stations a few inches apart. We made the experiment some nights ago, and could detect no relation whatever between the scintillations of the two. This seems to explain how little trace of the phenomenon remains when a telescope is used, for in that case we have a sort of integration performed over the whole aperture of the object-glass.

G. H.

To Entomologists

HOW often is it that the entomologist has to regret the want of his net? The rare butterfly, by some curious perversity, is

certain to be seen when the net is not at hand. How, under such circumstances, is the butterfly to be caught? I reply, wait till it settles, and then pick it up. Perhaps most of your readers will reply "Absurd, no butterfly will sit to be caught in that way." Try and see. Whenever the butterfly settles you may walk quickly up to within a short distance from it; the distance will depend on the nature of the butterfly. Arrived at a short distance from the butterfly, the motion must now be slow and even, and as the hand is slowly and steadily advanced towards the butterfly, it will take little or no notice of it, and may be easily picked up with the fingers. In Italy this spring I picked up in this manner both varieties of swallow-tails, as many as five when walking one afternoon. I have also caught in this way, whites, red admirals, painted ladies, peacocks, and many other smaller varieties. This manner of catching butterflies does look suspiciously like the old story of catching birds by putting salt on their tails. Before anyone condemns it, I ask him to give it a fair trial, and I have no doubt he will be astonished at his success. The only thing to guard against is any jerkiness in your motions. All your motions when near the butterfly must be slow and regular. Perhaps the butterfly may not sit long enough for you to approach it by such slow motions. If the butterfly does rise take care not to change your slow and steady motions, and it will take no notice of you, and will often settle again within a few inches of your hand. Often the butterfly takes no notice of you; at other times it seems sensible of danger, but generally contents itself by folding its wings as close as possible, as if to escape notice. When the wings are in this position the butterfly is caught with least damage to its plumage. But in some cases the wings are open. When that is the case I have sometimes folded the wings before picking them up, in order to save the plumage, so tame are they under this treatment. At first I thought it was necessary to approach the butterfly from behind, and keep out of sight as much as possible, but this I find, though an advantage, is not essential. Of course I do not advocate this plan of catching butterflies when a net can be got, as it is much slower and not so certain. Yet it has its advantages. You get the butterfly without breaking its wings or ruffling a feather, and if not a good specimen you can let it away unhurt.

J. A.

ERNEST T. CHAPMAN

MR. E. T. CHAPMAN has met his death by an explosion in his laboratory at Rübeland in the Hartz. A letter containing this sad news has the following particulars:—

"As you are probably aware, Mr. Chapman's work was always in the laboratory, and it was there on the 25th inst. (June) that the accident occurred. On the morning of that day Mr. Chapman had a conversation with the gentlemen here, and shortly after this, at 11 A.M., the bomb-proof building in which he was with three workmen exploded with a tremendous crash. Mr. Chapman may perhaps have informed you that latterly he has been chiefly engaged with the production of nitric methyl-æther, with which he has been making various experiments, and we cannot explain the catastrophe otherwise than that he was not thoroughly aware of the great explosibility of this substance. The workmen present having also all perished, it is unfortunately not possible to obtain any details. The force of the explosion was so tremendous that all the surrounding buildings have been more or less injured, and about ten people seriously wounded."

The substance I presume was nitrate of methyl. If so, this lamentable accident furnishes another proof of the treacherous nature of explosives which, like nitro-glycerine and gun-cotton, contain hydrogen and carbon associated with nitrogen oxides.

Mr. Chapman was only in his twenty-seventh year when his career was thus prematurely closed. A pupil of Hoffmann and Kolbe, he was a prolific author of original researches in organic chemistry. Perhaps the best known of Mr. Chapman's researches is his study of limited oxidation. This process, in his hands and those of others, furnished chemists with a valuable method of chemical diagnosis. The little work on the Analysis of Potable Waters, by Mr. Chapman and Mr. Wanklyn, is a well-known work of reference on this important subject.

Mr. Chapman was an enthusiastic worker. His manipulative skill was of a high order, and his acquaintance with organic chemistry very extensive, his researches in this branch of science being very numerous. If he had lived, and had an opportunity of continuous scientific work, it is impossible to doubt that he would have contributed his quota towards rescuing our country from the too just reproach of rapidly becoming more and more sterile in chemical discoveries.

His intimate friends esteemed him highly, for he was a man of varied culture and singular conversational power. It was always a matter of regret to all true friends of science that a man of such proved ability and promise should have been compelled in a manner to banish himself in order to gain a livelihood. His letters show that even in the remote place of his exile his brain was busy with chemical and physical questions. He must have been killed instantly, and therefore without pain. And certainly as a brave and loyal soldier of science slain on the battle-field of the laboratory, his death, like his life, showed his unwearied devotion to science. We can ill afford to lose such men.

FREDERICK GUTHRIE

DR. WILLIAM STIMPSON *

DIED, at Ilchester, Maryland, May 26, of consumption, Dr. William Stimpson, Secretary of the Chicago Academy of Sciences, in the forty-second year of his age.

The announcement of the death of Dr. Stimpson will be received with profound regret, not only by a wide circle of friends here, but throughout the country. Science has lost an assiduous cultivator, the value of whose labours was recognised in both hemispheres.

For the second time in the course of a few years the Chicago Academy is called upon to mourn the loss of an accomplished secretary. Under Dr. Stimpson's energetic supervision, the collections gathered within its walls at the time of the great fire, in magnitude and importance ranked fifth in the United States, and so admirable were his arrangements that they were flowing in from every quarter of the world. Their total destruction on the morning of the 9th of October last was a terrible blow to the secretary. His private losses, too, were beyond computation, embracing as they did a choice scientific library, gathered at different intervals—many of the volumes being out of print, and many of them being presentation copies from the authors—and also all his manuscripts, including those of the Government Japan Expedition, of which he was the naturalist, which were written out for publication, and were copiously illustrated by drawings, many of which were engraved. Thus, in an hour, perished the results of twenty years' unremitting scientific labour.

To show the high estimation in which Dr. Stimpson was held by men engaged in kindred pursuits, it may be stated that, at the instigation of Agassiz, the results of the deep-sea dredgings of the United States Coast Survey were passed over to him for description—a task calling for the most exact and extensive knowledge.

After the terrible calamity to which we have referred, Dr. Stimpson remarked that he had not the heart to attempt to enter upon his life-work again, but would devote all his energies to the restoration of the Academy.

* From the Chicago *Inter-Ocean*. Communicated by Mr. J. Gwyn Jeffreys.

"If," said he, "I live to the ordinary age, I will gather a nobler collection than we have lost." The Smithsonian Institute, which from the first had been the generous patron of the Academy, was ready to transfer to him duplicates; the Museum of Comparative Anatomy, at Cambridge, through Agassiz, its director, had invited him to go there and select from its ample stores what he desired; and learned societies at home and abroad, in response to his appeals, were forwarding to his care copies of their Transactions. Under such auspices, the members of the Academy felt that its losses would soon be restored, and that its prestige would be more commanding than ever before. They now feel that in the death of their secretary they sustain a loss which is irreparable.

Dr. Stimpson had for some years the premonitions of the disease to which he has just succumbed. Two years ago he passed the winter on the Florida coast, making extensive collections of the flora and fauna of that region. The moist, warm breath of the ocean, he thought, invigorated him. Last autumn he repaired, in company with Dr. Veille, to the same region, embarking on board one of the Coast Survey steamers to superintend the deep-sea dredgings; but he had returns of hæmorrhage, which so far prostrated him as to defeat his purposes. For seventy days he remained on board, with nothing but ship fare to eat, at which his stomach revolted. Gaining the land, he was transferred to a hotel, but his physical powers were past the rallying point. Accompanied by Dr. Veille, he was at length placed on board a steamer, which landed him in Baltimore, from which place, by a short journey in a carriage, he was conveyed to Ilchester, where reside his wife's friends. Here he lingered a few weeks, dictating letters and pencilling short ones to his most intimate friends. And now comes the intelligence that the grave has closed over him, and that in his dying hours his thoughts centred on the Academy.

Dr. Stimpson had qualities which attracted, by the strongest ties, all who had personal relations with him. Modest and retiring in his disposition, the casual acquaintance little knew the vast range and the minute accuracy of his information—information gathered not simply from books, but from personal observation in every quarter of the globe. He has published enough already to create for his name an honourable place in the scientific opinion of the world; but if the full results of his labours could have been brought out, few scientific men in the country would have occupied a more commanding position.

J. W. F.

THE CEYLON ELEPHANT AT THE OXFORD MUSEUM

THERE has just arrived at the Oxford Museum the skeleton of a full-grown male Ceylon elephant. During the visit of the Duke of Edinburgh to Ceylon there were two elephant drives, or kraals, held, of which full accounts were given in the daily papers at the time. It may be remembered that at one of these kraals a large male elephant, a rogue, was driven into the terminal enclosure, together with several other smaller wild elephants. The rogue charged the tame elephants introduced amongst the wild ones, knocking them over repeatedly, and effectually preventing the process of noosing. It was at length found necessary to shoot him, in order that the remainder of the elephants might be secured.

The Governor of the island, Sir Hercules Robinson, desired that the skeleton of the animal should be preserved, and the Hon. P. C. Layard undertook the task. The elephant was covered slightly with earth, so as to protect the bones from rapacious birds; and the mound thus formed was fenced round to keep off jackals, &c. As soon as the bones were cleaned, they were collected and transported to Colombo. Mr. Layard, with his well-known zeal for the promotion of science, took immense pains that the small bones should not be lost, and the skeleton is wonderfully perfect considering the great disadvantages under which it was prepared.

The bones were presented by Sir Hercules Robinson to the Oxford Museum, and all expenses of preparation and packing were defrayed by the colony. The skeleton was packed in two rum puncheons, under my superintendence. In packing heavy bones such as these for a long sea voyage great care must be taken, as, unless they are securely wedged into their places, they will grind against one another and get spoiled. There is nothing better than a cask for packing bones. Straw bands should first be wound round each of the large bones, and, the head having been taken out of the cask, these large bones should be jammed in as closely as possible. The interstices should be filled with smaller bones and straw, which latter should be rammed in tight with sticks. As soon as the cask is quite full the head should be put in, and that end strained up tight with its hoops. The other end of the cask should now be turned uppermost, the hoops knocked off and the bottom taken out. It will be found that a good many more bones may now be introduced from this end, which must be rammed quite full like the other. By thus packing a cask from both ends, almost absolute immobility may be secured for the contents. The elephant's skeleton is a very fine one, and I believe the only one in England of a wild specimen. The ordinary museum specimens are all from menagerie animals, the muscular ridges and tuberosities of the bones of which are always badly marked. The elephant had what is called a tush, *i. e.*, a small short tusk on the left side. This tush is in the collection of the Duke of Edinburgh.

With the elephant arrived a Dugong, also presented to the Oxford Museum by Sir Hercules Robinson. The animal, which is a young one about 5 ft. long, was procured by Mr. Twinam, Government Agent at Jaffna. It was filled with salt and packed in charcoal. It has remained more than a year thus packed up, and is unfortunately in a very pulpy condition, although its external form is remarkably well preserved. Mr. Robertson hopes, with care, to be able to make a skeleton of it.

A case containing some human skulls, and the skeletons and skulls of various smaller animals collected by me in Ceylon, arrived at the same time; and a fourth case, containing skulls of all the non-European races now inhabiting Ceylon, including some of undoubted jungle Weddo, collected by Mr. B. Hartshorne, of Panwila, and late of Pembroke College, Oxford, who has for a long time been investigating the language and habits of this very interesting race, and will shortly publish a paper on the subject.

The shipping arrangements of all the cases except the last, and their transmission through the Custom-house, were carried out by Messrs. Green and Co., of Colombo, who most liberally gave their services free of expense in the cause of science.

H. N. MOSELEY

SUPERFLUOUS DEVELOPMENTS AND HETEROGENESIS

THE remarkable and suggestive results of experimental research obtained by Prof. Charlton Bastian, together with the no less striking arguments which he has recently put forth in the pages of the *British Medical Journal* in favour of the doctrine of Evolution, appear calculated to throw light on certain phenomena in Biology which have hitherto received but scant attention. Even if Dr. Bastian's views do not gain general acceptance, so bold an enunciation of them can scarcely fail to be productive of the very best results, since (as has ever been held by philosophers) truth is only elicited and advanced by conflict of opinion.

Not merely in the lower, but also in the higher forms of animal life the microscopist is constantly encountering anomalous appearances, structures, "bodies," &c.; some of these developments being regarded as normal, whilst others are relegated to the category of pathological products. In very many cases the mysterious organisms in question have been described as "glands;" the variable character of this system of structures affording a convenient refuge for the destitute. More astute observers, however, refuse to adopt such subterfuges, and have accordingly been satisfied either merely to note their characters without forming any definite conclusions, or they have gone only a step further by placing them within the territory of superfluous developments.

To take a few familiar instances occurring within the domain of helminthology. We have the so-called Raineyan sacs, regarded as the earliest stages of Cysticerci by their discoverer. Similar bodies were previously described as the products of muscular degeneration by Hessling. Finally, they were pronounced by Leuckart to be psorosperms. In the year 1856 I detected granular bodies in the early stage of development of the eggs of *Tæniæ*, respecting the nature of which I had then no means of forming any definite opinion. These were subsequently described by Weinland and Leuckart; the latter authority looking upon them as masses cast off from the primitive yelk, and thus differentiated to form an organ concerned in the production of the chitinous envelope of the egg. Then, again, Leuckart speaks of certain "croupy masses" (resulting from the enteritis produced by *Trichinasis*) as capable of resolving themselves into psorospermiæ: and I have myself witnessed what I presumed to be the actual conversion of the granular and molecular contents of the eggs of *Fasciola hepatica* into amœboids. Leuckart, however, from prior and independent observation, had considered these bodies to be the parasitic confervoid zoospores of *Chytridium*.

Undoubtedly, appearances of this varied description are very puzzling; not so much, however, in the view of determining their actual character and nature as for the correct interpretation of their true mode of origination. Perhaps, if one were not, in a measure, dominated by the preconceived idea that these last-named bodies must have sprung from invisible germs, the apparent ocular evidence to the contrary would at once be held as a sufficient explanation. Be this as it may, I may refer in this connection to some interesting facts which have recently been recorded by Profs. F. Sommer and L. Landois. To their interesting "Beiträge zur Anatomie der Plattwürmer" I shall again have occasion to allude for other purposes, but for the present I merely quote the following short passage. Speaking of structures observed in the segments or proglottides of *Bothriocephalus latus*, they say (p. 16):—

"On a level with the folds of the seminal ducts, either close to or lying between them, we observed in the majority of instances within the sexually mature segments round or oval hollow spaces from 0·055 to 0·288m. in diameter.* Their margins were sharply defined, most of them being filled with a finely granular molecular mass; in others the contents appeared coarsely granular, highly refracting. In an especial manner carmine tinctured the finely granular contents vividly red, whilst the coarse granules effected the reduction of osmic acid (*Ueberosmiumsäure*) in a very marked degree; on the other hand the reduction by the fine granules was less marked. Further research showed that these granules consisted of very minute fat particles which, since they were little affected by the direct application of ether, appear to possess an albumenoid covering capable of being slightly tinctured by carmine. We did not observe any of these formations in immature joints; their number also varied much in the ripe segments; of such we counted from one to six in a joint; other sexually mature proglottides being altogether free. They appeared especially in the neighbourhood of the lower end of the seminal duct in front and behind, where the seminal passage approaches the cistern-like seminal reservoir. We regard these formations as detached portions of the seminal canal, namely, of the larger ducts, whose contents are in a state of fatty degeneration."

* About $\frac{1}{400}$″ to $\frac{1}{80}$″ Eng. measurement.—T. S. C.

Such are the facts. Are the bodies in question really pathological products, or are they not, rather, superfluous developments? It cannot be said they are necessary constituents of the parasite; and it will, perhaps, be denied that they are in any sense heterogenetically formed organisms. At all events, these cast-off bodies have a gregariniform look about them, judging from the representations given by Drs. Sommer and Landois. The expression "hollow spaces" (*Hohlraüme*) is certainly rather misleading; the more so since they are rendered somewhat opaque by the crowding of their granular contents

If it be true, as some teach, that protoplasms only beget their own kinds of protoplasm, one is at a loss to understand many of the ordinary phenomena of metamorphosis. for myself, I look upon certain of these obscure developments as the result of a law of what I term "vegetative deterioration." Under ordinary circumstances (as for example in the case of the "innovations" produced from abortive prothallia in Ferns) the law of Pangenesis ensures a repetition of parts in all respects similar to those whence the buddings have arisen; but surely it is not necessary to regard all anomalous and detached structures either as morbid products on the one hand, or as germ-begotten entities on the other. Without letting the imagination run wild, it appears to me perfectly conceivable that "bodies" of a kind more organised than Drs. Sommers' and Landois' "formations," may result from the operation of this law of degradational metamorphosis or "vegetative deterioration."

T. SPENCER COBBOLD

DR. LIVINGSTONE'S DISCOVERIES

FROM Mr. Stanley's despatches to the *New York Herald*, which, by the courtesy of the English representative of that paper, have appeared in the *Times*, we gather some important and definite information as to the exact nature of Livingstone's discoveries; and more than this, we have a full explanation of the circumstances which kept our great traveller so long out of the reach of civilisation, and of the work he still hopes to accomplish

Mr. Stanley's account of his meeting with Livingstone is a touching one. After many delays, on the 3rd of November, 1871, he came in sight of the outlying houses of Ujiji, and, anxious to enter the African town with as much *éclat* as possible, he disposed his little band in such a manner as to form a somewhat imposing procession. At the head was borne the American flag; next came the armed escort, who were directed to discharge their firearms with as much rapidity as possible; following these were the baggage men, the horses, and asses; and in the rear of all came Mr. Stanley himself. The din of the firing aroused the inhabitants of Ujiji to the fact that strangers were approaching, and they flocked out in great crowds, filling the air with deafening shouts, and beating violently on their rude musical instruments.

As the procession entered the town Mr. Stanley observed a group of Arabs on the right, in the centre of whom was a pale-looking, grey-bearded, white man, whose fair skin contrasted with the sunburnt visages of those by whom he was surrounded. Passing from the rear of the procession to the front, the American traveller noticed the white man was clad in a red woollen jacket, and wore upon his

head a naval cap with a faded gilt band round it. In an instant he recognised the European as none other than Dr. Livingstone himself; and he was about to rush forward and embrace him, when the thought occurred he was in the presence of Arabs, who, being accustomed to conceal their feelings, were very likely to found their estimate of a man upon the manner in which he conceals his own. A dignified Arab chieftain, moreover, stood by, and this confirmed Mr. Stanley in his resolution to show no symptoms of rejoicing or excitement. Slowly advancing towards the great traveller, he bowed and said, "Dr. Livingstone, I presume?" to which address the latter, who was fully equal to the occasion, simply smiled and replied "Yes." It was not till some hours afterwards, when alone together, seated on a goat skin, that the two white men exchanged those congratulations which both were eager to express, and recounted their respective difficulties and adventures.

Mr. Stanley's statement is that Dr. Livingstone appeared to be in remarkably good health, stout and strong, quite undismayed by all that he had gone through, and eager only to finish the task he had imposed upon himself.

Dr. Livingstone's story of his adventure was to the following effect:—In March 1866, he started from Zanzibar. The expedition which he led consisted of twelve Sepoys, nine Johanna men, seven liberated slaves, and two Zambesi men—in all thirty persons. At first Dr. Livingstone travelled along the left bank of the Rovuma River; but, as he pursued his way, his men began to grow disaffected and frightened, and, in spite of all his efforts to manage and keep them together, most of them left him and returned to their homes, spreading everywhere the report of his death as a reason for their reappearance there. In August 1866, he arrived in the territory of Mponda, a chief who rules over a tribe living near the N'yassa Lake; and here Wikoteni, a *protégé* of the Doctor's, insisted upon being absolved from going any further. After resting for a short time in Mponda's ground, Dr. Livingstone proceeded to inspect the "heel" of the N'yassa Lake; and it was while carrying out this enterprise that the Johanna men, who had till now remained faithful, deserted him. In December 1866, having collected a number of natives, Dr. Livingstone decided upon advancing in a northerly direction; and, in pursuance of this determination, he traversed the countries of Babisa, Bobembene, and Borunga, as well as the region of Londa.

Approaching King Cazembe's territory, he crossed a thin stream called the Chambezi; and here he found himself in great difficulty, being for a long while unable to discover to what the river belonged. The confusion which he experienced was greatly increased by the fact that Portuguese travellers had previously reported the existence of such a stream, and had asserted that it was a tributary of the great Zambesi river, having no connection whatever with the Nile. These statements Dr. Livingstone was disinclined to believe, and, determined to satisfy himself as to the rise and falling of the Chambezi, he made up his mind to devote himself to the task at once. From the beginning of 1867 to the middle of March 1869, he traversed the banks of the mysterious stream, tracing it where it ran, correcting the errors of the Portuguese travellers, and proving conclusively that the Chambezi was not the head of the Zambezi river, as had been hitherto supposed. So constantly did he remain at this work, and so frequent were the inquiries which he made in every direction, that the natives, in astonishment at his persistence, supposed him to be insane; and their frequent remark was, "The man is mad; he must have water on the brain." Their ridicule had, however, no effect upon him, for he continued his work in spite of every opposition, and as the result of his labours in this region, coupled with his further researches, he has established conclusively (1) that the Portuguese Zambezi and the Chambezi are totally distinct streams; and (2) that the Chambezi is the head waters of the Nile. He found that starting from 11° south, the River Nile rolled on until it attained the extraordinary length of 2,600 miles.

In the midst of his wanderings Livingstone came upon Lake Liemba, which he discovered to be fed by Lake Tanganyika. His map of the last-mentioned lake shows that the southern portion of it resembles in shape the lower part of the kingdom of Italy. He found that it rises in 8° 42″ south, is 325 miles in length, being thus seventy-three miles longer than was supposed by Captain Burton and Captain Speke. Leaving Tanganyika, the Doctor crossed Marungua, and came in sight of a small lake, called Lake Muero, which he found to be six miles in length, and to be fed by the Chambezi. In his way he traced the Chambezi running through three degrees of latitude, and having thus satisfied himself of the total independence of the Zambezi, he returned to King Cazembe's country, and then made his way to Ujiji, where, early in 1869, he wrote letters and despatched them by messengers. A short rest was made at Ujiji, and having explored the head of the Tanganyika lake, and thus finding out that the River Rusizi flowed into the lake, and not out of it, as had been supposed, he made preparations for another, and as he then hoped, a final journey of exploration.

Leaving Ujiji in June 1869, he pushed through the Uguhba country, and after fifteen days' march he came to Mamgema, which he found to be a virgin country, the interior of which seemed utterly unknown to anybody. As he was about to proceed, however, he was seized with an illness which at one time almost threatened to put an end to his explorations. Ulcers formed in his feet, and for six weary months he was obliged to rest and wait. As soon as he had recovered he started off in a northerly direction, and came shortly afterwards to a broad river called Lualaba, which flowed in a northerly, westerly, and southerly direction. Strongly suspecting that this river was but a continuation of the Chambezi, which enters the Banguereolo, Luapula, and Muero lakes, he retraced his steps to Lake Kamolondo, and thence working his way to lat. 4° south, and after a long and difficult journey, he found the point where the Lualaba and Chambezi joined, and proved them to be both one and the same river.

He followed the course of the latter river for several hundred miles, and had come within 180 miles of that part of the Nile which has already been traced, when the men he had with him mutinied, and deserted him. Having now neither stores nor followers, he was obliged to retire to Ujiji, weary and destitute. It was soon after this that Mr. Stanley found him. In fact, the English explorer arrived at Ujiji on the 16th of October, 1871, and it was, as already stated, no later than the 3rd of November when the American searcher made his entrance into Ujiji.

On Nov. 20 Dr. Livingstone and Mr. Stanley left Ujiji in company, and explored the northern end of Lake Tanganyika, confirming by a second inspection the observations which Dr. Livingstone had previously made; and after 28 days thus pleasantly spent, they returned to Ujiji, and there passed Christmas Day together. On Dec. 26 they left for Unyanyembe, and, arriving there, stayed together till March 14, when Mr. Stanley, intrusted with letters from Dr. Livingstone, started for the coast, leaving the explorer to continue his searches for some time longer.

Dr. Livingstone states that he considers he has yet two problems to solve in connection with the Nile. The first, the complete exploration of the remaining 180 miles which lie between the spot where he was compelled to turn back and the part already traced; and he should investigate the truth of a report which has several times reached him respecting four fountains, which he has been told, supply a large volume of water to the Lualaba. To complete this task, Livingstone estimates that he will require sixteen or eighteen months. Mr. Stanley, however, is of opinion that it will occupy a longer period.

*MY GARDEN**

WITHIN about twelve miles of London Bridge as the crow flies, at Beddington, in Surrey, Mr. Smee has a garden, and the description and history of this garden are the subject of as pretty and entertaining a book as we have met with for a long time. In thus describing the book, we advisedly use terms which do not imply that it has any great scientific value in the sense of being the medium of publication of new facts; nor, indeed, does it put forward any such pretensions. Mr. Smee, whose reputation as an original investigator in electrical science, and as the inventor of the galvanic battery which bears his name, is thirty years old, is in the domain of natural history essentially an amateur, and the work which he now publishes is an amateur's book. To rank it in the same class as Gilbert White's "Natural History of Selborne" is very high praise, but in some respects it certainly deserves it. Faults the book undoubtedly has; some would call it egotistic, but it is a kindly sort of egotism, which interests the reader in the author and everything connected with him; and here and there the critical reader will detect a slip betraying want of accurate scientific knowledge; but these are very few compared with the amount of information contained in its pages.

Mr. Smee's garden consists of about eight acres,

Fig. 1.—Valley of Ferns

bounded on one side by an artificial lake, and watered by the river Wandle. When first brought into cultivation the land was a peat-morass; but is now made to produce every variety of scenery that ornamental gardening can display. Here we have umbrageous forest-trees, and here a rustic bridge; here a fern-glen, and here a nightingale bower; here a rockery of Alpine plants, and here a glimpse of beautiful water scenery. Indeed, in looking at the exquisite drawings with which the book is embellished, it is difficult to realise that the scenes they depict can be reached from London in half-an-hour. The following passage, in Mr. Smee's own words, gives his ideas on the proper mode of laying out a garden:—

"It is a common notion that gardens should be laid out for one general effect; but the result of such a plan is to produce a single view, and the whole can be seen at a glance. This is, however, monotonous, and my liking is to have many pictures; so that my visitors have to walk a long way before they can see the many beautiful views which my garden affords; and little spots of cultivated wildness, or of special cultivation, are found when they are least expected.

* "My Garden: its Plan and Culture, together with a General Description of its Geology, Botany, and Natural History." By Alfred Smee, F.R.S. Illustrated with 1,250 engravings. (London: Bell and Daldy. 1872.)

"In all my designs, I have tried to suggest to the mind that it must be so; and even when my arrangements are most artificial—as when a walk doubles upon itself—it looks that the arrangement has been made because no other plan was really practicable; and when this idea is carried out, the garden looks natural.

"Throughout my garden my vegetables, flowers, and fruit-trees are blended together in one harmonious whole:

FIG. 2.—SHREW MOUSE

FIG. 3.—THE GOLDFINCH

FIG. 4.—HARVEST MOUSE

a plot of carrots and a row of flowering peas are beautiful objects in themselves, and hence plots of vegetables and fruit-trees alternate with rosaries, ferneries, alpineries, and flower-beds. . . .

FIG. 5.—ROAD NEAR BEDDINGTON

"A long straight line is, in a proper place, very pleasing, and my pear-tree walk is about 150 yards long, parallel with the Park palings. This walk is overarched, at intervals, with climbing roses; and planted on one side with

FIG. 6.—HYMENOPHYLLUM DEMISSUM

FIG. 7.—ADIANTUM CAPILLUS-VENERIS

FIG. 8.—HYMENOPHYLLUM TUNBRIDGENSE

pyramid pear-trees. The general effect is in the highest degree charming, when we come upon it from paths of curved lines, and view the chequered shade upon the ath.

"Again, my fern glade is straight, and has a straight grass walk by its side. The nut bushes, on one side, are parallel with the stream; and the grass walk and rows of apple-trees, on the other side, are also straight. In this

case also it would have looked unnatural to have had curved lines; and, although I once was tempted to try it, and had made preparations for curving the river, I ordered the materials away, so satisfied was I that straight lines alone would look natural for the occasion.

"With the exception of places where straight lines look natural, I eschew them, and also geometric figures, such as ovals, circles, octagons, as not suitable to the horticulturist, and unpleasing to the eye.

"In using curved lines beauty appears to consist in an ever-varying amount of curve. They should be parts of no regular figure, and the Indians have supplied us, in the patterns of their shawls, with forms which ever please us. In arranging them we must be guided by the eye, and frequently a variation of an inch or two makes an important difference in the effect which is produced."

But the charm of the book is the minuteness with which every detail of the garden is described; not only the flowers and fruits grown in it, the varieties which are found to answer best, and the best mode of cultivating them, but the animals, birds, beasts, and insects, which frequent it, or which have been occasionally seen in it. Mr. Smee thus gossips pleasantly about his ferneries:—

"For some years past ferns and ferneries have been much admired, and have received great attention from amateur cultivators; and with good reason, as their graceful forms are most attractive, their mode of growth interesting, and the colour of their fronds enchanting. Ferns should be grown by themselves, and not mixed with other plants, for several reasons, the principal being the necessity of a special situation for them, and their dislike to be interfered with. However, the rhododendron, and especially the scarlet varieties of it, may be planted along with ferns as a fitting accompaniment; a climbing rose growing wild, or a single-flowering scarlet thorn, may also be employed with advantage. Before the fronds shoot out in spring I like to see the ground, in large patches, covered with masses of primroses at one spot, masses of snowdrops at another, masses of the wild oxalis at a third, and at other places carpeted with the wild hyacinth. It is not usual for me to mix these flowers together, as masses of colour, such as these flowers afford in their native woods, give variety to the scenery of the garden. . . . ."

"Experience has taught me that ferns like an abundance of light, although it is necessary to screen them from cold winds. For this reason I always contrive that a belt of trees, or of rootwork or rockwork, shall surround my ferneries, and at the same time that the light of the sky may fall upon them from above without their being directly exposed to the fiery rays of the sun.

"My Fern Glade is placed on one bank of the backwater, and is screened from the sun by a row of nutbushes to the south. Here many of the larger varieties of lady-ferns, interspersed with polystichums, broad ferns, mountain ferns, and scolopendriums, are grown. The royal fern flourishes near the river, but it is advisable to keep the crowns well above the water, as their roots like damp soil rather than wet. In the driest spots we grow polypody (*Polypodium vulgare*), and in the wettest the marsh fern (*Lastræa Thelypteris*).

"The Fern Glen is a more elaborate artistic production, affording many delightful little views and growing fine ferns. The whole is well sunk into the ground, with little rivulets running through, affording one or two boggy places. It is protected on the north by a bank, with a hedge interspersed with trees, and on the south by trees. A large willow-tree (*Salix alba*) on the south-west shades the sun's rays, but still there is ample sky light overhead, which I find so desirable for the growth of all ferns. . . .

"My Fern Glade has given me so much pleasure, that I strongly advise every one who has a waste piece of land near his garden to make a fern glen. It will be a pastime in the winter evenings to design it; the construction of it—the transforming of the ideal conception of the mind into a living reality—will afford much pleasure; many a country trip in the woods will be required to furnish it; and when furnished it will afford a spot for contemplation and enjoyment, in which the designer may fancy that the robins, warblers, and nightingales, which never fail to dwell there, are pouring forth their gratitude for the construction of such a delightful retreat.

"My Valley of Ferns is another spot in which I greatly delight. It has a stream through the centre, and it is well surrounded by trees. Here two or three varieties of male ferns and of polystichums attain their highest perfection. The magnificent *Struthiopteris* raises its graceful and delicate fronds in the early spring, and shows its finely-coloured foliage when dying down in the early autumn.

"In the heat of summer the beauty of a great mass of ferny foliage, such as this place affords, cannot be surpassed. The success of this valley of ferns appears to be due to the protection afforded from cold winds by surrounding trees, whilst the plants themselves luxuriate under light and sunshine, with free exposure to air without draught . . .

"At this moment I have nearly every British fern growing out of doors, but I could never succeed in cultivating the *Asplenium marinum* in that situation. This fern grows wild by the sea-coast as far north as Aberdeen; nevertheless I have never been able to grow one in any of my outdoor ferneries. It is a remarkable fact that the *Adiantum Capillus-Veneris* (Fig. 9) has never proved to be hardy with me, although I have it now growing well in the Fern cave. I have seen it along the Mediterranean coast beyond Mentone, but only in particular situations, such as on a bed of sandstone, which is permeable by water; in this situation the fronds were severely frosted in winter. I saw a plant growing at the top of the Cathedral at Genoa, at a time when all the fountains in the city were frozen. I noticed it again to be plentiful at Pompeii and at Herculaneum, and also in the ruins of Nero's Palace at Rome. But nowhere was the maidenhair seen in such perfection as in the ruined amphitheatre at Posilippo, near Naples. The underground rooms and passages formerly used by the gladiators, and for the working machinery of the amphitheatre (which is the most perfect of any now existing), forms a series of caves, through the walls of which moisture continually oozes, and here the maidenhair luxuriates in all its glory. Some of the fronds were eighteen or more inches in length, and the earthen walls were covered with sheets of this lovely fern, standing out at right angles from the wall or hanging down from the roof. I must confess that, when I beheld this great and glorious sight, I was more impressed with it than with the thought that I was present on a spot where dramas of blood were enacted centuries before. I speedily collected a number of plants, to the no small disgust of the *cicerone* who could not do the amphitheatre at his usual gallop, and who shrugged his shoulders at my utter want of taste in gathering useless weeds. Some of these plants now grow at my garden in the Fern cave. The *Adiantum* is said to luxuriate in the orange groves in Spain, in which country the fronds are used to make the syrup of capillaire, a pleasant beverage drunk mixed with water in hot weather."

Probably few are aware that in the clefts of that remarkable formation known as the "limestone pavement," in the west of Co. Clare, Ireland, the maidenhair fern may be gathered flourishing with a luxuriance of growth fully equal to that here described in Italy.

Mr. Smee's "My Garden" is, indeed, a book which ought to be in the hands of every one who is fortunate enough to possess a garden of his own; he is certain to find some things in it from which he may profit. The mode in which the work is got out—the paper, the printing, and the binding—leaves nothing to be desired. The style of the larger illustrations may be judged from the sample we have given; the smaller figures are in most

instances equally good, the botanical ones from the pencil of Mr. Worthington Smith, and they abound on almost every page. Some of them might certainly have been spared, as, for instance, the drawings of Mr. Smee's garden roller and water-pot, which do not appear to differ essentially from similar instruments which might be found in any other garden. But these are small defects, which scarcely depreciate from the value of the work in helping to promote among the inhabitants of our great cities a healthy love of country pursuits, and of the study of Nature herself.

A. W. B.

NOTES

SIR JOHN LUBBOCK, Bart., M.P., F.R.S., has been elected Vice-Chancellor of the University of London in the room of Sir Edward Ryan, who accepted the office for a year only on the death of the late Mr. Grote. We may congratulate ourselves that by this appointment the interests of Science will be well looked after in the future career of the metropolitan University.

DR. H. W. ACLAND, Regius Professor of Medicine, and Dr. G. Rolleston, Linacre Professor of Physiology, have been nominated to represent the University of Oxford on the Committee of Reference for the Medical Examining Board for England.

AT the examination for the degree of D.Sc. just concluded at the University of London, the following gentlemen passed to the satisfaction of the examiners:—In Branch VI.—Electricity, Alexander Muirhead; in Branch IX.—Animal Physiology, Henry Newell Martin, M.B.

THE following despatch from Dr. Kirk respecting Dr. Livingstone, dated Zanzibar, May 2, is published in the *Times of India*:—"Letters have been received from Unyanyembe, and Mr. Stanley is now within a few days of the coast on his return, having with him a large box full of correspondence and papers. Arabs state that Dr. Livingstone has visited Uvira, and found the River Rusiri flowing into the lake; but on this point we must await Dr. Livingstone's own report. He then returned to Ujiji, and was met by Mr. Stanley. Dr. Livingstone has gone to Unyanyembe, where he remains. He is in good health, and intends further explorations south after arrival of additional stores from the coast. Two of the Nassick boys who started some years ago with him are in his company, and he is said to be still using the sextant, and taking observations regularly. All his letters are in Mr. Stanley's care." Another despatch, published in the *Bombay Gazette*, dated Zanzibar, May 3, says:—"Dr. Livingstone has reached Unyanyembe. At Ujiji he was met by Mr. Stanley, who is expected daily at Zanzibar, having in his hands a large case of correspondence that will fully explain Dr. Livingstone's recent travels, embracing the north end of the Tanganyika Lake, and solving the Nile problem. Dr. Livingstone is said to remain still in the Unyamwazi country, and to intend further discoveries to the southward on the receipt from Zanzibar of additional supplies and stores. The Livingstone Relief Expedition is now on the African coast ready with all the necessaries for African travel, and Dr. Livingstone's son forms one of its members."

IT is with regret that we have to record the death, on the 27th ult., of Mr. Charles Hill, at his residence, Cotham Grove, Bristol. The deceased gentleman was in his 78th year, and for a long time had taken much interest in astronomical matters. Mr. Hill was in the possession of an excellent observatory, and his scientific instruments were of the first order.

AT the provincial meeting of the Horticultural Society, held at Birmingham last week, Prof. Thiselton Dyer read an address on the bearing of recent scientific investigations on horticulture.

IN his third and concluding lecture at the College of Surgeons, Prof. Humphry continued his exposition of the morphology and homology of the muscles of the limbs in man. Though arranged in accordance with the movements of the several joints of the limbs upon the flexor and extensor aspects, yet the extensor muscles not unfrequently incline on the sides of the joints, from the extensor to the flexor aspects, and so, irrespective of their nerve-supply, acquire a flexor action. This he believed to be the case with the biceps flexis cruris, which he has shown, from the anatomy of the Cryptobranch in the last number of the *Journal of Anatomy*, to be a derivative from the extensor mass in the thigh. Occasionally, also, as in the case of the *lumbricales*, flexor muscles acquire an extensor action. He spoke of the tendinous intersection in the semitendinosus as being the representative of a similar intersection in the Cryptobranch found at the junction of the caudal with the femoral muscle; and believed it to be present in man for the purpose of dividing the fibres of this muscle, which are of unusual length in consequence of the range of action required of them by the insertion of the tendon at a greater distance from the centre of motion at the knee than the other hamstrings. The ulnar origin of the pronator teres is a representative of the pronator intermedius of reptiles. It is found in the chimpanzee as well as in man, and serves to carry on pronation of the forearm in the flexed position of the elbow in which the remainder of the muscle is relaxed. In like manner the accessorius in the foot serves to maintain the flexion of the toes, while the flexor digitorum is relaxed by the bending of the ankle. This muscle has no representative in the upper limb of man, or in the fore limb of mammals, but it is well represented in the fore limb of Saurians. The great difference in the construction of the two limbs is caused by the pronation and supination in the fore arm and hand, and by the projection of the heel; and the representatives of the muscles, which in the upper limb affect the movements of pronation and of flexion of the fingers, are in the lower limbs, to a considerable extent, concentrated upon the knee. In instituting the comparison between a hand and foot, the Professor observed that it is necessary to eliminate from the consideration those features which ordinarily distinguish the one limb from the other; and this has not been done with sufficient care by some of those who have recently discussed the subject. We should first determine the points in which the hand of man differs from the terminal part of the ordinary fore limb of a mammal; and we may apply the term "hand" to the terminal part of either limb which presents a corresponding modification. This may take place in the hind limb, although the heel may project, and though a peroneus longus muscle, and a short flexor, and a short extensor of the digits may be present. These have been insisted on as the anatomical features of a foot as distinguished from a hand. But in reality they are rather the features of a hind limb as distinguished from a fore limb; and their presence is quite compatible with a modification of the hind limb corresponding with that modification of the fore limb which constitutes the hand of man. Judged in this way the terminal part of the hind limb of a gorilla or a chimpanzee has as much claim to be called a hand as has the terminal part of the fore limb in the same animals. Hence the term "quadrumanous" is, on anatomical ground, fairly applicable to these animals and their allies, as there is no sufficient reason to deny to man the prerogative of special subdivision of labour in the parts of his frame, and, consequently, of high organisation which is significantly implied by the term "bimanous." These lectures are in course of publication in full in the *British Medical Journal*.

THE concluding excursions of the Geologists' Association for the present season will be as follows:—Monday, July 8, excursion to Walton-on-the-Naze; director, Prof. Morris. Saturday, July 13, visit to the International Exhibition; director, Prof.

Tennant. Monday, July 22, and five following days, excursion to Ludlow and the Longmynds; directors, Prof. Morris, Mr. Robert Lightbody, and Rev. J. D La Touche. This excursion is intended to afford members an opportunity of studying Silurian and Cambrian Strata, and will be of great value to students of the Palæozoic Rocks. On Monday, after arrival at Ludlow, the party will examine the exposures of the Ludlow group of rocks in the immediate vicinity of the town. On Tuesday the objects of attraction will be the outcrop of the Upper Ludlow on the road to Wigmore, the Aymestry Limestone, and the Lower Ludlow. After passing Elton Hall, examine fine and Fossiliferous Section of the Lower Ludlow, at Evenhays (Vinal Ridge). Proceed then to Burrington (Wenlock Shale), Bank of the Teme (good section of Wenlock Shale), and Church Hill Quarry, Leintwardine, famed for Echinoderm remains. On Wednesday, leave Ludlow for Hayton's Bent, where the Old Red sandstone is exposed, and may be examined with advantage. On Thursday, proceed by Bishop's Castle Railway for the south end of the Longmynds, where the Wenlock Shales will be examined, and the physiography of the district formed by the Llandeilo Rocks observed. Walk back through the Valley of the Onney, observing on the way sections of Silurian Rocks from the Lower Caradoc to the Wenlock. On Friday, proceed by rail to Lydham Heath, thence to Shelve (Lower Llandeilo). Walk over the Stiperstone and Longmynd Ranges to Church Stretton, and examine junction of Cambrian and Silurians. On Saturday, from Craven Arms walk to Norton Camp, observing by the way Wenlock and Ludlow Sections, and at Norton inspect a good exposure of the "Bone Bed." Should time permit, proceed to Onibury, and inspect junction of Silurians and Devonians, and a fossiliferous section of Lower Ludlow Shale.

A NEW work on Electrostatics by Sir William Thomson will be published by Messrs. Macmillan and Co. early in August. It will consist chiefly of articles which originally appeared at different times during the last thirty years, in the *Cambridge Mathematical Journal*, the *Cambridge and Dublin Mathematical Journal*, Liouville's *Journal de Mathématiques*, the *Philosophical Magazine*, Nichol's Cyclopædia, the Reports of the British Association, the Proceedings of the Royal Societies of London and Edinburgh, of the Royal Institution of Great Britain, and of the Philosophical Societies of Manchester and Glasgow; and which will now be first collected and published together. The rest, constituting about a quarter of the whole, will be printed from manuscript, which, except a small part about twenty years old, entitled "Electromagnets," has been written for the present publication, to fill up roughly gaps in the collection.

THE two modes of photographic printing known as the Albert and Woodbury processes have both been employed by Prof. Agassiz in the illustration of his forthcoming "Revision of the Echini." Prof. Agassiz has kindly permitted us to see specimens of both modes of illustration. They are simply exquisite, portraying every marking on the surface of the shells with the accuracy of nature printing, and with the beauty of a lithograph. The practical working of these new modes of photographic printing must speedily work a complete revolution in the illustration of works on Natural History.

A VALUABLE report, prepared by Mr. R. D. Cutts, of the United States Coast Survey, upon commerce in the products of the sea, has just been published by the Senate, and is considered a valuable contribution to the statistics of the fisheries of America and of the rest of the world. In this the different marketable products are described in detail, and the relative rank which they occupy in commerce indicated. In addition to this, there is given the area, population, most important ports, and commercial tonnage of the principal nations of the world; the imports and exports of the products of the sea; showing the capacity of the markets and the countries supplied; and also the catch, consumption, and balance of trade, from official statistics. This Report was prepared in 1869 by request of the Secretary of State, and transmitted in February of that year, but the order to print was not made till receetly.

THE Report of the Government Cinchona Plantations at Ootacamund in India for 1870-71 states that the growth of the plants has been very satisfactory. The older shrubs have grown into trees 22ft. to 23ft. high, and 18in. to 21in. in girth. Of the *Cinchona succirubra* the finest samples reach a height of 30ft., with a girth of 3ft. Among the new species of plants lately introduced is the Pitayo bark, which appears hardy and well suited to the climate. During the year 51,353lbs. of fresh bark were supplied to Mr. Broughton, the Government quinologist, for the manufacture of amorphous quinine. From 1,000 eight-year-old plants of the *Cinchona succirubra*, as much as 2,560lbs. may be expected to be extracted this year. This average of more than 2½lbs. to each tree will yield at the present rate of 2*s*. 8*d*. to 3*s*. per lb., a clear profit of at least 2*s*. per lb.

PROF. LEIDY, at a meeting of the Philadelphia Academy of Secicnces, on February 6, exhibited specimens of corundum from Macon County, North Carolina, which, he said, were especially interesting, as they consisted of fragments of large crystals of gray corundum, containing in the interior dark blue sapphire, and coated on the exterior with bright red ruby. One pyramid of a large crystal from the same locality recently brought to that city weighs 300 pounds.

AT the meeting of the American Fish-Culturists' Association, held at Albany, it was voted to present to Congress a memorial for aid from Government in stocking the rivers of the United States with useful food fishes. Mr. George Page Shepherd, of New Jersey, was appointed to present the memorial, and had an opportunity not long since of expressing his views before the House Committee on Appropriations.

ACCORDING to Dr. Uhler, of Baltimore, the European cabbage butterfly (*Pontia Brassicæ*), the pest of the agriculturist, has reached Baltimore in its invasion of the United States. It has been known for some years more to the eastward, and has been slowly but surely creeping along, until it bids fair to involve the whole country in its ravages.

WE reprint the following interesting note from *Harper's Weekly*:—"As is well known, grouse, pheasants, ptarmigans, and some other gallinacea have a red patch or wattle above the eye, this being so conspicuous in some species as to resemble a piece of red flannel. This has been lately subjected to a careful analysis by Dr. Wurm, who ascertains that it contains a new organic colouring material, which he calls *Tetronerythrin*, or grouse red. It seems to lie in the deeper strata of the epidermis, like the colouring matter of the human skin, and to be partly dissolved in the deep layers of the cells, and partly to common with the colouring matter of the blood. The fact has been well known to bunters that if a white cloth be rubbed over this red process the colour will come off."

THE *New York Journal of Commerce* gives circulation to a story of an extraordinary fall of fish-bones (?) in Louisiana, covering the ground over a considerable area.

LATE Chilian papers announce the discovery of important mines of coal in that country, especially along the Gulf of Aranco, near the mouth of the Carampangue River. According to an official report, one of these veins is five feet thick, and is estimated to contain four million tons of coal.

THE SCIENTIFIC RELATIONS OF GERMANY, FRANCE, AND ENGLAND

THE following extracts from M. Berthelot's recent excellent article in the *Temps*, on the Relations which should exist between Germany and France, are taken from a recent number of the *Pharmaceutical Journal*:—

We know that modern civilisation depends upon three nations, which should at all times and at any cost remain united—namely, France, Germany, and England, each with its peculiar genius and its share in the historic development of the human race. From the seventeenth century each of these nations has taken an active and prominent part in the progress of science.

To speak first of physical and mathematical sciences. Though the initiative was due principally to a few men of other countries—Galileo, an Italian, and Copernicus, a Pole, being the founders of modern astronomy and mechanics—yet the development of these sciences was concentrated chiefly in France, Germany, and England. In France, Descartes discovered the methods of geometric analysis, which have proved more durable than his philosophical and cosmogonical theories. In Germany, Kepler invented the laws of planetary movement; and Leibnitz, who by education and the clearness of his conceptions was perhaps more French than German, laid down the rules of the differential calculus under a form in which they still exist amongst us. At the same time, England produced Newton, greater, perhaps, in the science of nature than either Descartes, Kepler, or Leibnitz; for Newton discovered both new methods of calculation and the laws of astronomy, and since his time we have scarcely done more than develop his ideas and doctrines in studying the movement of the stars.

This same concourse of the three great nations of modern times is seen also in the foundation of chemical science, which in the present day plays so important a part, whether it be in the theories relative to atoms and the constitution of matter, to the formation of stars and of the successive layers of the terrestrial globe, to the origin of life itself; or, on the other hand, in the applications of human industry, dealing with metals, colouring matters, remedies, agriculture, and manufactures.

Towards the end of the eighteenth, and at the commencement of the nineteenth centuries, chemistry was established upon a durable basis, after having floated during nearly two thousand years amongst mystical, obscure, and incoherent notions. It was a Frenchman, Lavoisier, who fixed these indecisive ideas, by the definite principle of the stability of matter, invariable in the nature and weight of its simple bodies. Perhaps, as has been asserted, Lavoisier did not discover any particular fact; but, according to Aristotle, principles and causes are things which are of more scientific importance, for by them we arrive at other knowledge. Now Lavoisier discovered the fundamental principle of chemistry; the science dates from him.

Is this saying that Lavoisier divined all, perceived all, traced for all time the plan of chemical science? Not at all; no more than that Newton alone founded astronomy. For this the inevitable concourse of the great nations was required. Whilst Lavoisier published his immortal researches, the English Priestley and Cavendish discovered the principal gases and the nature of water—inventions that were seized immediately by Lavoisier to support his theory. The Swedish Scheele brought also his precious contingent to the common work. Some years afterwards, an Englishman of genius, Humphry Davy, completed the edifice by the discovery of the alkaline metals, which he obtained by the application to chemical decompositions of the pile recently discovered by a great Italian, Volta.

Germany equally marked its place in the foundation of the new science. It was in the law of numbers that its work was principally characterised: Richter, Wenzel, and the great Berzelius (a Swede) established the law of chemical equivalents, that is to say, a law as general and as absolute in chemistry as the law of Newton in astronomy. It is remarkable that the part of the Germans in this discovery has been principally experimental and practical, contrary to the opinion generally received of German genius. On the contrary, the atomic theory, properly so-called, of a character more abstract and more litigious, is due to an Englishman, Dalton; whilst its demonstration by the physical study of the gases has been accomplished by a Frenchman, Gay-Lussac. This shows that the geniuses of the European races are not so different as has been asserted. Give them a common and equally high culture, and from each will proceed inventions equally original.

This conjunction of Germany, France, and England is to be seen in every great epoch in the history of modern science. The demonstration could be carried down to the present time, proving that neither of these three nations has degenerated from its past: the doctrine of substitutions, the theory of the ethers, that of the polyatomic alcohols, dissociation, the idea of organic ferments, the methods of synthesis of organic principles, have been principally established by French discoveries; the theory of the radicals and that of the polyatomic elements are rather to be attributed to German discoveries; whilst the electro-chemical theory and the method of double decompositions have been invented in England. Finally, the great doctrine of the equivalence of the natural forces, more particularly designated under the name of the mechanical theory of heat, was first discerned by a German, Mayer, and an Englishman, Joule. Developed afterwards by a German mathematician, it has been established in chemistry principally by the experiments of French, English, and Danish scientific men. But it would not be wise to dilate upon the science of the present day; we are too near to it, and are too much engaged in it, for any estimate to escape suspicion of partiality.

In looking back over this short sketch of the progress of the science with which I am best acquainted, I would not ignore the part of Italy, which in the past was so great (may it resume its importance in the future!), nor that of the United States, nor of Russia. But, I repeat, the initiative of the ideas and discoveries has rested for more two centuries in the bosom of three nations—English, French, and German. Their union and their reciprocal sympathy is indispensable, under the penalty of a general loss to civilisation.

INSTRUCTIONS FOR PREPARING BIRDS' EGGS *

I WISH to say a few words for the benefit of those engaged in collecting oölogical specimens.

Twenty years ago all eggs were blown with two holes—one at each end, and until within ten years most eggs have been emptied with two holes as above, or at the side. Very many of the eggs which I now receive in my exchanges are similarly prepared. At the present time no experienced collector ever makes but one hole to remove the contents of the egg, using a blowpipe in some form to accomplish this object. The following rules should invariably be followed:—

1. Prepare your eggs neat and clean. There is no excuse for having a dirty set of eggs where water, soap, and a tooth-brush can be found. Some eggs will not bear washing, as the shell is so calcareous that the characteristic markings will wash away. There are, however, but few of this class, and I believe this peculiarity is confined to the water-birds. You can see it in any of the species (Smithsonian Catalogue) from 615 to 628 inclusive, and also in the eggs of the Grebes and Flamingo, and some others. Having once seen it you will never mistake it for anything else.

2. Make but one hole, and that a small one in the middle of the egg; cover this hole, when the contents are removed, and the specimen is dry, with gold-beater skin or the paper number indicating the bird. Use an egg drill or a pointed wire of four or six sides to make the opening.

3. If the blowpipe does not readily remove the contents of the egg, inject water and shake the specimen thoroughly, then blow again, and repeat the operation until every particle of the egg is removed.

4. If the embryo is too far advanced to remove through a moderate sized hole, blow out what you can of the liquid part and fill the egg with water, wipe it dry and put it away in a covered box in some warm place, and every twenty-four or forty-eight hours shake it well and remove what you can, and then refill with water. Repeat this operation several times, and after a few days the contents will become sufficiently decomposed to take away.

5. After removing the contents of any egg, cleanse the shell thoroughly. Fill it with clean water and shake vigorously, blow out the contents and repeat the operation until the specimen is perfectly clean. This is particularly desirable in white eggs, as black spots will show through the shell after a time if the least particle of the egg or blood stains remains inside.

* By William Wood, M.D. Reprinted from the *American Naturalist*.

6. Save all your eggs in sets—that is, keep all the eggs each bird lays by themselves. This is the only way to form a correct knowledge of the eggs of any species, as a single egg, particularly of the blotched ones, frequently gives a very erroneous idea of the general markings—a very unsatisfactory representative of a set. For instance, in my collection are four eggs of the *Buteo lineatus*, found in the same nest, two of which are pure white and two blotched. It is not very uncommon to find great variations in markings in the same species and in the same nest.

7. Keep a memorandum of the place and date of collecting each set of eggs.

8. Use some kind of blowpipe in preparing your eggs for the cabinet. The common blowpipe, with the addition of a fine pointed tip, will answer; yet it is a severe tax on the lungs and brain if you have many eggs to blow. I have many a time been dizzy and almost blind from overtaxing my lungs in this operation. Within a few years Mr. E. W. Ellsworth, of East Windsor Hill, Conn., has invented a blowpipe which is operated by the thumb and finger, which works very perfectly and expeditiously. I would not be without it on any account. After using it for a time, and then letting it remain unused until the leather packing becomes dry, the instrument does not work satisfactorily to those unaccustomed to it. The remedy is simple. Take off the blowpipe and work the instrument submerged in a bowl of warm soap suds, when the leather packing becomes pliable and works as well as new. I have used the same instrument for years, and it works to-day as well as when new, by following the above directions. The printed directions which accompany each instrument are intended to be a sufficient guide in case repairs are needed, and the maker can be referred to for any further information required.

SCIENTIFIC SERIALS

THE *Geological Magazine* for May (No. 95) opens with an important article (illustrated with a plate) on some coniferous remains from the Lithographic Stone of Solenhofen by Mr. Dyer, in continuation of a former paper on the same subject. This paper includes the description of a new species of *Pinites* (*P. solenhofenensis*), a revision of the genus *Athrotaxites*, with descriptions of two new species (*A. longirameus* and *A. ? laxus*), and a notice of a new genus, *Condylites*, probably belonging to the Cupressine group, and including a single new species, *C. squamatus*.—MM. H. B. Woodward and J. H. Blake communicate a valuable paper on the relations of the Rhætic beds to the Lower Lias and Keuper formations in Somersetshire, in which they cite additional evidence and arguments in support of the view that the Rhætic beds constitute true passage-beds between the Keuper and Liassic series.—Principal Dawson gives us the results of a new examination of the geological structure of Prince Edward's Island in the Gulf of St. Lawrence; and Mr. Alfred Bell a paper on the succession of the Crags, the latter containing a criticism of Mr. Prestwich's recently-published memoirs on the same subject.—Mr. James Geikie communicates a sixth paper on changes of climate during the glacial epoch, and the number concludes with an interesting lecture on meteorites by Mr. David Forbes.

THE *Monthly Microscopical Journal*, No. 42, for June, completing the seventh volume, contains communications on "An Improved Reflex Illuminator for the Highest Powers of the Microscope," by W. H. Wenham; on "A Silvered Prism for the Successive Polarisation of Light," by J. W. Stephenson; "Structure of Battledore Scales," by J. Anthony, M.D., detailing fresh investigations by a new method of of illumination, the results of which confirmed those of a previous communication; "Beale's Nerve Researches: the Reply of Dr. Beale to Dr. Klein;" "On Bog-Mosses," by R. Braithwaite, M.D., part iv., devoted to *Sphagnum tenellum* Ehrh., and its varieties. This is the *S. molluscum* of Wilson's "Bryologia;" "Crystallisation of Metals by Electricity," by Philip Braham; "On the Means of Distinguishing the Fibres of New Zealand Flax from those of Manilla or Sizal, by the Microscope," by Captain Hutton. The average length and diameter of the ultimate fibres are held to be distinctive, as well as some other less important points, in the discrimination of these fibres. The residue of this number is occupied, as usual, with brief notices of new books, notes on microscopical subjects, and the proceedings of microscopical societies.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, June 19.—Prof. Ramsay, V.P., in the chair.—The following communications were read:—1. "On *Trochocyathus anglicus*, a new species of Madreporaria from the Red Crag," by Mr. P. Martin Duncan, M.B., F.R.S. The author described a coral, of which a single specimen had been found in the Red Crag, in the grounds of Great Bealings Rectory, Norfolk. He stated that it belonged to the genus *Trochocyathus*, and was distinguished from the other species of that genus by its dense epitheca, its small and prominent columella, and its inverted calicular margin. He proposed to name it *Trochocyathus anglicus*, and stated that its nearest alliance is with the Australian Upper Tertiary form described by him under the name of *T. meridionalis*. Mr. Prestwich inquired whether the fossil bore any resemblance to any of the French Eocene forms, and whether there was any possibility of its being derivative. Prof. Duncan replied that the specimen was but little worn, and was therefore probably not *remanié*, though this point was not absolutely certain. 2. "On the Discovery of Palæolithic Implements in association with *Elephas primigenius* in the High-terrace Gravels at Acton and Ealing," by Colonel A. Lane Fox, F.G.S. The gravels in the neighbourhood of Acton have been divided by Mr. Prestwich into two principal groups—viz., the high-level gravels on the hills above the valley, and the valley-gravels on the sides and bottom of the valley itself. The valley-gravels have been again divided by Mr. Whitaker into three terraces—viz., a high terrace, between 50ft. and 100ft. above the Ordnance datum, a mid terrace, between 20ft. and 40ft. high, and a low terrace, at an average height of 10ft., occupying the low ground in the bends of the river. On both sides of the river the high terrace is separated from the mid terrace by a strip of the London Clay, which is laid bare at an average level of 50ft. The London Clay is also laid bare on the sides of the tributary streams running into the valley on both sides of the river, thus dividing the high-terrace gravel into patches. The mid terrace is continuous, and follows the sinuosities of the valley on both sides up to the strip of London Clay. The author accounts for this distribution of the gravels by supposing that a large body of water must at one time have stood at the 50-feet level, and the denudation of the high terrace have been caused by the waves beating on the sides of the valley, and by drainage into this body of water. The mid terrace he conceives may have been caused in part by accumulations beneath this body of water. The position of the high-terrace gravel at Acton corresponded so closely to that of the implement-bearing gravels of the Somme and the Ouse that the author was led to examine carefully the excavations made in it for the construction of houses. He discovered a number of implements of the drift-type, together with flakes and cores, and a few roughly-formed scrapers; all these were found in close contact with the London Clay, and beneath the gravel. Fragments of fern (*Osmunda regalis*) and of wood (*Pinus sylvestris*) were also found with the implements at the same level. Two implements were found at Ealing Dean, two miles westward, on nearly the same level as those at Acton—viz., 90ft.; and these also came from the bottom of the gravel. Another implement was found south of the river at Battersea Rise, in the same position above the strip of London Clay as at Acton, and at about 60ft. above the Ordnance datum. The implements are of the pointed and oval types. The only animal remains discovered in the high terrace consisted of a tooth of *Elephas primigenius* in the Acton gravel. The position of this the author believes to be reliable, although he did not discover it himself *in situ*. In the mid-terrace gravel a number of pits were examined between Shepherd's Bush and Hammersmith, and in the neighbourhood of Turnham Green, which resulted in the discovery, at the latter place, of a large quantity of animal remains (noticed by Mr. Busk in the following paper), all of which, like the implements of the high terrace, were at the bottom of the gravel; but no evidence of human workmanship was found in the mid terrace. All these were found together, in the same seam of gravel, 12ft. beneath the surface, and all appeared to have been deposited at the same time. The surface was here 25ft. above the Ordnance datum, and consequently about 50ft. lower than the implements of the high terrace, 1½ mile to the north. The section across the valley, taken through the two places, here shows the strip of the London Clay intervening between the two terraces. The chief points of interest which the author submitted to the judgment of geologists consisted in the presence of drift imple-

ments in the high terrace, their absence in the mid terrace, and reappearance in the existing bed of the Thames; the great rarity or absence of animal remains in the high terrace, and their abundance in the mid terrace, and the occurrence of both implements and animal remains at the bottom of the gravel in both terraces. The writer concluded by adducing proofs of the great antiquity of the present river-bed, which it was shown must have run in its present meandering course in the bottom of the valley for at least 2,000 years. 3. "On the Animal Remains found by Col. Lane Fox in the High and Low-level Gravels at Acton and Turnham Green," by Mr. George Busk, F.R.S. The author described the mammalian bones referred to in the preceding paper. The remains from the high-level gravels at Acton belong to the genera *Bos*, *Ovis*, *Equus*, and *Elephas*? The greater part belong to the first-named genus, and are probably modern, as are also those of *Ovis*. The remains of *Equus* may be of greater antiquity. The other bones found may belong either to Elephant, Rhinoceros, or Hippopotamus; they include a large portion of an Elephant's molar, and are much rolled. The remains from the mid-level gravel at Turnham Green generally present the characters of great antiquity. They include bones of *Rhinoceros hemitœchus*, *Equus caballus*, *Hippopotamus major* (one of them the left frontal of a very young animal almost unworn), *Bos* (probably *B. primigenius*, and some perhaps *Bison priscus*), *Cervus* (*C. clactonensis*, Falc. = *C. Browni* Dawk., *C. elaphus*, and *C. tarandus*), *Ursus ferox priscus*, and *Elephas primigenius*. Mr. Prestwich complimented the author on the exactness and completeness of his description of the classical district which he had investigated, in which mammalian bones had been found and described by Mr. Trimmer so early as 1815. In that case Hippopotamus remains, very fresh and unworn, had also been discovered. Prof. Morris had also described a deposit near Brentford in which numerous remains of Reindeer were present, showing how variable was the distribution of mammalian remains even in a limited area, and how unsafe it was to base theories upon merely negative evidence. It was to be hoped that other investigators would extend similar discoveries to other parts of the valley of the Thames. Mr. Godwin-Austen did not think that the presence of the young Hippopotamus was absolutely conclusive of its having been born in this country. With regard to the presence of remains of Reindeer and Hippopotamus in the same beds, not only might there have been an overlapping of fauna such as has been pointed out by Sir Charles Lyell, but there also might be an intermingling of the included remains from two beds of different ages. He was not altogether satisfied with the evidence as to the coexistence of man with *Elephas primigenius*, nor as to the artificial character of some of the presumed implements. He did not attach any great importance to the merely fragmentary bones. Mr. Evans maintained that the implements exhibited were of necessity artificial, and commented on the nature of the evidence as to the coexistence of man with the Pleistocene fauna. Under any circumstances the gravels containing the implements could only have been deposited at a time when the Thames valley had not been excavated to anything like its present depth; and they were therefore of great antiquity. There was, moreover, a notable absence in them of a number of the animals usually found associated with Neolithic implements; and if man had not subsisted on the animals the remains of which were found associated with his handiworks in the gravels, it was a question on what food he had had to depend. The absence of implements in the low-level gravels seemed to him significant of a diminution in the number of the human beings who frequented the banks of the river. Mr. Carruthers said that as the rhizome, whether it was that of *Aspidium* or *Osmunda*, was an aërial, and not a subterranean rhizome, it must have been carried to its present position; and it consequently indicated, as Col. Lane Fo ' ad pointed out, the direction of the stream. Mr. Flower regarded Col. Lane Fox's memoir as of great interest, as affording an additional instance of that perfect similarity of these deposits, whether in France or England, which in places so wide apart might reasonably be taken to indicate a common origin. It was indeed generally assumed that these deposits were brought down by rivers; but this, according to his view, was by no means certain. Col. Lane Fox had described the valley as 4½ miles wide; but there was at Croydon, 12 miles distant, a deposit of gravel capped with loess, containing elephant remains, and exactly resembling the Thames valley-gravels, and communicating with them. This evidently formed part of the Thames valley system, whatever that system might be taken to be; and if so, he thought it incredible that the loess should have been distributed by river-action over an area 12 or 15 miles in width. In conclusion, he was quite content to adhere to the opinion held by the French geologists, and formerly by several of our own most able writers, that the distribution of these superficial drifts was in the first instance diluvial rather than fluvial. Col. A. Lane Fox, in reply, pointed out the artificial character of the implements, and the manner in which the mammalian remains occurred. He thought that the lower terrace of gravel might have been formed at the bottom of a lake. Mr. Busk, in proof of the animal remains not having been brought from a distance, showed that the remains of the same animal were found in close proximity to each other. Prof. Ramsay made some remarks on the undoubtedly artificial character of the implements, and on their position at the base of the gravels. The origin of the Thames valley he had already maintained to be of Postmiocene age; and though there was at present no evidence of man's existence at that time, it was still possible. Of the extreme antiquity of the human race there could, however, be no doubt. 4. "On the Evidence for the Ice-sheet in North Lancashire and adjoining parts of Yorkshire and Westmoreland," by R. H. Tiddeman. The country of which the earlier glacial phenomena were described in this paper lies between the Lake-district on the north and the plains of South Lancashire and Cheshire on the south, and extends from the great watershed of England to the Irish Sea. On the west is a seaside plain rising to levels of less than 200 feet. On the north-east is a portion of the Pennine Chain, comprising Ingleborough, Pennigent, and other Fells, rising to heights of from 2,000 to 2,400 feet. Between these, from north to south, we pass over (1) a range of moorlands from 1,000 to 1,500 feet high, called the Rossendale Anticlinal, which forms the watershed between the basins of the Mersey and the Ribble; (2), the valley of the Burnley and Blackburn Coal-field, which drains north through gorges in (3) the Pendle chain of hills into (4) the broad valley of the Ribble; (5), a group of Fells rising to a general level of 1,800 feet, between the valleys of the Ribble and the Lune, called, for the purpose of this paper, "The Central Fells;" (6), north of this the valley of the Lune and the estuary of the Kent. The main direction of all these features between the seaside plain and the Pennine Chain, is from north-east to south-west. The paper was illustrated by a map of the district on the scale of 1 inch to a mile, coloured to represent elevations, the level contours having been reduced from the 6-inch scale. Upon this all the ice-scratches found on the solid rocks were inserted. A diagram illustrating the proportional number of scratches in different directions showed that 20 per cent. of them were due south, although the general direction of the valleys was to the south-west. An instance was mentioned of a ridge of 1,400 feet in height, which had scratches at the top running directly across it to the south, although no land of equal height occurred north of it within a distance of seven miles. A similar instance was shown to exist on the ridge north-east of Pendle Hill. A *roche moutonnée* in the gorge of the Calder at Whalley was shown to have been formed by ice working from the north, although the river drains from the south. Other systems of scratches were mentioned in detail. All these tended to show that, though the general slope and drainage of the district is to the south-west, the movement of the ice at the period of maximum cold was to the S. or S.S.E., or nearly parallel to the watershed. The author goes on to describe certain disturbances at the surface of the rocks, which are dipping at high angles to the south, they having been overturned by some force coming from the north. Such surface-disturbances are not found on rocks dipping to the north; and this fact may be explained by an illustration: in one case the brushing was with the nap, in the other against it. In was shown that these phenomena could not be attributed to any other agent but a great ice-sheet pushing on from its northern gathering grounds, recruited by the greater elevations on its course, but overriding the lesser, grinding down and smoothing by its friction rocks presenting but a gentle incline, tearing up and turning over the basset edges confronting its approach. The author next described the arrangement of the Till as to colour and material, and endeavoured to show that all the facts which he has observed are in favour of the existence of an ice-sheet travelling south in this district. Mr. Cumming's observations in the Isle of Man were considered to confirm these views. He describes the general glaciation of the island as being from the E.N.E. or Lake-country, and describes many large blocks of granite which had been carried from their parent rock up the high hill of South Barruh and down on the other side. This was referred by Mr. Cumming at the time to a great "wave of

translation ;" but the facts are quite easily explained by an ice-sheet. Other observations of Mr. Cumming upon the drifts of the Isle of Man were taken by the author as confirmatory of his views. Mr. Morton's observations on the glaciation of the Mersey basin were touched upon ; and it was suggested that the glaciation of that district was produced by an ice-sheet, not coming from the south-east, as Mr. Morton holds, but working to the south-east from the Lake-country, and across a part of what is now the Irish Sea. Prof. Ramsay's observations on the glaciation of Anglesey being to the S.S.W. instead of from the Snowdon group, as might be expected, were considered by the author to be confirmatory of his views of a great ice-sheet having filled what is now the Irish Sea, and emptied itself by St. George's Channel on the one hand, and by the Cheshire plain on the other, as well as by some of the passes in the Pennine Chain.—5. "On the Mammalia of the Drift of Paris and its Outskirts." By Prof. Albert Gaudry, F.C.G.S. In this paper the author briefly indicated those mammals the remains of which have been discovered in the Pleistocene or Quaternary deposits of Paris and its vicinity. His list includes flint implements as evidences of the existence of man, and bones of the following species :—*Canis lupus*, *Hyæna crocuta* (*spelæa*), *Felis leo* (*spelæa*), *Castor trogontherium* and *fiber*, *Elephas primigenius* and *antiquus*, *Hippopotamus amphibius*, *Rhinoceros tichorhinus* (a Rhinoceros of doubtful species), *Sus scrofa*, *Equus asinus* and *caballus*, *Bos primigenius*, *taurus* (?), and *indicus* (?), *Bison priscus* and *europæus*, and *Cervus tarandus*, *Belgrandi*, *megaceros*, *canadensis* (?), *elaphus*, and a small species.

Zoological Society, June 18.—Mr. John Gould, F.R.S., vice-president, in the chair.—The Secretary read a report on the additions that had been made to the Society's Menagerie during the month of May, 1872. The most noticeable of these were two Argus Pheasants (*Argus giganteus*), presented to the Society by Mr. J. G. Fanshawe.—Mr. P. L. Sclater exhibited a pair of Ceylonese birds sent to him for determination by Mr. W. Vincent Legge. These birds Mr. Sclater considered to belong to a new species of the genus *Prionochilus*, which he proposed to call *P. vincens*, after one of the names of its discoverer.—Mr. Edwin Ward exhibited the horns of a Barasinga Deer (*Cervus duvaucellii*) with twenty points, and a very handsome and peculiarly grown specimen of the Gaur or Indian Bison, from Central India. —Mr. St. George Mivart read a paper "On the Axial Skeleton of the Ostrich" (*Struthio camelus*).—Dr. J. Murie read a paper "On the Cranial Appendages and Wattles of the Horned Tragopan" (*Ceriornis satyra*). After alluding to the phenomena of display during courtship, he went on to show that rudimentary horns are found in the female. In the male the pseudo-horns are composed of firm fibro-elastic substance, and are not due to vascular erection. The wattle, on the contrary, is a true erectile vascular organ.—A communication was read from Prof. H. H. Giglioli, containing an account of the Cetacea observed during the voyage round the world of the *Magenta* in the years 1865-68. In this were contained descriptions of several new or little known species, and of a new genus and species of Fin-backed Whale, proposed to be called *Amphiptera pacifica*.—Dr. J. Murie continued the series of his observations on the Macaques, commenced at the last meeting. The species selected for special notice were *M. arctoides* of Is. Geoff., which he showed to be identical with *M. brunneus* of Anderson :—The Formosan or Round-faced Monkey (*M. cyclopis*), and the Japanese Monkey (*M. speciosus*). Points in the anatomy and skeleton of each of these species were described.—A communication was read from Dr. J. E. Gray, containing the description of the younger skull of Steller's Sea Bear (*Eumetopias stelleri*).—A communication was read from the Rev. O. P. Cambridge, giving descriptions of twenty-four new species of Spiders of the genus *Erigone*.—A second communication from Dr. J. E. Gray, F.R.S., contained additional notes on new corals from the Southern and Antarctic Seas.—A further communication from Dr. Gray contained additional notes on *Arctocephalus cinereus*, and on *Gypsophoca*, from the coast of New Zealand.—Mr. A. H. Garrod read a description of the tongue of *Nestor hypopolius*, which showed that *Nestor* does not belong to the Trichoglossine group of Psittacidæ.

Mathematical Society, June 13.—Mr. W. Spottiswoode, Treas. R.S., president, in the chair. Prof. Cayley, vice-president, gave an account of his paper, "On the surfaces divisible into squares by their curves of curvature." Sir W. Thomson, Mr. Merrifield, and Prof. Clifford, asked for information on one or two points in the communication.—Mr. S. Roberts, vice-president, gave some details of his paper, "Prof. Cremona's transformation between two planes and tables relating thereto."—Reference was made to a paper by Prof. Cayley. "On the rational transformation between two spaces" (Proceedings Lond. Math. Society, vol. iii. pp. 127, &c.).—Dr. Hirst briefly sketched out a few results arrived at in his communication, entitled "A manifold correspondence of two planes." Sir W. Thomson explained the object of his short paper "On the simultaneous reduction of two prodynamical quadratics to sums of squares." He referred to papers by Prof. Cayley (Camb. and Dub. Math. Jour., Feb. 1869, and Quarterly Math. Jour. 1858), and to Conaby's problem "Sur l'équation à l'aide de laquelle on détermine les inégalités séculaires des planètes," treated of in vol. iv. of that writer's "Exercises." The Hon. J. W. Strutt referred the author to a memoir bearing on the subject of his paper.

Anthropological Institute, June 17.—Sir John Lubbock, Bart., president, in the chair. —Mr. A. W. Franks exhibited and described photographs of the tattooed man from Birmah—The following papers were read : "On the Hill Tribes of North Aracan," by Mr. St. Andrew St. John ; "The Ainos of Yeso," by Commander H. C. St. John, R.N. (communicated by the Admiralty) ; "Indian Picture Writing in British Guiana," by Mr. Chas. B. Brown ; "Report on Australian Languages and Traditions," by the Rev. W. Ridley, M.A. (communicated by the Colonial Office) ; "Report of the Anthropological Section of the Arctic Exploration Committee."

Linnean Society, June 20.—Mr. G. Bentham, president, in the chair.—Mr. A. W. Bennett communicated a short note on the mode of fertilisation in *Impatiens parviflora*. On the structural peculiarities of the Bell-bird (*Chasmorhyncus*), by Dr. Murie.

Geologists' Association, June 7.—Rev. J. Wiltshire, president, in the chair.—"On the Classification of the Cambrian and Silurian Rocks," by Henry Hicks. The author, after mentioning the groups now known to comprise the Cambrian and Silurian rocks, as exhibited in the British Isles, and the usual mode, hitherto, of dividing and subdividing these formations, stated that it was impossible in a science so progressive as geology, where new discoveries were continually being made, to accept at present any of these arrangements, which for the most part had been made some twenty or thirty years ago, unless with considerable modifications. The classification approved by the author has already been, to a great extent, adopted by Sir Charles Lyell in his "Students' Manual," and by the late Mr. Salter, and the author in papers to the British Association ; and is based on the most recent palæontological and stratigraphical evidence. In a table exhibited for the purpose of illustrating these facts, the classification of Prof. Sedgwick, and of Sir R. Murchison, were placed side by side along with the one proposed. The columns in the table showed (1) the lithological characters of the beds comprising each group ; (2) the thickness of the strata ; (3) the organic remains contained in each group ; (4) the number of genera and species which are known to reach from one group into another ; (5) the order of the appearance of animal life upon the globe, and (6) the localities where the several groups are best seen in England. By means of the evidence set forth in these columns, the author was enabled to show the most natural divisions and subdivisions, so far as recent researches are capable of explaining them. The following are the chief divisions accepted as being the most satisfactory at present :—The *Lower Cambrian* to include the Longmynd (Harlech grits and Llanberris slates, and the rocks at Bay Head, &c.) and the Menevian groups, which were shown to be intimately connected palæontologically, and to be entirely distinct in their faunas from the overlying rocks. The *Upper Cambrian* to include the Lingula flags (lower, middle, and upper, called also Maenturog, Festiniog, and Dolgelly or Malvern) and the Tremadoc groups. These were also shown to be connected closely by some of the genera, especially by Olenus, Conocoryphe, and Dikelocephalus. The *Lower Silurian* to comprise the Arenig (Lower and Upper, the former a series only recently known through the researches of the author, and forming a connecting link between the Tremadocs and the true Arenig rocks), the Llandeilo (Upper and Lower, the former being black shales or slates, and the latter calcareous), and the Bala or Caradoc groups. The *Upper Silurian* to consist of the Llandovery (Upper and Lower), the Wenlock and the Ludlow groups. The whole of the Llandovery group was placed in the Upper Silurian in accordance with the evidence cited by Prof. Ramsay in his memoir on North Wales, along with the facts explained by the table, and which went to prove that when it was to be separated entirely

from the other groups, as a Middle Silurian division, this was the most natural and proper position.—"On the Silurian Rocks of the English Lake District," by Prof. Alleyne Nicholson. In this paper the author classified the Silurian rocks of the English Lake District as follows, commencing with the lowest:—(1) The Skiddaw Slates, (2) the Borrowdale Series, or Green Slates and Porphyries, (3) the Coniston Limestone and associated shales, (4) the Graptolitic Mudstones, (5) the Coniston Flags, (6) the Coniston Grits, (7) the Ludlow Rocks. Each of these members of the series was described lithologically and palæontologically, and its geological position discussed, not only with reference to the other beds of the district, but also to the Silurians of Wales and North America.

Society of Biblical Archæology, June 4.—Dr. Birch, F.R.S., president, in the chair. "On a Religious and Political Revolution which took place in Egypt prior to the reign of Rameses III., having a probable connection with the rise of the Jewish religion. From the text of the Harris Papyrus," by Dr. August Eisenlohr. This magnificent Papyrus contains an account of the reign of Rameses III. and the events preceding his accession to the throne. Among these he finds a most marvellous account of a politico-theological revolution made by a Syrian hero, who, after a period of general disorder, made himself chief of the whole country, and abolished the existing religion and the sacrifices then in use. The father of Rameses III., King Seti-nekht, suppressed this revolution and restored the country to its former religious institutions. The striking resemblance of this story with the narrative of the return of the Hykshos, which was extracted by Josephus from Manetho's work, and was held by nearly all authorities to be connected with the establishment of the Jewish religion is very remarkable. Dr. Eisenlohr considered these passages in the Harris Papyrus as representing the Egyptian view of this and other great events which were the immediate cause of the Exodus, in which case the Papyrus would constitute the first Old Egyptian document hitherto discovered to bear upon the subjects treated of in the Book of Exodus. And it is therefore an additional gratification to learn that the Trustees of the British Museum have recommended to the Treasury the purchase of this invaluable document.—"Observations on the Dimensions of the Great Pyramid and the Royal Coffer," by Mr. Solomon M. Drach.—"The XXXVII. Aamu in the Tomb of Chnum-Hotep, at Beni-Hassan, identified with the family of Israel," by the Rev. Daniel H. Haigh. The learned author maintained that the said group, representing 37 Aamu or Mestemmu from the land of Shu, depicted no other than the patriarch Jacob and the thirty-six legitimate members of his family (the offspring of his wives Leah and Rachel), who entered Egypt at Joseph's invitation; the concubines and their children holding a decidedly inferior rank, and regarded as slaves and slave-born, not being counted, reducing the legitimate family of Jacob to that number. Shu he supposed to be the "East;" Mestemmu he compared with Beto-Mestham (Judith iv. 6), in the territory of Dothan, conquered by Jacob (Gen. xlviii, 22). In a supplement to this paper, Mr. Haigh described a Babylonian cylinder brought from Hidah, engraved by Mr. Layard in his "Travels," and translated the cuneiform inscription as representing Terah and his children, Abraham, &c. The names Iscah and Milcah (Queen) he considered might be one name in duplicate, the result of a marginal gloss (one sign in the cuneiform writing representing the sounds *is* and *mil*).

GLASGOW

Geological Society, May 2.—Mr. James Thomson read some notes "On an Undescribed *Platycrinus* from the Mountain Limestone of Fifeshire," which he had found in a quarry to the west of Kirkcaldy. It differs in several respects from M'Coy's *Platycrinus punctatus*. The plates of the test of that author's form are punctate, while those of the form exhibited are smooth and destitute of surface ornamentation. It also differs in the form of the plates.—Mr. Thomson also laid before the Society a curious shell, which he discovered on the same occasion. It was of somewhat large dimensions, being 10 in. long, by $7\frac{1}{2}$ in. in width at the broadest part. At first sight it seemed to be a variety of Nautilus, but he could not find any trace of the septa which characterise that important group of Cephalopoda. He was, however, disposed to view it as belonging to that group, but one which, so far as he was aware, had not been described in any work on Palæontology.—Mr. David Robertson read the following papers:—1. "On the Clay Beds at Kilchattan in Bute." Mr. Robertson gave an enumeration of 86 species which had been obtained from the locality, including 40 species of Mollusca, 16 of Ostracoda, 18 of Forminifera, and 12 of other orders. The prevailing shells of the deposit are *Tellina calcarea*, *Axinus flexuosus*, *Scobicularia prismatica*, *Cyprina islandica*, *Mya truncata*, and *Utriculus obtusus*. 2. "On a Fossiliferous Clay Deposit near Campbeltown." The chief interest of this section is that, contrary to the usual position of the boulder clay in the West of Scotland, here it overlies shell-bearing clay. The latter is dark grey in colour, and contrasts strongly with the overlying boulder clay, which is of a full reddish brown. The shell-bearing clay, as exposed in the bed of a little burn or streamlet in Tangy Glen, about six miles from Campbeltown, is seen standing up in the boulder clay like a little knoll, and has doubtless been brought to that form by abrasion. It can be traced for a distance of 60 or 70 yards; its exact depth could not be ascertained, but as the rock is seen at a short distance on either hand, it is probably not more than a few feet deeper than what is exposed. The boulder clay overlies it to a height of 50 or 60 feet. The latter consists of 50 per cent. of fine mud and 50 per cent. of sand and gravel, while the shell-bearing clay gives 80 per cent. of fine mud and only 20 of sand and gravel. The fossils are but thinly met with in this deposit—molluscs in particular are comparatively rare, the few found being chiefly *Leda pygmæa*, with an occasional *Leda pernula* and a few fragments of other species. Ostracoda and Foraminifera are better represented, 18 species of the former and 26 of the latter having been obtained. A remarkable feature of the Ostracoda in this deposit is that they have much in common with those found in the clays on the east coast of Scotland, which have been held to represent more strongly Arctic types than those generally found in the West. Amongst these are *Cytheropteron Montrosiense*, *Cytheropteron vespertilio*, and *Cytheropteron Sorbyana*. None of these have hitherto been met with in the clays of the West of Scotland, with the exception of one specimen of *C. Montrosiense*, which had been found in the excavations for Messrs. Randolph and Elder's new dock near Govan. This specimen was found at a depth of 18 feet in a lower bed of clay dipping away from the river. An upper bed, which dipped to the river, contained only more recent forms common to our raised beaches and present seas. He might add that *C. vespertilio* and *C. Sorbyana* are common species in the clays of Norway. The chairman observed that this additional discovery of Arctic marine shells below the lower boulder clay of the West of Scotland was a further confirmation of the interesting fact that an Arctic or northern fauna had spread over certain tracts of the existing sea bottom before the lower Till of the country was deposited.

PHILADELPHIA

Academy of Natural Sciences, Oct. 17, 1871.—The president, Dr. Ruschenberger, in the chair. "Remarks on Fossils from Oregon."—Prof. Leidy directed attention to some fossils, part of a collection from Oregon, submitted to his examination by the Rev. Thomas Condon, and indicated in the "Proceedings" of Oct. 18, 1870. One of the fossils, a brain cast, or rather a cast of the interior of the cranium of a large mammal, has about the same form and size as that of the horse. The cerebral hemispheres are nearly as much convoluted as in the latter, and measure about $4\frac{1}{2}$ inches in length and breadth. It may pertain to a large tapiroid animal, though I suspect it belonged to an oreodont. A large atlas, perhaps belonging to the same animal as the former specimen, measures 5 inches in breadth between the outer prominent borders of the articular concavities for the occipital condyles, and it is about $4\frac{1}{4}$ inches from the neural tubercle to the hypapophysis. It differs in several important points from the atlas of the rhinoceros, horse, ox, &c., and the want of sufficient means of comparison prevents a determination of its near relationship. Another fossil, labelled "Alkali Flats," consists of the greater part of the crown, apparently of a last upper premolar, or perhaps of a transverse pair of lobes of a true molar, of an animal as large as that to which the preceding specimens belonged. The tooth approaches in character the corresponding portion in the oreodonts, but differs in the proportionately less degree of development of the inner lobe of the crown as compared with the outer one, and in the greater degree of development of the inner basal ridge. The crown measures $1\frac{1}{3}$ inches in transverse diameter. These fossils appear to indicate an unknown pachyderm, which may be designated by the name of *Hadrohyus supremus*. Among the Oregon fossils there are a number of imperfect remains, of which it was

formerly remarked they indicated at least two species of rhinoceros. One of these was thought to be the same as the *R. occidentalis*; the other was suspected to be the same as the Californian species, *R. hesperius*. Some additional specimens indicate the second species to have been intermediate in size to that last named and the *R. crassus* of the Niobrara river. One of the specimens from Bridge Creek, consisting of a mutilated upper jaw fragment, with portions of the fangs of the true molars, shows these to have occupied the space of about 5 inches. An isolated tooth from Alkali Flat, apparently a last upper premolar, probably belongs to the same animal. From the outer part of its crown three folds project into the bottom of the median valley. The tooth measures 1 inch and 10 lines wide. The species may be named *Rhinoceros pacificus*. Another fossil specimen, labelled "Crooked River," consists of an isolated vertebral plate of a large turtle, apparently the eighth bone of the series. It has the same shape as in *Stylemys niobrarensis*, but is proportionately much shorter in relation with its breadth. It measures 2 inches wide, 1 inch 7 lines long, and 7 lines thick. The specimen probably indicates an undescribed species, which may be named *Stylemys oregonensis*. Two additional fossils are brain casts, probably of *Oreodon superbus*. The cerebral hemispheres are 10 inches 8 lines long, and together about $2\frac{1}{2}$ inches broad.

PARIS

Academy of Sciences, June 17.—A note by M. E. Combescure on a point in the theory of surfaces was presented by M. Chasles.—M. E. Roger read a third memoir on the theory of capillary phenomena.—Father Secchi forwarded a reply to the observations recently presented by M. Respighi in opposition to his remarks on some peculiarities in the constitution of the sun.—M. A. Genocchi read a paper on the intensity of the heat of the sun in polar regions, in which he discussed the calculation of the annual mean heat of the sun within the polar circles.—M. C. Martins communicated a note on the stormy nature and unequal distribution of the rains on the surface of the department of Hérault.—M. A. Bérigny forwarded a note describing the effects produced by the striking of a house by lightning at Versailles on the night of June 6.—M. Lartigue presented an explanation of the mistral.—M. H. Sainte-Claire Deville presented a note by M. Laurence on a compound of oxide of tin with anhydrous acetic acid, produced by heating the two substances together in a sealed tube to 302° F. Upon this paper M. Elie de Beaumont made some remarks, in which he put forward the notion that in the early ages of the world nature may have employed a chemistry different from that which we now see in action in volcanoes and in atmospheric phenomena.—M. Sainte-Claire Deville also presented a note by M. G. Saillard on a new phosphoplatinic derivative of toluidine obtained by heating an alcoholic solution of Schützenberger's ether $Ph (C^2 H^5O)^3Pt Cl^2$, with an excess of crystallised toluidine.—M. Blanchard communicated a note by M. C. Dareste on the natural affinities of the fishes of the family Balistidæ, which he regards as most nearly allied to the Teuthyidæ.—M. Garrigou presented further observations on the constitution of the Pyrenees in reply to a note by M. Leymerie, and in support of his previous remarks on the same subject; and M. A. Brongniart communicated a note by M. G. de Saporta on a revision of the fossil flora of the gypseous deposits of Aix.

June 24.—M. O. Bonnet communicated a note by M. A. Ribaucour on the theory of lines of curvature.—M. Delaunay presented a note by M. Bresse on the determination of the trajectory of a point for which a certain integral is the minimum.—M. J. Morin read a notice of a new voltaic battery with continuous action, acting by sulphate of copper. This consists of a hollow cylinder of copper, in the centre of which is the cylinder of zinc, he two being separated by a cylinder of filtering paper, and the space between the copper and paper being filled with grit, and that between the paper and the zinc with flowers of sulphur. Batteries of this construction have been in operation for twenty months without being replenished.—M. Piarron de Mondésir forwarded a note on the theoretical value of the relation between the two specific heats of permanent gases.—M. de Saint-Venant presented a note by M. J. Boussinesq on the calculation of the velocity of light in bodies in motion.—M. Delaunay communicated a paper by M. F. Tisserand on movements relative to the surface of the earth.—A note was read by M. T. Schlœsing on the solution of carbonate of lime by carbonic acid, containing the results of series of experiments made by the author on this important subject.—A note by MM. Girard and De Laire on the manufacture of aniline colours, was read.—M. P. Champion presented a note on some compounds of paraffin, in which he described an acid, paraffinic acid, with the formula $C^{24} H^{23} NO^{10}$ derived from paraffin by the action of nitrosulphuric acid, and noticed the action of chlorine and bromine upon paraffin.—M. Milne-Edwards presented a note by M. Fischer on the geographical distribution of the podophthalmous crustacea of the Bay of Biscay, in which the author compared this part of the fauna of the Bay with that of the British coast on the one hand, and that of the Mediterranean on the other.—M. C. Bernard presented a further note by M. Oré on M. Liebreich's opinion that strychnine is to be regarded as an antidote to chloral; and a paper by M. Brémond containing an account of some experiments on cutaneous absorption.—M. Duchartre communicated a note by M. Prillieux on the disease of the peach tree known in France under the name of *cloque*, which the author ascribes to the action of a parasitic fungus, described by Tulasne under the name of *Taphrina deformans*.—M. Daubrée presented an examination of the rock-masses of native iron, discovered by Prof. Nordenskjöld in Greenland, of one of which he gives an analysis.—M. Daubrée presented a report on a recent memoir by M. Delesse on the deformations which the strata of France have undergone.—M. de Quatrefages communicated an interesting paper by M. J. de Baye, "On the Prehistoric Caverns of the Marne, belonging to the Neolithic period;" and a second note by M. E. Rivière on the fossil man of the Mentone caves.

BOOKS RECEIVED

ENGLISH.—Concrete Arithmetic: T. H. Orme (Groombridge and Sons).

THURSDAY, JULY 11, 1872

ECONOMIC ENTOMOLOGY

WE have more than once had occasion to refer to the zeal with which the investigation of the insect pests so destructive to our crops of roots and fruits is carried on on the other side of the Atlantic. Three publications now lying before us—two from the United States, and one from Canada—furnish a text for a few further remarks on this subject. They are: "Fourth Annual Report of the Noxious, Beneficial, and other Insects of the State of Missouri," by Charles V. Riley, State Entomologist; "Second Annual Report on the Injurious and Beneficial Insects of Massachusetts." by A. S. Packard, jun., M.D.; and "Report of the Entomological Society of the Province of Ontario for the year 1871." These are all official publications; the two first being Reports made to the State Boards of Agriculture; the last printed by order of the Legislative Assembly. They represent the result of investigations made at the expense of the citizens of the respective States or Province, who are willing to tax themselves in order that the highest scientific experience at their command may be brought to bear on researches whose object is the material improvement of the resources of their country. The only similar efforts to which we can point in this country are the result of private enterprise. The Royal Agricultural Society has long engaged the services of a chemist to analyse manures and feeding-stuffs, and we recorded not long since the addition to its staff of a consulting botanist, and its intention to appoint also a consulting entomologist; but their investigations are carried on exclusively for the benefit of the members of their Society. The Royal Horticultural Society has also arranged for a course of lectures on Economic Entomology, and last year invited competition for prizes for collections of insects to illustrate this subject.

We have so often expressed our view on the relative advantage of having these investigations carried on by private enterprise, or under the direction of the State, that it is needless to repeat it here. Dr. Packard thus forcibly advocates the latter alternative, referring to M. Pasteur's labours in endeavouring to mitigate the scourge of the *pébrine* in the South of France:—"It should be remembered that this remarkable result is due primarily to the most abstruse researches upon microscopic plants by specialists, for the pure love of science. Their cloister studies, put to practical account, save the destruction of one of the largest agricultural industries in Southern Europe. In like manner, had the general Government or individual States encouraged the botanist and entomologist in their studies, and caused them to be turned to practical accounts, we should not have had to give up the cultivation of wheat in the northernmost States; our cotton crop would perhaps have been doubled; and our garden and field crops have regularly yielded a steady return to the producer." It must be recollected that the Federal Government at Washington is now spending large sums in the compilation and printing of enormous numbers of the Monthly Agricultural Reports, in addition to the money devoted by the separate States.

Mr. Riley's Report is one of a series, of which we have already noticed its immediate predecessor, and is a pamphlet of 150 pages, containing, independently of its special object, no small amount of valuable information of general interest. The higher the summer temperature, the greater appears to be the variety of the foes against which the agriculturist has to contend; and their number in the south-western of the United States is legion. After discussing the various insect-enemies to the potato, the cabbage, the apple, the walnut, the grape-vine, and other crops, the causes of their appearance, and the best antidotes artificial or natural, the greater portion of Mr. Riley's Report is devoted to the Silkworm, on the cultivation of which he has bestowed great attention. He describes the various kinds of silkworm, their mode of cultivation, their food in the larva, and imago conditions, and the various enemies, parasitic and others, to which they are subject; and this portion of the Report is illustrated by a number of very well-executed wood engravings. The practical results are thus summed up:—"There can be no good reason why silk-culture may not become one of the industries of this country, or of our State, especially if fostered at the start. I would, however, advise no one to enter into it on a large scale as a business. The raising of silk is seldom lucrative even in the most favourable countries; for in this, as in most other industries, the principal profits accrue to the middle men, reelers, and manufacturers; but on a small scale, and prosecuted in connection with other branches of agriculture and horticulture, it will give the most desirable returns for the time employed. The erection of a few reeling establishments is absolutely necessary to establish this industry."

Dr. Packard's Report treats of similar matters in a similar scientific spirit. It is interesting to note the reciprocity of indebtedness between this country and America in the matter of insect pests; we have received from them the *Phylloxera vastatrix*, so destructive to our vines; and have given them as a set-off our white cabbage butterfly, the *Pieris rapæ*, first introduced into the United States fifteen years since, and now spreading every year with terrible rapidity. It is curious that the chief check on the increase of the larva is a native, not an imported parasite, the *Pteromalus puparum*.

The Canadian Report is interesting, as being the result of the first appropriation of money for these purposes, as far as we are aware, by any of our American colonies. The Entomological Society of Ontario is subsidised by the Legislative Assembly, in order to encourage the devotion of its labours to inquiries of a practical character for the benefit of the colony. The present Report, of nearly 100 closely printed pages, well illustrated with woodcuts, gives promise of much useful work. The Report is divided into sections relating to insects injurious to the apple, grape, plum, currant and gooseberry, wheat crops, potato, cabbage, and cucumber tribe, by different competent members of the Society.

We have referred to these Reports in order to draw from them a lesson as to the direction of the labours of our botanists and entomologists at home. We have among us at least as high scientific talent in these branches as in the United States; but, with a few rare exceptions, this talent is not devoted to researches which

have a definite practical bearing on the welfare of the country. If, as we believe to be the case, the reason of this is that such researches can rarely pay the investigator directly, is not the reasoning sound which would advocate the devotion of public money to purposes which must inevitably yield such large returns to the community at large?

ORIGIN AND DESTINY OF MAN

Man in the Past, Present, and Future: a Popular Account of the Results of Recent Scientific Research as regards the Origin, Position, and Prospects of the Human Race. From the German of Dr. L. Büchner. By W. S. Dallas, F.L.S. (London: Asher and Co.)

The Martyrdom of Man. By Winwood Reade. (London: Trübner and Co.)

THE Science of Man has become matter of public interest. Fluent writers now popularise anthropological evidence, and even use it as a lever to force public opinion in some desired direction. The two clever books before us are in this way remarkable as signs of the times. They treat largely of Anthropology, but not so much for itself as in order to promote materialistic views of philosophy, and advanced schemes of social re-organisation. In briefly noticing Dr. Büchner's "Man," we shall not discuss his general doctrines on their merits. The development theory, if not by acceptance, at least by influence, has so far become part and parcel of modern thought, that it need not be re-investigated *à propos* of each new popular book which advocates it, thereby gaining a share of its prestige. The question for the critic, in judging the work of the self-appointed public instructor, is whether he deals fairly with his public, carefully weighing and testing for them the data which they cannot weigh and test for themselves. We regret to say of a writer so influential in Germany and England as Dr. Büchner, that on the present occasion at least he has not made out his claim to be a public expositor of a very serious subject. In fact, the seriousness of the subject, as demanding extensive study and careful judgment, is just what he fails to appreciate.

Dr. Büchner has the gift of easy exposition. Whether he is descanting on the drift implements and the antiquity of man, or tracing the analogies to successive orders of animals in the successive phases of the human embryo, or giving an account of the approaches made by other animals to the human mind and character, or commenting on theological dogma as opposed to scientific investigation, or pointing out how conscience can adapt itself to contradictory moral standards, or suggesting a re-adjustment of the laws of marriage in the interests of progressive society, his opinions run on with the same shapely smoothness, whether they happen to be solid or hollow. His generalities are put with praiseworthy neatness; his well-selected examples clinch them hard, and just in the right place. He is a capital expounder, when his facts and inferences happen to be sound. Unfortunately, however, his strength of rhetoric is not matched by strength of criticism, as we shall briefly show, choosing the department of anthropology as the trial-ground. In order to make the text of his work readable by the general public, Dr. Büchner has collected the copious materials which might alarm or tire the majority of readers in an Appendix, to which we are to look for actual details or more exact proof of what is enunciated in the body of the work. Looking into this Appendix accordingly, we extract some significant examples.

For a test in Prehistoric Archæology, a passage may be taken (p. 251), which shows our author not to be aware of the distinction in rude stone structures between the *dolmen* formed of several slabs and the single upright standing stone or *menhir*. His words are, "Still older than the so-called 'giants' graves' are the *Dolmens* or stone tables (also called *Cromlechs* or *Menhirs*), very ancient stone edifices, which have been found especially well-represented in Brittany. They consist of upright stones covered with slabs laid transversely upon them," &c. At p. 335 we find Dr. Büchner, on the question of low stages of human language, supporting his views by taking seriously such worthless remarks as the following: "The speech of the Fans of West Africa is, Du Chaillu says, a collection of guttural tones which no one can understand." We beg leave to refer Dr. Büchner to Captain Burton's observations in his "Wit and Wisdom from West Africa," on the grammar and vocabulary of the Fan language, which is in fact but slightly different from allied languages of the coast. In studying the relation between the lower animals and man, of course the problem of savage religion is important, and we looked curiously at Dr. Büchner's evidence. It begins with the following citation (p. 328): "Three large sections of the earth's surface, says G. Pouchet, which are still inhabited by savages, appear to have remained till now exempt from religious notions; they are the interior of Africa, Australia, and the Polar regions." And this in the face of twenty published accounts of the religious beliefs of the Australian and Esquimaux races! There are, it is true, ambiguities in the use of such terms as religion, behind which inaccurate statements may find a refuge. But as to such a subject as the arts of producing fire and cooking food, there can be no ambiguity. We take as they stand (p. 332) a series of statements on which Dr. Büchner relies. "There are still peoples, such as the Dokos, the Andamans, &c., who know not the use of fire, and devour all their food raw. Moreover, that the use of fire cannot be an attribute of humanity as such, is shown by the circumstance that so many peoples have been fire-worshippers, and in part are so still, that, therefore, they considered fire something extra and supernatural. In like manner, when Magellan set fire to the huts of the Marian Islanders, to whom fire was unknown, they looked upon it as a kind of living monster which devoured wood. Also in the Ladrone Islands the Spaniards found the natives unacquainted with the use of fire." We will take these sentences *seriatim*. As to the first, mention may be made of Dr. Mouat's account of the Andaman Islanders' practice of keeping fire constantly burning in hollow trees, covering it up with ashes, and cooking native pigs and fish in these natural ovens. As to the second, the inquiry suggests itself whether the fact of numerous tribes being water-worshippers proves the use of water not to be an attribute of humanity as such? As to the third and fourth sentences, it has to be pointed out that the contemporary account of Magellan's voyage knows nothing of the

Marian Islanders being unacquainted with fire, and looking on it as a living monster; this story was first told by an untrustworthy writer a century or two later.* Finally, after reading the last two sentences referred to several times, we cannot resist the inference from them that Dr. Büchner, putting down as separate data two fragments of one story, did so through not being aware that the Marian Islands and the Ladrone Islands are the same.

Mr. Winwood Reade's "Martyrdom of Man" is more careful as to evidence, though less shapely in arrangement, than Dr. Büchner's work. It begins with ancient Oriental history, then passes to primæval religion as leading up to Christianity and Mohammedanism, next proceeds to discuss negro slavery and its abolition, and lastly plunges into a dissertation on things in general, especially the origin of life, the evolution of orders of plants and animals, the development of the intellectual and moral faculties, and the rise and decline of religion. Mr. Reade's first principle affords him a theory which at any rate places these various topics along lines of continuity. "Mind is a property of matter. Matter is inhabited by mind. There can be no mind without matter; there can be no matter without mind. When the matter is simple in its composition, its mental tendencies are also simple; the atoms merely tend to approach one another and to cohere; and as matter under the influence of varied forces (evolved by the cooling of the world) becomes more varied in its composition, its mental tendencies become more and more numerous, more and more complex, more and more elevated, till at last they are developed into the desires and propensities of the animal, into the aspirations and emotions of the man. But the various tendencies which inhabit the human mind, and which devote it to ambition, to religion, or to love, are not in reality more wonderful than the tendency which impels two ships to approach each other in a calm. For what can be more wonderful than that which can never be explained? The difference between the mind of the ship and the mind of man is the difference between the acorn and the oak." Following this all-comprehensive doctrine, Mr. Reade works out in well-turned paragraphs the evolution of animal and human faculties, the development of science and art, the rise and change of social and moral laws. He especially dwells upon the imperfections and mistakes of early ages, which, while afflicting the world with temporary evil, yet prepare it to attain in later times to better things. This is what he means by the title of his book, of which the historical and scientific parts seem intended to give weight to a polemical point, that of urging all enlightened men to take part in the great work of demolishing one of those institutions which, once the highest attainable, has now become injurious. "Christianity must be destroyed." "I give to universal history," the author writes in his conclusion, "a strange but true title—'The Martyrdom of Man.' In each generation the human race has been tortured that their children might profit by their woes. Our own prosperity is founded on the agonies of the past. Is it therefore unjust that we also should suffer for the benefit of those who are to come? Famine, pestilence, and war, are no longer essential for the advancement of the human race. But a season of mental anguish is at hand, and through this we must pass in order that our posterity may rise. The soul must be sacrificed; the hope in immortality must die. A sweet and charming illusion must be taken from the human race, as youth and beauty vanish never to return."

* See Tylor, "Early History of Mankind," p. 234.

Mr. Reade's plan of not making particular acknowledgment to the writers whose facts and ideas he incorporates, is likely to mislead his readers, some among whom may fancy him a great original thinker, while others will certainly set him down as a mere compiler. It is not our business to discuss either his fanatical anti-Christianity, or his promised "Religion of Reason and of Love;" but so far as concerns Anthropology, his book shows the results of considerable reading and observation, conveyed with a certain power of word-painting and epigram. Now that he has delivered himself on the great question of modern thought, and has probably ascertained that no individual martyrdom awaits him apart from the rest of his species, we should recommend him to turn his experience and ability as an ethnologist to doing more solid work in some special department of his science.

OUR BOOK SHELF

The Scientific and Profitable Culture of Fruit Trees. From the French of M. Du Breuil; adapted for English cultivators by W. Wardle. Second edition, carefully revised by George Glenny. (London: Lockwood and Co., 1872.)

THREE practical men have been concerned in the writing and editing of this little book, which is on all grounds well worthy of a place on the bookshelves of every gardener and grower of fruit-trees. It professes to direct the gardener in all the operations necessary, from the insertion of the graft to the completion of the tree, and the proper management through all its stages; and the instructions in all the various kinds of grafting are full and comprehensive. The first portion treats of the different modes of grafting, pruning, and training, and instructs in the mysteries of grafting by approach or inarching, branch grafting, cleft grafting, crown grafting, side branch grafting, and budding, or shield grafting. The main part of the book is then devoted to directions as to the mode of cultivation of the pear, apple, peach, plum, cherry, and apricot, and their best varieties. The portions of the work which were specially adapted for French cultivators have been modified or enlarged by the editor, and the language is throughout plain and simple. It is embellished also by nearly 200 illustrative woodcuts.

Reports of the Mining Surveyors and Registrars (Victoria) for the quarters ending June 30, September 30, and December 31, 1871. (Melbourne, printed by authority.)

THESE reports show that the mining operations in Victoria continue to be assiduously prosecuted, the total yield of gold during the three quarters being estimated at 1,055,808 oz. 4 dwt. 4 gr., of which 524,990 oz. 7 dwt. 21 gr. were got from alluvia, and 530,817 oz. 8 dwt. 7 gr. from quartz reefs. The quantity of gold, the produce of the colony, exported during same quarters, amounted to 916,114 oz. 6 dwt. During the quarter ending June 30, the greatest yield of gold occurred, and the largest quantity was exported. But the yield and export of each of the three quarters approach pretty nearly to the same figures, indicating that the working of the mines has got into a settled state, and that the produce for some time to come may be expected to be proportionate to the capital em-

ployed. A number of tables give some interesting details relative to the number of miners, the machinery in use, and its value, from which may be gathered some idea of the extent and importance of the several gold fields in the colony. Of these fields, that of Ballarat appears at the head of the list, showing a total number of miners employed of 13,892, the approximate value of mining plant being 516,825*l.*; 134½ square miles of auriferous ground are actually worked upon, and 189 auriferous reefs have been proved. In this district also occur the deepest shafts, two of which reach the depths of 866 ft. and 900 ft. respectively. The price of Ballarat gold varies from 3*l.* 13*s.* 6*d.* to 4*l.* 2*s.* 6*d.* per ounce, the latter appearing to be the highest price obtained for any gold in the colony. In this mining district 78,502 tons 10 cwt. of quartz were crushed during the last quarter of the year, yielding 5 dwt. 19·42 gr. of gold per ton; the average yield in the different gold fields being very variable. But in considering the relative importance of each district, we are reminded by Mr. Brough Smyth, the Secretary for Mines, that the table relating to machinery should be examined and compared, from which it appears that it is not always the mines that show the greatest yield of gold which give the largest return to proprietors. An interesting feature in these reports is the description by Dr. F. von Mueller (Director of the Botanic Garden of Melbourne) of certain new vegetable fossils which are met with from time to time in the deep auriferous drifts of older Pliocene age. These consist of the fruits of plants which, according to Dr. Mueller rejoiced in a milder climate, and displayed forms of tropical grandeur now foreign to the spot. Five genera are described and illustrated with beautiful lithograms. Of these, among fossil genera *Phymatocaryon* comes nearest to the extinct *Cupanoides*, *Tricarpellites*, and *Wetherellia* of the London Clay. Another genus, *Trematocaryon*, bears no very close alliance with any genus among living or fossil plants. The remaining genera are *Rhytidotheca*, with some affinities to *Chloroxylon* and *Flindersia*, *Plesiocapparis*, the real affinity of which is doubtful, and *Celyphina*, which appears to belong to the order of Proteaceæ. We are glad to learn that many other fossil remains have been secured, and are now under examination by Dr. Mueller. For the collection of these fossils palæontologists are indebted to the enlightened zeal of Mr. John Lynch, mining surveyor and registrar. When one looks over the long list of surveyors and registrars employed by the Colonial Government in gathering statistics, we can only hope that some, if not all, of these gentlemen will follow Mr. Lynch's example, and thus be the means of increasing our knowledge of the "old world" of Australia.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Rigidity of the Earth and the Liquidity of Lavas

I WAS glad to see the powerful argument in favour of the solidity of the earth which Sir William Thomson has deduced from its great rigidity, republished in NATURE of January 18, since, though never attacked, it has been ignored by those who hold a contrary view. In a lecture before the Royal Institution in May 1867, I appealed to it in support of the notion which I have long maintained of a globe solidified from the centre; and I remember that for that and for other heresies in my lecture I was sharply attacked in the *Geological Magazine*, and in turn defended myself as best I might in the same magazine for February 1868. I there said that "the conclusions of Hopkins from the phenomena of precession and nutation, the investigations of Archdeacon Pratt on the crushing effect of immense mountain masses like the Himalaya, and the deductions of Sir William Thomson from the phenomena of the tides, showing the great rigidity of the earth, are so many concurrent evidences that our planet, if not actually solid to the centre, has a crust far thicker than can be accounted for by the theory of a liquid globe, covered only with a crust resulting from superficial cooling." This discussion of the subject at that time seems to have had the effect of bringing to the front the defenders of the latter theory, which, in the popular mind at least, has a mythological rather than a scientific foundation. It was, therefore, well that Sir William Thomson should repeat his arguments.

Mr. Fisher has in this connection, in NATURE for January 25, referred to the distribution of fluid ignited matter within the earth, and to the relation of volcanoes to great lines of elevation, which would seem to show that the local distribution of such matter may be connected with these lines. He says, "I have suggested that this fluidity may arise from a diminished pressure beneath mountain ranges, owing to their mass being partly supported by the lateral thrust which has upraised them," and adds, "If any of your correspondents can propose another explanation of this remarkable coincidence compatible with the supposition of a rigid globe it would be interesting to know it."

My present object in writing is to call attention to the explanation proposed by me in the *Geological Magazine* for February 1870, conceiving, with Archdeacon Pratt, that the condition of things beneath a great mountain mass is one of increased rather than of diminished pressure. I there said, "Pressure, which in the first case, that of simple fusion of anhydrous materials, prevents liquefaction by preventing expansion, in the second case (that of igneo-aqueous fusion, or liquefaction at high temperatures, by the aid of a small portion of water, as maintained by Scrope, Scheerer, and Elie de Beaumont) on the contrary, favours liquefaction by promoting the solution of the water-impregnated mass." As Sorby has shown, a conversion of mechanical into chemical force appears in the increase of solubility under pressure. In other words, pressure prevents fusion, when, as in most instances, it is a process of expansion; but favours solution, which is, with few exceptions, a process of contraction.

"Now since I place the seat of volcanic action in a region where solution, rather than simple fusion, is the cause of liquidity, I am led to consider pressure as one of the efficient causes of the liquefaction of rocks, and to regard its diminution as leading to solidification." (See also Amer. Jour. Science, ii., l. 27).

Montreal, June 21 T. STERRY HUNT

Fouling of the Nile

THERE is an account—of which I have unfortunately lost the reference—of the Nile becoming crimson and putrid, and its fish being killed, during the historic period, seemingly by microscopic algæ. If any learned contributor could tell me where I can find this fact recorded, and could give me any details of similar phenomena, he would do me an especial kindness.

Chester, July 8 C. KINGSLEY

Volcanoes of Central France

AFTER carefully reading through the two extracts from Sidonius and Avitus contained in your number of May 30, my impression was that notwithstanding some manifest improbabilities, the conclusion was inevitable that earthquakes and other volcanic phenomena had actually been witnessed at Vienne. However, after examining all the facts of the case, a theory has occurred to me by which both accounts may be consistently explained without any such phenomena having occurred there at all. It would only remain to be shown that my supposed facts are not contradicted by evidence actually on record.

First, as to the persons:—The whole matter centres in the great Gallic family of Avitus, belonging to Auvergne. The most distinguished member of this family was Marcus Mæcilius Avitus, a person of so much importance that in the year 455 he became Emperor, but so little fortunate that in October 456 he was conquered and driven from the throne. He was allowed to become Bishop of Piacenza, but fearing for his life, returned to Auvergne and took refuge in the Church of St. Julian.* We find shortly afterwards two members of this family in possession of the See of Vienne, father and son, in succession, and the latter was the author of our Homily.

It seems, therefore, highly probable that the bishopric was in the gift of the family, or in some way dependent on it. In the year 463 we first find St. Mamertus in possession of the

* According to Gibbon he died on the way; the one certain fact is that he was buried there.

See, and his brother C. *Ecdicius* Mamertus seems to have been closely connected with it; indeed, he seems to have composed music for the choir. We are warranted in conjecturing that this family must have had intimate relations with that of Avitus. The name of the author of the Homily is A. *Ecdicius* Avitus; Sidonius Apollinaris was son-in-law of the Emperor Avitus, and his intimacy and correspondence with "Lord Patriarch Mamertus" confirm the supposition.

We have seen that M. M. Avitus went to Rome as Emperor, A.D. 455. The first time we hear of Mamertus as Bishop of Vienne is A.D. 463. What, then, is the probability of the following facts?

When Avitus went to Rome, he took with him many of his intimate friends and connections, and among them St. Mamertus. He obtained for Mamertus some Italian See, of which the principal town was situate at no great distance from Vesuvius. It was walled, had a large forum, and was partly inhabited by the nobility of the country. Upon the expulsion of his patron, Mamertus exchanged to the See of Vienne, or obtained that See by some other means. During the short time he was in Italy he witnessed those earthquakes and showers of ashes described in the letter and the Homily.

Assuming these facts, how will they agree with the statements in these documents, and with the known history of Vesuvius?

It is clear, from the letter of Sidonius, that the reason why the people of Auvergne observed the Rogations was not the fear of earthquakes, but of the incursions of the Goths, against whose advances they formed the chief barrier; they lived in the midst of the "surrounding terrors," yet Sidonius himself had to make inquiries and get information (*Sciscitatio*) in order to become acquainted with the volcanic phenomena: he nowhere says that "the city divinely committed to Mamertus" was Vienne, and all the circumstances are connected with Mamertus personally, and with a town only through him.

St. Avitus succeeded his father A.D. 490, and died A.D. 525. At what precise date he wrote the Homily I suppose is unknown; it may, perhaps, have been written before he was Bishop. The date of his birth seems to be unknown, but he may very well have been old enough to have been with his father in Italy, and as a youth have witnessed the phenomena that were seen by Mamertus; and in the congregation that listened to the Homily, there may still have been "many" who had been there also (with the army?), and had also seen them.

The words "at that time" mean that the earthquakes, &c., occurred at the same time with the attacks of the Goths on the inhabitants of Auvergne and Vienne.

One astonishing circumstance is that the Rogations, though instituted (in Gaul at least) by Mamertus, say between 456 and 463, had already obtained in "nearly the whole world;" evidently no such rapid and wide extension could be due to the fear of earthquakes; but it is easily understood, if they were considered to be a protection against the attacks of barbarians; the time of their celebration shortly before Whitsuntide would, I suppose, be about the time of preparation for the usual summer campaign.

But how account for a Bishop of Vienne instituting at Vienne a ceremony which is alleged to have been occasioned by events that happened in Italy? Thus:—Mamertus, who had no previous knowledge of volcanic action, would be greatly struck by what he saw; and even to the Italians these manifestations were probably a novelty. Vesuvius had been comparatively quiet for 200 years, and these (by hypothesis) were among the first intimations of that renewed fury which reached its climax in 472, and is mentioned by Procopius (I have no access to his work).*

Struck with terror, the idea of the Rogations occurred to him while in Italy, possibly he may have instituted them there; but it agrees better with the claim of Vienne to suppose that before he had the opportunity of carrying out his idea, he found himself again in Vienne, and first instituted them there, not against earthquakes, but against the barbarians.

The two things together, the earthquakes and the wars, suggested to him the possible approach of the awful time indicated by Christ (Matt. xxiv. 15)—"Cum ergo videritis abominationem desolationis," &c.; hence the "abominabilia" and the "doom of desolation" of the Homily. The "magna tribulatio" would well agree with the constant wars, and the "ineffable distress" occasioned by them.

Norwich, June 5 HENRY NORTON

* A few days after writing this I read the passage in Procopius, and found that he expressly attributes the institution of Rogations to the action of Vesuvius.

The Wanderings of the Esquimaux

It is very gratifying to find that Mr. Howorth, whilst holding the position he has taken up with augmented force, has accepted, in the same kindly spirit in which they were written, the observations on the migrations of the Esquimaux which I was led to make after reading his very excellent letter in NATURE of May 9.

Mr. Howorth now brings forward the language of the Esquimaux in support of his views. This may be a strong point, although, if I remember rightly, one or two distinguished ethnologists think differently. As for myself, having little or no knowledge of languages, I can express no opinion one way or other.

Open as I am and shall be to conviction, and ready to give up my opinion cheerfully if proved wrong, I find that so far, the able arguments brought forward by Mr. Howorth have not in the slightest degree unsettled my belief in the truth of the Esquimaux tradition, communicated through interpreters whose competence I proved in a very satisfactory manner, at the same time that I ascertained the reliability to be placed on information transmitted from one to another by the Esquimaux. This I did by comparing information given by the natives of Repulse Bay, through my interpreter, with portions of the narratives of Arctic explorers of distinction (with which it agreed very closely) written in the one case more than twenty, and in the other more than thirty years before; of course neither the Esquimaux nor the interpreter knew what was in these narratives.

Mr. Howorth quotes numerous authorities, and I have no doubt does it so correctly that there is no necessity to look them up. These I shall now endeavour to answer, and as nearly as possible in the order in which they appear in his letter.

I do not think that the fact of the "Arctic Highlanders" building "stone igloos instead of snow huts," or their "ignorance of boats, either kayaks or oomiaks," makes any "broad distinction" between these people and the "American Esquimaux."

In the far west, that is, from Behring Strait to the Mackenzie River, the Esquimaux live in wooden houses during winter, probably because driftwood is abundant. They also have both kayaks and oomiaks.

As you go eastward and get near the Coppermine River, snow-huts form the winter shelter, probably because little or no wood is to be found, and a stone house without fuel to make a fire, is, as I know by experience, much colder and more comfortless than a snow-house under the same circumstances. The food of these natives is principally reindeer, musk cattle, and fish, with some seals, but neither whales nor walrus, as far as I could learn, to give fat for fuel. Here, also, the oomiak or large luggage boat disappears, it may be because the Esquimaux are less numerous, more scattered, and live in smaller communities, and do not require it. Another reason may be that the sea is more ice-encumbered. The kayak is, however, still in use, and when it is requisite to transport a family or a heavy load across water, two or more of these are fastened together, poles or paddles laid across them, and thus a kind of platform is constructed, which will carry very considerable weights in perfect safety.

This state of things prevails as far eastward as the great Fish River. Boothia, Gulf Committee, Repulse and Hudson Bays, but as the Esquimaux travelled northward to latitudes 76° and 77° by the route I have supposed them to do, as described in a former letter, the difficulty of building kayaks would be increased in consequence of scarcity of wood to make the frames.* The necessity for them would also become less, as the sea became less free from ice, and if, as I suppose, they chiefly hunted and lived upon reindeer and musk cattle. The usual season for killing seals is before the ice breaks up, so no kayak is required for that purpose.

From the description given me of the numerous "moss-grown ruins of deserted huts" seen near Smith Sound and on the Parry Islands, I am led to believe that many of them were not dwelling places at all, but the ruins of large stone "caches," such as are found in many places on the shores of America, where the natives have collected a quantity of provisions, round which stones are built in a very solid manner as a protection against the attack of the fox, the wolf, their own dogs, and, worst of all, the wolverine.

Let me now say a few words about the Arctic Highlanders of

* In 1846 the Esquimaux of Repulse Bay had plenty of wood, but in 1854 many of them, who had been hoarding up seal skins for the purpose, could not build kayaks, because they had no wood to make the frames of.

North West Greenland. I suppose these build their igloos of stone because they have no wood, and prefer this kind of house to a snow hut, because the walrus which they kill in great numbers, and which, according to Drs. Kane and Hayes, forms their principal food, affords abundance of fat for fuel. A stone house with fire is warmer than a snow hut without it.

As the Esquimaux, of all people I have ever met with, most readily adapt themselves to circumstances at very short notice, I believe that these Arctic Highlanders could under every difficulty build kayaks for themselves, were they absolutely necessary, otherwise how can we account for the Esquimaux in the south of Greenland (whom Mr. Howorth believes to be the descendants of these Arctic Highlanders) having built both kayaks and oomiaks almost identical in form and construction with those in use among the "American Esquimaux" of Behring Strait and the Mackenzie, several thousand miles distant, with whom they could have no direct communication? This has always appeared to me a very curious circumstance difficult of solution, except by supposing that the "Skrelings" crossed Davis' Strait at its narrowest part from Cumberland Island to Greenland, a distance of 200 geographical miles—a theory which I do not think so probable as the one I have already advanced.

"The Arctic Highlanders have become alarmed at the rapid diminution of their numbers through famine and disease."

This feeling is not peculiar to the Arctic Highlanders, for both at Repulse Bay and at the Coppermine River a very similar story was told me.

Between 1847 and 1854, the dates of my two visits to Repulse Bay, forty or fifty of my old friends in that neighbourhood—men, women, and children—had died in one season, and nearly all from starvation, caused, I was told, by one of those erratic migrations of animals I have already mentioned.

Although there is every probability that the musk cattle, of which skulls are found scattered along the shores of Smith Sound, had been killed by the Esquimaux, the "absence of the lower jaws" is no proof that they were so killed. Wolves, foxes, or bears, would carry off these lower jaws and very likely "break them up," but the head itself would be rather an uncomfortable burden for the two first-named animals, and would not afford much nourishment to Bruin, and even his strong teeth would find an old musk bull's skull rather a hard nut to crack if he did attempt it.

"The American Esquimaux never go from their own hunting-range for any distance to the inhospitable north."

It is very difficult to define what "any distance" may mean, but I have known them go several hundred miles in one season to look out for fresh hunting-grounds or seas, either north or south, and if they find game they remain there. If the game moves away, the Esquimaux will follow it, whether north or south, if not stopped as trespassers by some of their own countrymen who have had previous occupation.

When I went to Repulse Bay in 1853, I was surprised and disappointed at finding no Esquimaux—for we wanted dogs from them—where a very considerable number had been in 1846-7. In the spring (1854) we found that none had wintered, as far as we could learn, within 200 miles of our winter quarters. The Chippewayan legend told by Sir John Franklin is well known to the Hudson's Bay Company's people.

The Indians resorted in old times to the deposits of native copper on the Coppermine River to obtain that useful metal, with which to make spear and arrow heads, &c.; and it was probably on one of these occasions that an Indian woman may have been carried off "across the sea" to Victoria on Wollaston Land," some points of which are within sight of and at no great distance from the Continent. Very likely, instead of being kept in slavery, some good fellow made her his wife, and treated her as such, much more kindly than she would have been treated among her own countrymen.

In fact, although the habits of the Esquimaux near the Coppermine have nothing of the Indian in them, the face and form of several that I have seen differ widely from the true Esquimaux type, thereby indicating a mixture of blood or races.

That admirable traveller and keen observer, Mackenzie, "certainly knew the country well," but he did not know much of the Esquimaux, for the simple reason that he had very little opportunity of becoming acquainted with them. As an authority on anything relating to the Indians, either east or west of the Rocky Mountains, no man could be more reliable.

Mackenzie says at p. 406 of his book, "They (the Esquimaux) never quit the coast." I think Sir Alexander Mackenzie meant by this that they never went inland; the only interpretation which would, I think, give his opinion any weight. If in saying "they never quit the coast," he meant that they never crossed the sea or ice to other lands or islands to the north, which he by his own observation could not possibly have known, it would be in perfect contradiction to the Chippewayan legend of the woman being carried across the sea, &c., and to our present knowledge.

It is not at all necessary for the American Esquimaux to cross Behring Strait to enable them to obtain articles of Russian manufacture from the Tchuktchi, nor for these to cross over to America for this purpose. A number of Russian trading-posts have for very many years been established in Russian America (now Alaska), and these traders have carried on a large and direct traffic in articles of Russian manufacture with the Tchuktchi and Esquimaux.

It is that very "fragment" of so called Tchuktchi, of Tchuktchi Ness, found in the extreme north-eastern part of Asia, and a few of the Kamskatkans, whose language, custom, or physique resemble, to some extent, those of the Esquimaux, which I humbly think give strength to my belief in the original eastward migration of those curious people.

That there may have been a subsequent re-migration, so to speak, of Tchuktchi from America westward across Behring Strait to Asia, is, I think, very probable.

The Esquimaux and Tchuktchi of America, although they meet to trade for mutual advantage, are by no means friends, for they are (or were very recently) often at war with each other.

I can scarcely think that the American Esquimaux have been "sophisticated" by contact with the Indians. At the present time they differ from the Indians in every particular. In their dress, in their manners, in their mode of pitching their tents, of cooking and eating, fishing and hunting, in the form of their fish spears and hooks, in sewing, in the way of treating their wives, &c. Indeed, even at Churchill, where they come much in contact with the Indians, they seem to have acquired none of their habits or customs.

This letter has increased in length far beyond the limits I had contemplated, and I am almost ashamed to forward it to you with any hope of its finding a place in the columns of NATURE, but I felt almost bound to write something: first because an answer of some kind was required to the several arguments so well and ably used by Mr. Howorth, and secondly because I wished to comply with the hope he so pleasantly expressed that I would bring orward some more facts on my side. JOHN RAE

The Aurora of Feb. 4

IN the February number of NATURE just to hand I find an interesting account of this aurora. It may interest your readers to know that a very fine aurora was visible at Eden, 230 miles south of Sydney, at the same time. The notice sent me states that the aurora was visible from 1 A.M. to daylight of Feb. 5 (*i.e.* from 3 P.M. to 7 P.M. Feb. 4, Greenwich time); the auroral light extended from S.E. to S.W., and to an altitude of 60°. No other particulars were sent by the person who saw it; but it would appear that the auroral display must have commenced before it was observed in Europe. H. C. RUSSELL

Sydney Observatory, May 15

THE ZOOLOGICAL STATION AT NAPLES

LETTERS from Naples inform us that the construction of the building for the Zoological Station is now advancing rapidly. As the building is close to the sea, the foundations had to be laid with especial care, the more so as the heavy pressure of the aquarium tanks, the laboratory tanks, the library and the collections, would require even on ordinary ground some precaution.

We are glad to hear besides that Dr. Dohrn is most effectively assisted in the technical parts of the construction by Mr. W. A. Lloyd, of the Crystal Palace Aquarium, Sydenham. This gentleman, having been in friendly relations to Dr. Dohrn some years ago, when still in Hamburg, has obtained from the Board of the Crystal Palace Aquarium permission to render all possible help to the Naples station, as to an institution of a purely scientific character. Whoever knows the technical difficulties of

such a construction will be exceedingly glad that so experienced a man as Mr. Lloyd lends his assistance in so disinterested a way to an establishment which we trust cannot fail to exert a powerful influence on the progress of scientific Biology.

We are further informed that Dr. Dohrn has already received considerable presents for the future library of the Zoological Station. The celebrated firm of Engelmann, Leipzig, has sent all works published by it on biological topics, and which had not yet formed part of Dr. Dohrn's private library. The value of these books exceeds 100*l*. Besides this Vieweg, of Brunswick, has sent all that he has published on Biology. Theodor Fischer, of Cassel, the well-known publisher of the magnificent "Palæontographica," has also made very liberal grants. Others are promised. We trust our English publishers will not hesitate to send their publications on biological topics as soon as application is made by the administration of the Station.

The entrance of these books, and of whatever goods may be sent to the Station, is freed from any duty by the Italian Government. Dr. Dohrn hopes to obtain in short time, from a great steamboat company, free transport for all the objects sent from England to the Station.

On all these and other points we hope to give more full and special information at the beginning of next month, when the Committee for the Foundation of Zoological Stations in different parts of the World, will publish its Report to the British Association.

ON ALPINE MAPS

MR. LESLIE STEPHEN says that the Alps are the playground of Europe, and he is not far wrong; but the majority of the boys who frequent this playground are acquainted with only a very few of its nooks and corners, and not a single one of them can pretend to know the whole of it. The Alps are not likely to be thoroughly explored for several generations yet to come; and I doubt not that it will be possible for men half a century hence to spend their ten or twelve seasons in the Alps, and still to find at the end of their time valleys which have not been described or even visited.

The Alps are very imperfectly known, and they are still more imperfectly mapped. A complete map of the entire chain of the Alps is yet wanting. I mean one embracing the whole of the land between the Mediterranean on the south and Munich on the north, and from the valley of the Rhone on the west to the frontiers of Styria and Hungary on the east. I believe it is correct to say that there is no map in existence on a scale of $\frac{1}{500000}$ of nature (or on nearly so large a scale) which contains the whole of the above indicated regions; and even the scale of $\frac{1}{500000}$ is much too small to permit justice to be done to the intricacies of the chain. So long as the Alps remain divided between several countries it is not likely that we shall possess a complete map of them upon an uniform scale; and as it is improbable that boundaries will be rearranged for the formation of an Alpine State, and more so that private individuals will be enterprising enough to meet the want, it is in the highest degree unlikely that a complete map of the Alps will be produced within many years. Nevertheless, materials for a complete map are rapidly accumulating; the greater part of the chain has been surveyed with considerable accuracy; and the attention of the reader is now invited to some of the more important of the maps which have been, or are being, produced after these surveys.

The Swiss Alps have been surveyed with a thoroughness which leaves little or nothing to be desired. The Government map of Switzerland, on a scale of $\frac{1}{100000}$ of nature, in 25 sheets, besides possessing in a most remarkable degree the essential qualities of accuracy and clearness, has, regarded as a whole, a unity and perfection which place it far in advance of any other maps of mountainous countries with which I am acquainted. I have carried it in hand over a large part of Switzerland; and whilst I have never been able to detect anything more than trifling inaccuracies, I have been continually filled with admiration for the consummate ability displayed even in its most minute details, and for its almost faultless expression of every variety of mountain form. It would be a poor compliment to it to say only that one can distinguish upon it slopes from precipices, jagged ridges from rugged ground, and the "ice-falls" of the glaciers from the gentle undulating snowy slopes of the upper regions. One can do much more than that. When its conventional methods of expression have been mastered (and it must always be remembered that line engraving is necessarily conventional), the peaks detach themselves from the valleys and soar aloft, and the mountaineer sees the Alps before him with all their marvellous diversity of architecture; nay, more, he can fix his line of assault, and will say, "Here, if anywhere, the summit may be gained."

The effect of the whole map is as satisfactory as its details. The junctions of the sheets are admirably effected and are scarcely perceptible,* the relief of the hills gradually augments from the lowlands upwards, and the *massifs* are projected—as it were embossed—with astonishing power; whilst the great features of the country (such, for example, as the upper valleys of the Rhone and of the Rhine) are depicted so clearly that a single glance is sufficient to fix them indelibly upon the memory. As a work of art (irrespective of its other merits) this map has extraordinary excellence, and, taken as a whole, I believe it to be perfectly unique.

There were special maps of several of the Swiss cantons before the great survey was undertaken, but the map in 25 sheets is the first general official map of Switzerland that has been produced. It is drawn with what is termed *oblique light*—that is to say, with the light proceeding from the left-hand top corner to the right-hand bottom corner; and this treatment (which the Swiss Staff maintain with reason is the natural and the only effective system possible for a mountainous country) is employed consistently through all the sheets. A great part of the artistic effect of the map when the sheets are joined together is due to this treatment. The system of *central light*, which is sometimes adopted for maps, does not answer for a mountainous country; for it is evident, if it is employed in a map with numerous sheets, that each sheet becomes isolated from the surrounding ones, and unity of effect is impossible.

The claims of the draughtsmen and engravers of the Swiss map are deserving of especial recognition. It could not have been produced in its wonderful perfection unless every person employed upon it had been devoted to the work, and possessed of rare ability. But I believe that the reason of the extraordinary uniformity in the excellence of its parts, and of the unity of the whole, is found in the fact that the entire drawings and plates (and a great part of the survey†) were executed under the direction of a single head, namely, that of General Guillaume Henri Dufour.‡ The map is popularly and properly termed the "Carte Dufour."

The Swiss are keenly alive to the value and uses of good maps, and since 1869 have commenced a great one, which, in its dimensions at least, dwarfs the Carte Dufour

* For an example of the admirable way in which these sheets will join together, the reader is referred to a map of the Canton Uri, issued by the Swiss Statsbureau in 1867, which is composed of portions of four of the sheets of the Dufour map.

† The triangulation was commenced at the end of the last century by the cantons, and in 1828 was taken into the hands of the Confederation. The triangles of the first order were brought to a conclusion in 1840. The first sheet appeared in 1845, and the last one in 1864. In connection with the survey the names of Bétemps, Coaz, Mohr, and Colonel Siegfried should be mentioned. The last-named gentleman is, since 1864, director of the Topographical Bureau.

‡ Born 1787; entered the Federal Staff 1817; Colonel 1827.

to insignificance. The map of which I now write, when complete, will be in 546 sheets. The portion comprising the plains and the Jura will be on the large scale of $\frac{1}{25000}$, but the Alpine portion will be upon a scale of $\frac{1}{50000}$. As yet only 26 sheets are published. The large scale of this map admits of the introduction of details which would have overcrowded the Carte Dufour, and there is, indeed, scarcely anything omitted from it which could be inserted. Even the erratic blocks of the Jura are laid down. The rivers and torrents are printed in blue ink, the lettering and outline of the map is in black, and there is a third printing, in red, for contour lines. Originally it was intended to have had a fourth printing, in green, for the sake of the forests; but the idea was abandoned from considerations of expense. The engraving of the lowland portion of this map is of the most exquisite character, and the Alpine portions (which are lithographic) are extraordinary examples of drawing on stone. The published sheets have not, however, the relief which is such a picturesque feature of the Carte Dufour, and which makes that map so popular and so valuable for educational purposes. Notwithstanding this, the larger map will be found to be incomparably the more useful of the two. The contour lines are laid down on the Alpine portion at a height of 30 metres (= 100 Swiss feet), and on the lowlands at a height of 10 metres above one another. One can therefore determine at a glance the height of any point upon mountains, glaciers, or snow-fields, within a few feet; whilst the largeness of the scale renders it invaluable for purposes for which the Carte Dufour could not be employed.

There is also at the present time a third map of Switzerland being produced at Berne, which is a reduction of the Carte Dufour. This is upon the scale of $\frac{1}{250000}$, and will be in four sheets. Two sheets are already published, a third is complete so far as Switzerland is concerned, but is awaiting details of the Italian Alps, and the fourth sheet is scarcely commenced. The engraving of this map is not less admirable than of those which have been already enumerated; and as it will be sold at 10 fr. for the four sheets, it will be one of the cheapest, if not the very cheapest, copperplate map ever produced.*

There are, therefore, existing or in progress three maps of the Swiss Alps, each of which may be adopted with confidence as a basis for other maps; but if we pass to the French, Austrian, or Italian Alps we shall find a great inferiority in the materials at our command. The French Alps have been, perhaps, better surveyed than the Austrian, and the Austrian than the Italian; but all these countries are destitute of maps possessing anything like the perfection of the Swiss ones.

The survey of the Etat Major, for the great map of France in 258 sheets (subsequently extended to 263 sheets, in consequence of the annexation of Savoy), was commenced very many years ago, but there are about 20 sheets still remaining unpublished, and almost all of these belong to the Alpine part of the country. Sheet 189, published in 1866, is indeed the only one yet issued which embraces any very lofty peaks; and this one contains the whole of the so-called Pelvoux *massif*, which includes numerous splendid mountains ranging in height from 3,700 to 4,100 metres. The principal triangulation may have been performed, for aught I can say to the contrary, with the utmost precision; but there is in the engraved sheets of the Alpine portions of the map a general want of the intelligent rendering that is found in the Carte Dufour, and such inexactness in the topographical details that one's confidence is shaken in the whole work. I cite by way of example the *massif* of the Meije (3,987 metres), the highest mountain in the Alps which remains unascended. The glaciers and its ridges, both on the north and on the south sides, are very inaccurately represented, and upon the spot are scarcely recognisable; and in other places, even where attention has manifestly been paid to details, the work is very devoid of character, and has been freely generalised. One can only conclude, in regard to these matters, that the engineers either considered that details of the upper regions were of no importance, or else that they were ignorant of the meaning of the things which they regarded. No sheets have been published to the south of No. 189, and thus the greater part of the department of Hautes Alpes, and the whole of the departments of the Basses Alpes and of the Var (to say nothing of Nice) remain unmapped. It is, I believe, chiefly on account of the want of good maps that so few persons travel for pleasure in this beautiful corner of France. The means of communication are good, and living is cheap, but it is rare indeed to meet with a tourist anywhere; and the solitary pedestrian is likely to be mistaken by the natives (as I have been several times) either for a pedlar selling images of the Holy Virgin, or for a dealer in looking-glasses.*

The range of Mont Blanc, which partially reverted to France in 1860, was until quite recently one of the worst mapped portions of the entire chain.† Upon the annexation of Savoy, Captain Mieulet, of the Etat Major, was set to work to connect this part of the new territory with the great map of France. But before Mieulet's work was reduced, and indeed almost before his survey was completed, the range was mapped by an amateur, and the honour of first presenting to the world an accurate plan of the most important part of the greatest chain of mountains in Europe was secured by an Englishman. Mr. A. Reilly (the English amateur to whom I refer) in 1863 determined trigonometrically no less than 200 points, and in the winter of 1863-4 reduced his work to shape, and presented his map to the English Alpine Club. Its publication was immediately resolved upon, and in 1864 Mr. Reilly went over the ground again to correct his work. In June 1865 his map was published at the cost of the Alpine Club, in chromo-lithography, upon a scale of $\frac{1}{80000}$ under the title of "The Chain of Mont Blanc." In the mean time it had been represented in Paris that it would be a great advantage for Captain Mieulet to extend his work beyond the frontiers, and he accordingly carried his survey as far as Courmayeur. A special sheet on the scale of $\frac{1}{40000}$ was promptly engraved from the materials he accumulated, and was published in 1865 by order of the late Minister of War, Marshal Randon.‡ This map, however, included the central portion of the chain only, and Mr. Reilly's map remains, I believe, the only trustworthy complete map of the whole of the chain that is in existence.

In accuracy there is probably little difference between these two maps. The French one is superior to the other in giving numerous altitudes, but the English one has the merits of greater clearness and picturesqueness. Mieulet, on his survey, discovered that the highest peak of the Aiguille de Trelatête was only 3,932 metres, whereas an altitude 1,000 ft. greater had been previously assigned to it. Reilly, on his part, demolished the Pointe des Plines, a fictitious summit, which he showed was identical with the Aiguille d'Argentière, although it had in former maps been laid down as a mountain separate and distinct. Both maps have especial merits, but the Englishman's, from being the work of an amateur, is the more remarkable of

* All of the Swiss maps are remarkably cheap. The sheets of the great map in 546 sheets will be sold at an uniform price of one franc each. The price of the Carte Dufour (which measures 3·50 metres wide by 2·40 metres high) was reduced about three years ago, by order of the Federal Council, from 100 to 40 francs, in order that it might be available for persons of small means. The whole of these maps can be procured from the bookseller Dalp, of Berne, who is the agent appointed for their sale.

* Another proof of the rarity of travellers is found in the ignorance of the natives of all kinds of money except their own, and the traveller should well supply himself with napoleons and francs, to avoid loss by exchange.

† I do not of course in this remark include the Swiss portion of the range, nor the basin of the Mer de Glace. That renowned glacier and its tributaries were well surveyed by the late Prof. J. D. Forbes in the years 1842-50, and the resulting map, which was published in 1855, was, I believe, drawn on stone by Dr. Augustus Petermann himself.

‡ Under the title of "Massif du Mont Blanc, extrait des minutes de la carte de France, lévé par M. Mieulet, Capitaine d'Etat Major."

the two, and notably illustrates how much a single unaided person may accomplish who makes his work a labour of love.

The condition of the Eastern Alps is even less satisfactory than that of the western part of the chain. The great French map will, doubtless, be completed sooner or later, and when it is finished the Western Alps will be fairly, although only fairly, represented. There is no immediate prospect of an equally perfect map being produced of the Eastern Alps. The map of Lombardo-Venetia, in forty-two sheets, on the scale of $\frac{1}{86400}$, is the most important one which touches these districts; and it is as much inferior to the great French map as the latter is to the Carte Dufour. Those who are intimately acquainted with these regions point to its too great generalisation of details and to its want of character, and observe that it (like other maps published at Vienna), although meritorious for its day, is now behind the times. Sundry amateurs have done good work in recent years in correcting or laying down afresh several of the *massifs* of the Eastern Alps, and amongst these individuals none are more worthy of mention than Mr. Tuckett and Lieutenant Payer. In the summer of 1864, Mr. Tuckett, of Bristol, devoted some time to the exploration of the Orteler group, and subsequently published a paper in vol. i. of the *Alpine Journal*, entitled "Contributions to the Topography of the Orteler and Lombard Alps:" This paper was accompanied by numerous outline sketches, and by a map. The latter, although roughly executed, gave, it is believed, for the first time with some approach to accuracy the positions and forms of the glaciers on the south side of the chain throughout the length of Val di Zebru, with the basins of the Vitelli and Nagler glaciers, and the lower portions of those of Sulden and Forno. All these were more or less incorrectly laid down (when represented at all) or vaguely indicated on the Government Maps. Further topographical corrections in connection with the Southern Orteler Alps (the result of visits in subsequent years) were recorded by Mr. Tuckett in the 2nd vol. of the *Alpine Journal*. With the labours of Lieutenant Payer the readers of this journal are already acquainted.*

Of the Alps of Piedmont there is no map in existence upon which dependence can be placed. A survey is said to be in progress, which will be eventually worked out upon a mammoth scale, and this will afterwards be adopted as the basis for a reduction of more moderate size. Many years must elapse before either of these maps can be produced, and in the meanwhile the old Sardinian Government map will be almost the sole authority. The shortcomings of this map are notorious, and one wonders at the rare ability of the draughtsmen who were employed upon it in projecting mountains which do not exist. The case of Mont Tseran is one of the most flagrant instances, but others could be quoted scarcely less audacious. Mont Tseran is laid down on sheet thirty-seven of the Sardinian map upon the northern side of the valley of the Arc, not far from the source of the river, and is credited with an altitude of 4,045 metres. There is no important mountain upon the spot which it is supposed to occupy, and Mont Tseran may be considered to be absolutely mythical. The late Mr. Cowell demonstrated that the peaks in this neighbourhood do not anywhere approach the height of 4,045 metres,† and those who cross the Mont Cenis Pass by the old road can easily satisfy themselves that no great mountain occupies the ground whereupon Mont Tseran was located by the Sardinian surveyors.

Several amateurs have endeavoured to reduce the Piedmontese Alps to a little order. Mr. Reilly (whose name has already been mentioned in connection with the chain of Mont Blanc) carried on a survey of the southern branches of the central Pennines in the years 1865-6, and afterwards projected his work upon the scale of $\frac{1}{100000}$. His map was published at the expense of the Alpine Club, and it is, I believe, the only one which at all fairly represents the southern side of Monte Rosa, the valleys of Valpelline, Barthelemy, and Tournanche, and the ranges which divide those valleys. Mr. R. C. Nichols has devoted several seasons to clearing up the topography of the Graians, and has from time to time communicated papers to the "Alpine Journal," some of which are illustrated by maps. But the full extent of his labours will not be known until a map is published, about which I have now a few words to say.

Some six or seven years ago the want of a general map of the Alps was a topic of conversation amongst those who habitually frequent those mountains, and ultimately a committee of the Alpine Club was appointed to superintend the production of a new map which was intended to rival the Carte Dufour in accuracy, and to comprehend the entire chain. The preliminary investigations quickly discovered that the plan must be modified, on account of lack of data; and it was at length determined to limit the scheme to the Central Alps, to the exclusion of the most eastern and western ones. Mr. William Longman, the eminent publisher, accepted the financial responsibilities, and Mr. Nichols was appointed editor.

This map will be in four large sheets on the scale of $\frac{1}{250000}$, and is being engraved on steel. It is now in course of production at the geographical establishment of Mr. Stanford, and it promises to be one of the most minutely and beautifully engraved maps ever published in this or in any other country. Its sheets are somewhat larger than those of the Swiss map on the scale of $\frac{1}{250000}$ and it does not extend quite so far to the north as the Swiss map, but in the south it embraces the important groups of the Graian Alps to the south of the Valley of Aosta, which include the Valleys of Locana, Cogne, Savaranche, Rhêmes, Grisanche, and the Tsère, with their peaks Tour de St. Pierre, Grivola, Grand Paradis, Grand Apparei, Aig. de la Sassière, Mont Pourri, and the Ruitor. All of these valleys and mountains are not included in the Swiss map. In the west the boundaries of the two maps are identical, but in the east the English one extends 10 kilometres beyond Landeck, thus taking in the Orteler group, the Zufallspitze, the Adamello and Presanella (all of which mountains will be just without the range of the Swiss map), but stopping short of the Oetzthal group, and thus excluding a great part of the Tyrol, the Bavarian Alps, and everything beyond. The map is expected to be completed in about two years, but it is not at the present time sufficiently far advanced to permit of an elaborate criticism. I believe, however, that it will be found to be little or not at all inferior to the Swiss maps in finish of engraving, in its relief, and in its accuracy, but will hardly be so clear as they are, in consequence of the introduction of details which would have been sufficient for a map of four times its scale. Still its appearance will be welcome to those who travel amongst or who are interested in the Alps, and it is to be hoped that the scheme as at first propounded will one day be carried out to its fullest extent.

In the foregoing rapid survey of maps of the Alps it has only been possible just to glance at some of the principal ones; but this glance has, I trust, enabled the reader to understand that an unlimited amount of work remains to be accomplished before the Alps can be said to be thoroughly explored, and that a splendid field still remains open for the employment of superfluous energy of men who desire to distinguish themselves. The efforts of individuals are scarcely perceptible upon so vast an extent of country; but a body of zealous observers, spread over its various districts, might break the neck of the work in a few years, and render it possible to produce for the first time a map of the entire Alps upon a uniform scale.

EDWARD WHYMPER

* Papers have appeared from time to time upon Lieut. Payer's work in the pages of Petermann's "Mittheilungen."

*EVANS'S STONE IMPLEMENTS OF GREAT BRITAIN**

WHEN Shakespeare represented his philosophical Duke, as finding "sermons in stones," and "books in the running brooks," he was but unconsciously exhibiting the prophetic faculty which has been attributed to all true poets. He could hardly have foreseen that his pretty yet fanciful conceit would one day be found to be sober earnest. But so it is; we have here a goodly volume of more than six hundred pages, illustrated by nearly as many excellent woodcuts, discoursing learnedly of nothing save stones and streams, and finding in them sermons of great and, to many readers, novel interest.

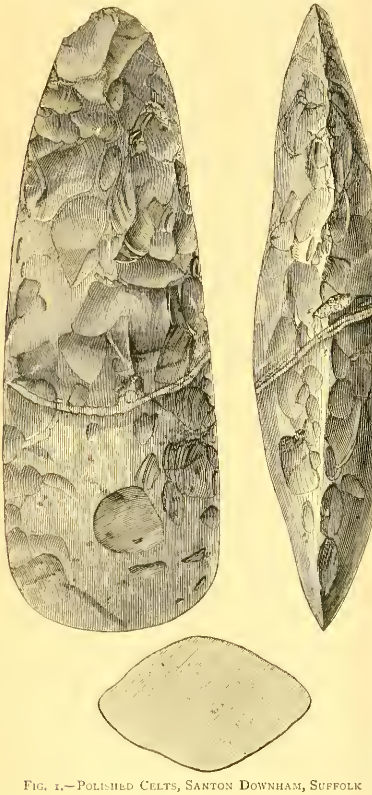

FIG. 1.—POLISHED CELTS, SANTON DOWNHAM, SUFFOLK

It might have been supposed, when Mr. Evans had published his well-known work on "The Coins of the Ancient Britons," that he had gone back as far as possible in the history of our land and nation; but in archæological as in other sciences, there is in the lowest known depth one lower still remaining to be fathomed; every chamber opened to the light discloses others lying beyond it. From a people who had no literature, or none of which they have left any trace beyond the rude characters inscribed on their rude coins, we are now carried back to tribes and races which possessed neither coins nor letters; people who have left us neither their sepulchres nor their ashes, nor indeed any trace of their existence, save the rude triangular or subtriangular fragments of worked stone which served them for tools or weapons; and even these are usually found buried beneath the wreck and ruin, it may be, of continents or islands which have long since been worn and wasted away.

The publication of this work is remarkable as an evidence of the quickened pace which characterises scientific research in our days. Palæontology and Geology, vigorous and flourishing as they are, are still hardly "out of their 'teens;" but Prehistoric Archæology has made comparatively more rapid progress than either. Not more than fourteen years have passed since the discoveries made by Boucher de Perthes of flint implements in the gravel beds of Abbeville and Amiens, although at that time discredited and disparaged by the geologists of his own country, were confirmed and supplemented by Mr. Prestwich and Mr. Evans. Previously to that time these objects had attracted but little notice; the things were "neither rich nor rare;" men looked at them and wondered, and then forgot them, just as before William Smith's time they gazed with a profitless curiosity on fossil shells and bones, and thought with Dr. Martin Lister, that they might be "the efforts of some plastic power, in the earth, being the regular workings of Nature, whereby she sometimes seems to sport and play, and make little flourishes and imitations of things, to set off and embellish her more useful structures."

FIG. 2.—AXE-HAMMER, THAMES, LONDON

But since the discoveries in the Somme Valley were recognised, a flood of light has been shed upon the subject. These dry bones live, and these rude stones are found to be useful, indeed indispensable, materials for building up the earliest history of the human race. The *savans* of every country in Europe have hastened to take part in an inquiry so novel and so interesting; many volumes of memoirs have been written; our French neighbours, with their usual vivacity, have established a journal devoted to Prehistoric Archæology, as well as an annual *Congrès;* and these researches having been for several years conducted by so many able and eager observers, we need not wonder that Mr. Evans, having studied the whole bibliography of the subject both ancient and modern, and explored every considerable museum or collection, is now enabled to produce this Encyclopædia of the new-born science, which for want of a better word may, perhaps, be called Petrology or Petro-tomology. He has introduced us into the workshops and armouries of our most remote predecessors, it may be of our ancestors, as they existed not at any particular epoch, but in all probability through a long succession of ages; and he has shown us so clearly what were their weapons and tools, of which any vestiges remain, and how they were made and used; and has correlated them so accurately, as far as might be, with similar objects found in all quarters of the globe, as well as with those described by classical writers, or in use by modern savages, that in reading his work we know not which most to admire, the industry shown in the collection and examination of such a vast amount of material, or the skill with which the informa-

* "The Ancient Stone Implements, Weapons, and Ornaments of Great Britain." By John Evans, F.R.S., F.S.A. (London: Longmans and Co., 1872.)

tion thus obtained has been methodised and arranged. The book completely exhausts the subject, and will long continue to serve as a perfect manual for the collector, as well as furnishing most useful materials for archæologists and anthropologists.

Those who are not already somewhat versed in this science will be astonished to learn the infinite variety of uses to which the apparently stubborn and unmanageable rock called flint has been converted. We may, perhaps, doubt if in the very earliest ages it was used for purposes of warfare, and we prefer to give our progenitors the benefit of that doubt, and to believe that those were "golden ages"—times of primitive piety and peace; and that it was only for purposes of husbandry, and the chase, and domestic use that they worked up the materials found in their plains and valleys. Thus, we find descriptions of celts, or axes for felling trees, or hewing canoes, hoes, threshing machines—as now used in the East—or

FIG. 3.—ARROW-HEAD, ISLE OF SKYE

perhaps harrows, scrapers for preparing skins, arrows for birds or other "small deer," knives, gouges, saws, mullers or pounding stones, chisels, hammer axes or picks, and polishing or grinding stones, of which there must have been great need; nor were the women of the period left destitute of their share of the stony spoil; for we find in these pages descriptions and figures of rings, armlets, amulets, spindle whorls, pestles, and, in the cave deposits, needles of bone of admirable workmanship, which might have been, and probably were, drilled by flint flakes.

As these primitive people have left us no record of their progress in arts and manufactures, and the material evidences bearing on the subject are found in a very confused and dislocated condition, it is a work of no small labour to classify and arrange them in order of date, or rather of sequence, and thus none but a rough and wide scheme of classification is possible. The Danish and French authors, as well as many of our own, usually divide the stone implement period into two principal stages only, the Palæolithic and Neolithic—unpolished and polished; placing them both before what has been called the Bronze age. This arrangement, however, although found convenient for popular use, and in that sense adopted by Mr. Evans, can hardly be regarded as scientifically accurate; as he has himself observed, there are blanks in the chronology of stone implements, which it is hard to fill up. The classification may be, and indeed is, too wide in one respect, and too limited in another. Whilst, on the

FIG. 4.—URQUHART

one hand, the drift and the cave implement periods, which are usually bracketed together as Palæolithic, are characterised by very various conditions, both palæontological and geological, and, indeed, technological also—conditions which may indicate their separation by a vast interval of time; so, on the other hand, as Mr. Evans has shown at the close of the fourth chapter, some of the unpolished stones, chipped or rough hewn celts, were probably of a date not earlier than some that were ground and polished; and, in Great Britain, at least, there are not wanting indications that the use of bronze was coeval with the polished stone period, if not, indeed, with one or two exceptions (which were probably imports) anterior to it.

One of the most perplexing questions suggested by the discovery of the drift implements relates to the means by which they came into their present position. They are often met with at a depth of twenty or even thirty feet,

FIG. 5.—ABERDEENSHIRE

usually at or near the base of thick beds of coarse flint gravel, which in its turn is overlain by masses, more or less thick, of brick-earth or loess. Occasionally, and indeed not rarely, they occur entirely beneath the gravels, and on the surface of the subjacent rock, whatever it may chance to be. Mr. Evans deals with them merely as constituent portions of the beds of sand, gravel, and clay, in which they occur, and so indeed they now are, but they are something more. Although of the drift, drifty, each has its own separate history; for each has been held and fashioned by hands guided by an intelligent will, and thus

we are led irresistibly to inquire when, and why, and how did they come where we now see them, and why are they never found on the surface, nor under any other conditions?

To a certain extent this inquiry is involved in the far larger question of the forces by means of which the superficial gravels, of which the implements are as it were but the accidents, became dispersed—a subject which does not necessarily come within the scope of a work designed to be technological rather than geological. Mr. Evans has, however, very judiciously devoted one of his chapters to it; and as it is one of great interest, and is still involved in much obscurity, we may gladly welcome any attempt to deal with it, especially by one who has given so much attention to its investigation.

It was the opinion of the late Dr. Buckland, an opinion which was concurred in by Greenough, Conybeare, and other able writers of their time, that the general dispersion of gravel, sand, and loam, over hills and elevated plains, as well as valleys, was the result of a universal deluge, which is described as transient, simultaneous, and of a date not very remote; that the existing system of valleys was mainly due to the same cause, and that thus both valleys and gravels preceded our present river systems. Cuvier, and the French geologists generally, have held the same opinion, but of late years it seems to have been altogether discredited by English authors, with perhaps the exception of the late Sir Roderick Murchison. We may well entertain doubts as to the occurrence of a deluge that should be both universal and simultaneous; and it is probable that it is chiefly on that account that Dr. Buckland's theory has met with so little favour. Still, although we may be unable to adopt his views in their entirety, his statements as to the diluvial characters of the English drifts seem entitled to some further consideration before they are set aside altogether, and on this account it is fortunate that the recent discoveries of flint implements have excited so much interest in the gravels in question as to induce Mr. Evans to devote no inconsiderable portion of his work to the history and antiquity of the River drift.

In the last chapter he has adduced an elaborate argument in favour of the belief in fluviatile transport as opposed to diluvial, by showing first hypothetically the possibility that "deposits now occupying the summits of hills have originally been formed in and about river beds," and then, by reference to the actual phenomena, the probability that the implement-bearing beds were thus formed. No one can doubt, upon the hypothesis here stated, that rivers may have possessed at one time a far greater power of excavating and deepening their channels than now; but then the author is obliged to assume the prevalence of several conditions, and notably a far more rigorous climate, and a greater amount of rainfall; conditions as to which we have but little evidence, and some of that is of a doubtful tendency. If, as is now supposed, the hippopotamus and elephant and rhinoceros remained here all the winter, they would have fared but badly, had the climate been as severe as is supposed.

But passing by these topics as not bearing very immediately upon the question of transport, it cannot be doubted that submergence, by means of diluvial action, is quite possible, since we have many instances of it within the historical period, and some indeed within the last few years; and both modes of transport being alike possible, the probabilities of the case have alone to be considered; and, notwithstanding the various reasons so ably stated by Mr. Evans, it does not seem that there are sufficient grounds for rejecting Dr. Buckland's theory, and there are besides some inferences to be drawn from the position of the implements which, so far as they are concerned, are at variance with the theory of fluviatile transport. For instance, when met with in valleys, it appears that the implements are not found along the whole course of those valleys, as well where flint gravels are wanting, as where they abound, as would have been the case had they been carried down promiscuously by the streams from time to time; but, only in certain limited areas, and then usually in large numbers, and at about the same levels; and further, that in several of these deposits the implements are distinguished from those of neighbouring deposits by some slight difference in form. From these indications it may be inferred that they were made and left at or near the spots on which they are found, and afterwards covered up, and occasionally displaced, by the masses of drifted material which now overlie them; and this seems the more probable, when it is seen that some of them were formed from stones of the same kind as those composing the beds in which they rest, and that some of these appear to have lain exposed upon the surface for long periods before they were worked.

If, indeed, it had happened that these things had never been found elsewhere than in river valleys, the conclusions arrived at by Mr. Evans would have been irresistible, but so far from this being the case, it is certain that these implement-bearing gravels are occasionally found on the extreme margin of sea cliffs, or isolated hills on the verge of far-stretching plains—situations to which no river flowing in the same channels, and draining the same areas as now, could have carried them.

Mr. Evans has noticed several of these deposits as met with at Bournemouth, the Reculvers, and the Foreland cliffs in the Isle of Wight (to these probably should be added Southampton, and Brandon Down, and some others); and he has also alluded to the remarkable discovery in the Madras Presidency of implements of quartzite of true drift type, found on the cliffs at an elevation of three hundred feet above the sea, in a bed of ferruginous clay which forms the coast line for several hundred miles, and is intersected at right angles at various intervals, by the rivers of the country in making their way to the sea.

In all these cases all traces of the ancient rivers, if indeed they ever existed, have been entirely effaced; neither channels, nor outlets, nor adequate water-sheds, nor a single land or river shell, remaining to testify of them; and not only so, but we find many deposits of quaternary gravel (which Mr. Evans justly concludes to be of the same geological period as those of the implements, and to owe their existence and position to the same causes) on hills which could not have been reached by modern rivers. The whole country would have been a vast lake before such heights could have been submerged; and under such circumstances it may be fairly assumed that the same forces, whatever they were, that covered the hill-tops, may have partially filled up the valleys; the presence of gravel may suggest, but cannot prove, that the river brought it, however much it may have re-arranged and sorted it; both valley and gravel may have had an existence before the river began its course. We have many valleys and gravels without rivers, and rivers without gravels; they can very well exist apart, and, doubtless, have often done so.

(*To be continued.*)

THE HUNTERIAN MUSEUM *

ONE of the most interesting features in connection with the annual election of Fellows into the Council of the Royal College of Surgeons, is the exhibition of additions about to be made to the Museum, and which have accrued since the last meeting. Prof. Flower, the Conservator, states in his Report that in the pathological collection eighty-eight additions have been made, against sixty-two during the past year, and that the microscopical characters of all recent specimens sent to the College, and thought worthy of preservation, had been carefully described and delineated by Mr. Goodhart, the Pathological

* From the *Medical Times and Gazette*.

Assistant, on whose great zeal a well-deserved eulogium is expressed.

Although but very little has been expended in the purchase of osteological specimens, the additions are of considerable importance. Amongst those specially mentioned is the skeleton of an extremely rare whale, the *Berardius Arnuxii*, purchased for the Museum by Prof. Wilson, F.R.S. The series illustrating the structural peculiarities of the human race has received two very valuable additions in skeletons of both sexes of the extinct aboriginals of Tasmania, presented by Mr. M. Allport, of Hobart Town. Both have been articulated. The male is in exceedingly good preservation; that of the female is unfortunately less complete, but still presents many interesting features.

The liberality with which the Smithsonian Institution of Washington is conducted has been shown by various important additions to the museum in former years, but especially during the present, in a series of skulls and skeletons of North American mammals, several of which were new to the collection. The College has reciprocated this liberality by presenting a set of casts of the interior of crania of various races of men and animals, and some duplicates.

Another important addition is the skeleton of an adult male Porbeagle shark, about eight feet long. This is valuable, from the great difficulties which have usually attended the attempts made to preserve the osseous system of cartilaginous fish. These difficulties have been overcome by the great skill of Mr. James Flower, the experienced articulator to the College. This will be found a very instructive specimen to students.

In the dermatological collection Mr. Erasmus Wilson still shows the deep interest he takes in it by presenting twenty-five beautifully executed models; and M. Voillemier, Surgeon to the Hôtel-Dieu, Paris, has presented two, representing elephantiasis of the scrotum, with its cure resulting from operation.

Amongst the contributors are Profs. Gervais, of Paris, and Peters, of Berlin; Sir William Fergusson, who gives a great number of preparations; Sir James Paget, Messrs. Hilton, Holden, Busk, Clark, Gay, Curling, Wilson, Jackson, the Zoological Society, and the Smithsonian Institution. Mr. Kiernan, a late member of the Council, has presented the whole of his collection.

During the day of election the theatre, where these additions are displayed, was visited by a large number of the Fellows. It remains open for the inspection of the members and their friends for a few days.

NOTES

We reprint in another column a document which will be read with the greatest indignation by scientific men in every part of the world, and with shame by all Englishmen. We refer to the remonstrance presented to the Treasury by eleven of our most distinguished scientific men against the treatment which the eminent Superintendent of the Royal Gardens at Kew has received at the hands of his official superior, the Chief Commissioner of the Board of Works. Though we might take exception to some of the arguments brought forward by the memorialists, yet there can be but one opinion that the systematic discourtesy and want of consideration with which Dr. Hooker has been treated is entirely incompatible with the efficient conduct of the department of the public service with which he has been entrusted, and deserves the most searching inquiry on the part of the Government.

Prof. Agassiz's Second Report to the United States Coast Survey of the scientific results of the *Hassler* expedition, a portion of which we reprint this week, is one of the most important contributions to scientific knowledge which has appeared for some time. His remarks on the glaciation of South America, and the origin of the so-called "raised beaches" of Patagonia, are especially valuable.

The short communication from Dr. Anton Dohrn on the present position of the Zoological Station at Naples will be read with great interest. The mode in which the Italian Government is assisting this important undertaking forms an instructive contrast to the action, or rather want of action, of our own Government in the matter of the Tides Committee to which we recently alluded. When will Englishmen be able to compare with any other feeling than that of shame the policy of their own Government with that of any other civilised nation of the world in all matters relating to Science?

According to the constitution of the Institution of Civil Engineers, it consists of three classes, viz., Members, Associates, and Honorary Members, with a class of Students attached. Of these several grades there were on the books on the 1st inst. 756, 1,127, 16, and 243, respectively, making in the aggregate 2,142. The increase in the last three months in the different classes has been 11, 36, 2, and 9, representing an effective addition of 58.

We understand that Prof. Palmieri's account of the late eruption of Vesuvius is being printed at Berlin by Link and Reinke, and will be published in several languages. It will be illustrated by five lithographs taken from photographs.

M. Delaunay, director of the National Observatory at Paris, has taken possession of the Observatory at Montsouris.

The Society of Sciences of Haarlem has named the following subjects for competition for essays, to be sent in before January 1, 1874:—1. A study in detail and exhaustively of the influence which chemical and physical modifications of the solvent exercise on the form of carbonate of lime when deposited from aqueous solutions. 2. A critical examination of the various hypotheses on the origin of polar auroræ, and the relations between the polar auroræ and other natural phenomena. 3. On the changes which stone-fruits undergo during their development. 4. On a satisfactory means of determining the temperature, the degree of humidity, and the density of the atmospheric air at a considerable height above the surface of the earth. Also before Jan. 1, 1875:—An exhaustive study of some Linnean species, chosen from those which present more or less divergent forms. The prize for each of these Essays consists, at the choice of the author, of the ordinary gold medal of the Society, or a sum of 150 florins, with an additional 150 florins if thought worthy. The memoirs may be written in Dutch, French, Latin, English, Italian, or German.

Mr. L. H. Courtney, M.A., Fellow of St. John's College, Cambridge, has been appointed Professor of Political Economy at University College, London, in the room of Prof. Cairns. Two Slade Scholarships in Fine Arts, tenable for three years, have been conferred at the same Institution on Miss E. M. Wild and Miss B. A. Spencer.

At a meeting of the Council held on July 6, the Associateship of the Royal School of Mines was conferred on the following gentlemen:—Mining and Metallurgical Divisions—W. Charlton, O. Pegler. Mining and Geological Division—G. M. Dawson. Mining Division—E. Dillon. Metallurgical Division—F. W. Harrold, J. H. Huxley, O. F. Mondy, A. G. Phillips. The following awards were made:—First year students—The two Royal Scholarships of 15*l.* each to Mr. S. A. Hill and Mr. J. Taylor. Second year students—H.R.H. "The Duke of Cornwall's" Scholarship, 30*l.* for two years, to Mr. Edgar Jackson, and the Royal Scholarship of 25*l.* to Mr. C. Law, and the Murchison Medal and Prize of Books to Mr. S. W. Davies. Third year students—The Edward Forbes Medal and Prize of Books in Natural History and Palæontology to Mr. G. M.

Dawson. The De la Beche Medal and Prize of Books in Mining to Mr. W. Charlton.

THE forty-fifth annual session of the German Society of Naturalists and Physicians will be held in Leipzig next month. The meetings will commence on Monday, August 12, and end on Sunday, August 18. The secretaries announce that visitors from foreign parts will be welcome.

THE Vicar of Folkestone has written to the *Times* stating that the memorial west window which it is proposed to place in the parish church to commemorate Harvey will consist of eight subjects from Our Lord's Miracles of Healing, and that underneath it will be recorded on a brass Harvey's great discovery. This project is, we believe, entirely apart from that set on foot by the committee of which Dr. Bence Jones is treasurer, whose object it is to erect a statue to Harvey at Folkestone.

THE death of Rev. M. A. Curtis, of Hillsborough, North Carolina, which took place in April last, must be considered as among the most serious losses that natural history in the United States has experienced for some time. The attention of Mr. Curtis was directed especially to the fungi, although he was more or less familiar with all the plants of the Southern States. In his special department, however, he stood at the head of American botanists, occupying the position in this country of Mr. Berkeley, his correspondent, in England. Mr. Curtis prepared the report upon the fungi collected by the United States exploring expeditions, and has contributed various articles to the literature of this science. Among other works nearly ready for the press was one upon the edible fungi of the United States, illustrated by figures and descriptions of some sixty species. The qualities of most of these he had personally tested by experiment, particularly during the late war, when the food question was for some time a matter of serious moment.

A LATE number of the *Chemical News* contains a suggestion for the formation of an "Association of Manufacturing Chemists," which might hold annual meetings after the fashion of the Iron and Steel Institute, at which topics would be discussed connected with the various important branches of chemical manufacture. It is obvious that meetings of this kind, and papers read to such a body, with the discussion which would result therefrom, might be in the highest degree beneficial to a large body of men engaged in a manufacture requiring a large amount of scientific knowledge and acquaintance with technical details.

A WRITER in the *Food Journal* points out the advantages, to the Central Authority and to the Government, of a National Registration of Sickness. As a basis for sanitary legislation, as an indication for interference on the part of the Central Authority in local sanitary affairs, as a test of the health conditions of the country, as well as of its separate parts, no mass of information could bear comparison with that which would result from a well ordered registration of diseases.

Harper's Weekly records the safe arrival of Mr. Henry W. Elliott at the island of St. Paul, Behring Sea, on April 28. He left Washington last March under an appointment from the Treasury Department, as an assistant of Captain Bryant in looking after the interest of the United States in connection with the fur seals on the Pribylow Islands. Mr. Elliott expects to spend some time at St. Paul, and to devote much attention to the study of the islands, and in collecting apecimens of their natural history. Wielding a ready pencil, he also proposes to make sketches from life of the fur seal, the walrus, sea-lion, &c., so as to give us a better idea of their general appearance than we can gather from the stuffed caricatures in public museums.

IN addition to Prof. Agassiz's Report, given in another column, several communications have been received from gentlemen connected with the *Hassler* expedition, all bearing testimony to the zeal with which the operations of the party have been prosecuted. Under date of March 12 it was reported that, after leaving Montevideo on Feb. 20, the dredging work was carried on with due diligence and with very interesting results, numerous radiates of great beauty, many of them undoubtedly of new species, being brought to light. Among the objects of particular interest were the floating stems of the giant kelp of the South Pacific, *Macrocystis*, which sometimes attains the length of 500 to 1,000 feet, the stems being a foot in diameter, and resembling trees in magnitude. The vessel entered the Straits of Magellan on March 13, and passing through, arrived at Talcahuana, in Chili, on April 11, where it was expected to remain several days for repairs and provisions. Prof. and Mrs. Agassiz proposed to spend the interval in a visit to Santiago and Valparaiso, while Count Pourtales and his assistants were to make a line of deep-sea soundings and dredgings from Talcahuana to the island of Juan Fernandez and back to Valparaiso.

THE United States Coast Survey has received advices from Mr. William H. Dall as late as May 5. At that time he was at Illulluk, Oonalaska, the head-quarters of his explorations. He has been diligently engaged through the winter in carrying out the objects of his mission connected with the geography and hydrography of the Aleutian Islands, as well as the weather would permit, a constant succession of storms of extreme violence having interfered greatly with his work. The lowest temperature recorded by him during the past winter was 13°, the average from October to March being 33°. Mr. Dall has devoted such time as he could spare while detained in port, to making collections of natural history specimens, and has obtained quite a number of forms, some of which he considers new to science.

A PROPOSITION has been entertained to tunnel under the Strait of Canso, between Nova Scotia and Cape Breton, where the strait is only two and a half miles wide, for the purpose of connecting the island of Cape Breton with the mainland. The cost is estimated at 2,500,000 dols. This idea is connected with a proposition to run a line of steamers from Glasgow, or other British port, to Louisburg, the most easterly point of Cape Breton.

THE *Panama Star and Herald* records the first arrival on April 2, at Panama, on its annual eastern migration, of the beautiful sphinx moth (*Urania leilus*). The immense flights of this moth, and the extreme regularity of their recurrence year by year, have repeatedly been dwelt upon by the *Star*, and much interest has been excited as to its starting-place and ultimate destination.

THE Report of the Winchester and Hampshire Scientific and Literary Society for 1870-71, congratulates the members of the Society on the successful results of the second year of its existence. Though no important discoveries were due to the labour of the Society during the year, and the weather was very unfavourable for out-of-door work, steady progress was made in some departments, especially in the list of the flora of the neighbourhood, which now includes nearly 700 species. Abstracts of papers on various branches of science, read at the meetings of the Society, are printed in the Report.

THE Malvern, Bath, and Woolhope Field Clubs met for a joint excursion on May 17, an account of which is printed in a separate form, and to it is appended the Report of the Annual Meeting of the Malvern Field Club, with the Address of its President, Mr. Edwin Lees.

A NEW journal has been recently started in New York called "Handicraft: a popular Journal of Progress of the Industrial Arts, designed for workers and thinkers." The number on our table contains papers and short paragraphs, on inventions in the mechanical arts, illustrated with woodcuts, with notices of books, &c.

MR. AYRTON AND DR. HOOKER

THE comments which have been made by several London journals upon the circumstances referred to in the subjoined memorial, seem, in the interest of all persons concerned, to render its publication in its entirety desirable. We cannot doubt that any delay which has occurred, or may occur, in the delivery of a reply to the memorialists, is due to the desire of the Prime Minister to deal with the important question at issue in a manner which, while it is not inconsistent with the interests of the public service, is not incompatible with a due regard for the interests of Science, and for fair dealing towards a very eminent scientific man.

TO THE RIGHT HON. W. E. GLADSTONE,

First Lord of the Treasury, &c. &c.

We, the undersigned, deeply interested in the condition of English science, and viewing with special concern the treatment which the eminent Director of the botanical establishment at Kew has systematically received at the hands of Mr. Ayrton since his appointment to the office of First Commissioner of Works, do most respectfully beg your attention to the following statements and observations.

In the year 1840 the private Botanic Gardens of Kew, which had previously been in the possession of the Royal Family, were handed over by the Queen to the Government.

A commission then appointed to report on their condition recommended that they should be enlarged and maintained as a national scientific establishment, which should form a centre of reception for the useful products of the vegetable kingdom, a centre of reference and distribution for England, India, and the colonies, and a means of augmenting the rational pleasure, increasing the knowledge, and refining the taste of the English public.

The late Sir William Hooker was at that time Prof. of Botany in the University of Glasgow. The founding of an establishment like that contemplated at Kew harmonised so completely with his scientific tastes and power of organisation, that, at a sacrifice of more than half his income, he offered to undertake the superintendence of Kew Gardens. His offer was accepted, and he was appointed Director of Kew, at a salary of 300*l*. a year.

Sir William Hooker was at that time the possessor of an excellent private herbarium and of a scientific library, both of which were wanting at Kew. To provide house-room for these an additional 200*l*. was granted by the Government. No allowance, however, was made for the maintenance or increase of either the herbarium or the library. The expense of both fell upon the director.

During his residence in Glasgow, the excellence of his collections had attracted to the house of Sir William Hooker various active investigators, the number of which increased materially after his arrival at Kew. Fourteen rooms of the house he occupied were devoted to his herbarium, which for twelve years was the resort of the scientific botanists of Europe. Unaided by the Government, save to the extent above mentioned, Sir William Hooker devoted his private means to the purchase of new books and specimens, and opened a correspondence with botanists of all lands. He thus made his house the most extensive botanical laboratory in this country, and the most important centre of reference regarding systematic, economic, and descriptive botany, as illustrated by his herbarium.

The gardens expanded equally under his vigorous and enlightened supervision; in ten years after his appointment they became the first in the world.

For twenty-five years he had been collecting textile fabrics, drugs, gums, dyes, and other products to illustrate the structure, uses, and physiognomy of plants. With these collections, made at his private cost, Sir William Hooker founded in Kew Gardens the first museum of the kind that had ever been established. Of such museums there are now three at Kew. They contain upwards of 50,000 named objects of scientific and economic interest, views of tropical vegetation, and maps illustrating the distribution of plants over the globe. These museums constitute concrete courses of instruction, unrivalled in concentration and completeness; and the public interest in them is proved by the number of persons who avail themselves of the stores of information thus provided.

The contributions of Sir William Hooker to these museums were his free gift to the country, for which he never received a farthing of remuneration.

In 1852 the director's salary, which had previously been raised to 600*l*. a year, was augmented to 800*l*., together with a house which had become vacant at the time. The herbarium was then lodged in a separate building, and immediately afterwards donations and legacies (some to the director, some to the Government of the day) poured into it. The labour of naming the collections of expeditions, and of drawing up botanical reports, became at length so excessive that the public need of the herbarium was still further recognised by the Government. The director had previously borne the expense both of assistance and maintenance; of these he was now relieved, though he still continued to bear the cost of books for his library and of new specimens of plants.

Without this personal devotion on the part of the director, the development of Kew would have been a simple impossibility. For five-and-twenty years his purchases were made and his collections elaborated at his own expense and risk, though they were constantly employed in the work of the country. Before his death, knowing that his son could not afford to be as regardless of pecuniary considerations as he had been himself, he gave directions to have his herbarium valued by competent persons and offered to the Government at the lowest valuation. On these terms the collections which had previously been devoted to the nation's use became the property of the nation itself.

This is a brief but sufficient statement of the relationship of Sir William Hooker to Kew Gardens. It shows him to have been their virtual creator.

The antecedents and achievements of the present Director of Kew may be thus sketched. In 1839 Dr. Joseph Hooker was appointed Assistant-Surgeon and Naturalist to the Antarctic Expedition, the most perilous, perhaps, that ever sailed from these shores, and the scientific results of which exceeded in importance those of any other naval exploring expedition of this century. During this voyage Dr. Hooker received from the Government the pay of his rank as a medical officer. His outfit, his books, his instruments, were provided by his father. The expenses of travelling and collecting ashore during his four years' voyage of circumnavigation were defrayed from the same source, though this work was done with the express object of enriching a public establishment.

On his return, he waved his claim to promotion in the navy, and devoted four additional years to the classification and publication of the results of the voyage. He also aided his father as an unpaid volunteer in the development of the scientific branches of the Kew establishment.

In 1847 Dr. Hooker was sent to India, to explore, in the interests of Kew, an unknown region of the Himalaya; and he was directed to proceed subsequently to Borneo, to report on its vegetable resources. His outfit, both for India and Borneo, which embraced a large collection of expensive instruments, cost the Government nothing. To cover all expenses incidental to his three years' travelling and collecting, including the cost of assistants and specimens, a sum of 1,200*l*. was received, while the real disbursements of Dr. Hooker during this time amounted to 2,200*l*. The difference was contributed by Sir William Hooker and his son, in the interest of the establishment to which they had consecrated their best energies.

On his return from India, Dr. Hooker again devoted himself to the work of aiding his father in the scientific development of Kew. He was also employed by the Admiralty, during the nine years from 1851 to 1860, in publishing the botanical discoveries of various naval and other voyages, from Captain Cook's downwards, to parts of the world visited by Dr. Hooker himself. For this service he received three years' pay as a medical officer in the Navy, together with a sum of 500*l*., which was accompanied by "the expression of their Lordships' approbation of the zeal, perseverance, and scientific ability displayed in bringing to a successful completion this great botanical work." For three years he was occupied with the arrangement and distribution of his Indian collections, and with the publication of his journals. To cover the expenses incidental to these labours, an allowance of 400*l*. a year was granted by the Government.

Besides the voyages and travels above adverted to, Dr. Hooker has made journeys to various parts of Europe, to Western Asia, and to North Africa. The expenses of these journeys, though they were made with the express object of adding to the interest and completeness of Kew, have been borne by himself, and the results given to the establishment of which he is director.

We place these data before you, not with a view of founding on them either censure or complaint. The labours of Dr. Hooker,

and the heavy drain upon his father's purse which his unexampled education as a botanist involved, constituted the discipline which made him the man he now is. But we think it highly desirable that you and England should know as much of his career as will enable you to decide whether its arbitrary interruption by your First Commissioner be creditable to the Government of this country.

In 1855, Sir William Hooker being then seventy years of age, Dr. Hooker was appointed his Assistant-Director, at a salary of 400*l.* a year, without a house; and from this time his share in the duties of the Garden were added to his more purely scientific ones. In 1858 his salary was increased to 500*l.* a year, with a house, and in 1865, on the death of his father, he succeeded to the Directorship without an assistant

The liberality of his father and his own self-denying life in the public service have, we think, been sufficiently illustrated. We will therefore ask permission to place before you only one additional specimen of his conduct. As regards the Floras of Asia, Africa, and America, the Herbarium at Kew had been long unrivalled. Europe, however, was but scantily represented. Three years ago, a collection embracing the very flora needed for the completion of Kew was offered for sale in Paris. At his own private cost, Dr. Hooker purchased this collection for 400*l.*, and presented it to the Kew Herbarium.

His income at Kew is 800*l.* a year, and here is one-half of it voluntarily devoted to the establishment which it had been the continual object of his father and himself to raise to the highest possible perfection. Had these things been known to the Parliament and public of England, the First Commissioner of Works would, we imagine, have hardly ventured to inflict upon the Director of Kew the unnecessary toil, worry, indignity, and irredeemable loss of time against which this memorial is a remonstrance.

Under the auspices of his father and himself, Kew Gardens have expanded from 15 to 300 acres. They have long held the foremost rank in Europe. In no particular does England stand more conspicuously superior to all other countries than in the possession of Kew. The establishment is not only without a rival, but there is no approach to rivalry as regards the extent, importance, or scientific results of its operations. Upwards of 130 volumes on all branches of botany, including a most important series of Colonial Floras, but excluding many weighty contributions to scientific societies and Journals, have been issued from Kew. To these are to be added guide-books and official papers. This vast literature has been produced and published through the efforts of the directors of Kew, for the most part at no expense whatever to the nation.

To these labours is to be added the correspondence of the directors with all parts of the world, a mere selection from which, now bound together at Kew, embraces some 40,000 letters addressed to the directors, and for the most part answered with their own hands.

Of the popularity of the Gardens, which has been attained without prejudice to their scientific use and reputation, it need only be stated that from 9,000 visitors in 1841, the numbers have risen to an average of nearly 600,000 a year. What they have done towards the elevation and refinement of the tastes and conduct of the working classes may be inferred from the fact that last Whit Monday 37,795 visitors entered and quitted the Gardens without a single case of drunkenness, riot, theft, or mischief of any kind being reported.

Since Dr. Hooker's accession the Gardens have been to a great extent remodelled, and the establishment wholly reorganised. A great saving in outlay has thus been effected, without any sacrifice of efficiency. During the ten years from 1863 to 1872 inclusive, the annual number of living plants sent from Kew to various parts of the world has been doubled, amounting on an average to eight or nine thousand annually. Of seeds ripened at Kew, or obtained by the director from various parts of the world, the annual average distributed amounts to about seven thousand.

Of the practical value of these labours, the introduction of the Cinchona plant into India, Ceylon, and Jamaica, the commercial success of which is established, constitutes one of many illustrations. The introduction of Ipecacuanha is another. This will be corroborated by Her Majesty's Secretaries of State for India and the Colonies. We would add, that there is scarcely a horticultural establishment at home or abroad which would not be willing to acknowledge its indebtedness to Kew.

In India upwards of thirty gardeners trained at Kew are now employed in forestry, cotton, tea, and cinchona plantations, Government gardens, &c., and a far greater number are usefully employed in other parts of the world.

By the joint efforts of the directors, a series of complete Floras of India and the Colonies was set on foot at Kew, of which those of the West Indies, all the Australian Colonies, New Zealand, Tropical Africa, the Cape Colonies, and British India are completed or in progress. These are standard works of inestimable value in the countries whose plants they describe, as well as to scientific travellers and institutions in Europe.

We have hitherto confined ourselves to a statement of Dr. Hooker's services in relation to Kew, and have said nothing of his labours in geology, meteorology, and other sciences, nor of his researches while Botanist of the Geological Survey. During his single year of office he contributed to the Records of the Survey two memoirs, which are to be regarded as landmarks in the history of fossil botany. In presenting the Royal medal to Dr. Hooker in 1854, the president of the Royal Society spoke of these memoirs as "one of the most important contributions ever made to fossil botany." We may add a reference to his adventurous explorations of the northern frontier of India, in regions never visited by a European before or since.

It is not likely that a man of these antecedents, accustomed to the respect which naturally follows merit of the most exalted kind, would in any way expose himself, and more especially in matters relating to the welfare of Kew, to the just censure of his official superiors. Until the advent of the present First Commissioner, he had never been the object of a censure, and was never interfered with in the practical discharge of his duties by the Board of Works. His proposals and suggestions were rightly scrutinised, and his estimates regulated by the opinions of the Board, but the current duties were left entirely to his conduct and supervision; the extension and improvement of the establishment being always the origination and work of the Director.

With this sketch of the early training of Dr. Hooker for his present post before you, you will be able to compare with it the early training of Mr. Ayrton for the position which, by your favour, he occupies as Dr. Hooker's master. You will be able to judge how far the First Commissioner is justified in treating the Director of Kew with personal contumely, and in rudely upsetting the arrangements which he had made with reference to the invaluable collections for which he is responsible, not to Mr. Ayrton alone, but to his conscience and his country.

Neither you, Sir, nor the English public have forgotten the speech of the First Commissioner on presenting himself for re-election at the Tower Hamlets, when he went out of his way to insult "architects, sculptors, and gardeners." That speech was a warning to every cultivated man who held office under the Board of Works, and it was, as you know, duly laid to heart by the Director of Kew. His desire to avoid all cause of offence was thus expressed in a letter addressed to yourself on August 31, 1871:—"Having regard to the tenor of the sentiments Mr. Ayrton is reported to have expressed in public on accepting office, I felt it incumbent on me to be especially circumspect in my conduct and demeanour under his rule."

Circumspection, under the circumstances, was of small avail, and one of Mr. Ayrton's first acts, after taking office, was to send a reprimand to Dr. Hooker. It was a new experience to the Director of Kew. During his thirty years of public service such a thing had never once occurred; indeed, the very reverse of it had always occurred, the respect due to intellectual eminence and moral worth having been always cheerfully accorded to Dr. Hooker by his official superiors. This first reprimand of his life was, moreover, not due to any fault of his, but arose entirely from the First Commissioner's own misconception.

The responsibility of the warming and ventilation of the plant-houses had, by special order, devolved upon the Director. After a searching inquiry, Dr. Hooker had been entrusted by a previous First Commissioner with the task of remodelling the heating apparatus throughout the establishment; and this led to the construction at Kew, in accordance with the Director's plans and estimates, of the most complete range of hot-houses for scientific purposes in existence. In 1871, however, he accidentally discovered that he had been superseded in the duty, without notice given or reason assigned. He wrote a respectful letter of inquiry to the First Commissioner, and received the short—we are persuaded you will agree with us in adding, insolent—intimation that he *had* been superseded, and would have "to govern himself accordingly."

He would, in our opinion, have been equally unfaithful to the

science of which he is a leader, and the public which he had so long served, if he had bowed in silence to this rebuke. He wrote a second letter of remonstrance to the First Commissioner, in which he expressed himself as follows: "The matter, therefore, stands thus: Several months ago I was, unknown to myself, deposed from the discharge of a function of great importance. I was left to hear this accidentally and, I have now to add, through one of my own subordinates.

"I do not for a moment question the First Commissioner's power to exercise arbitrary authority over the Director of Kew, but I do submit that there has been hitherto no plea whatever for such action as regards myself, and that the repetition of such acts, and the leaving me to be informed of them, *on each occasion*, by my subordinate, constitute a grievous injury to my official position, and tend to the subversion of all discipline in this department."

At this point, Sir, Dr. Hooker turned in the fullest confidence to you. He had undoubting trust in your will and power to protect both Kew and him from the arbitrary and, we would add, ignorant acts of the First Commissioner. He respectfully claimed the privilege of bringing the matter under the cognizance of the Right Honourable the First Lord of the Treasury.

You doubtless remember the letter addressed to you by Dr. Hooker on August 19, 1871. You could not fail to remark the reluctance with which he appealed to you, and his previous anxiety to take all possible measures to avert the necessity of such an appeal. "I cannot express to you, Sir," he writes, "the anxiety that this step costs me, nor how earnestly I have endeavoured, by suppressing all personal feelings, to conduct my duties here under Mr. Ayrton to his and to my own satisfaction.

"After upwards of thirty-two years spent in the public service at home and abroad without a suspicion of mistrust on the part of my many previous superiors, I have had since Mr. Ayrton's accession to submit to various arbitrary measures, which, though compromising my position and authority, have been concealed from myself and become known to my subordinates, through whom alone I have first been made cognizant of them."

From you, Sir, the Director of Kew received no direct reply to this communication; but by the First Commissioner he was requested to "furnish the dates and particulars of the conspicuous proofs of disregard to his office, and the particular occasions and facts with dates, of his being left to be informed through his subordinates of acts of arbitrary authority of the First Commissioner, and the dates and particulars of those acts."

To this challenge the Director of Kew replied by adducing five distinct acts of arbitrary interference, with their "dates," "proofs," and "particulars." * Among them was included what we have a right to call clandestine tampering with the subordinates at Kew. For example, the Curator of the Gardens was tempted by Mr. Ayrton, personally, to leave Kew by the offer of a higher position, involving authority over works at Kew; and he was requested by Mr. Ayrton to keep the fact from the knowledge of Dr. Hooker. To the loyalty of this man to a master whom he trusted and loved, the Director of Kew owes the discovery of proceedings which under any previous First Commissioner would have been impossible.

Your attention, Sir, was drawn to this reply in a letter addressed to you by the Director of Kew on the 31st of August, 1871. It is in every respect so excellent, and so sure to be appreciated by all who know the real meaning of scientific work, and the baneful effect upon such work of this harassing conflict with your First Commissioner, that we do not hesitate to reproduce it here *in extenso*.

"Royal Kew Gardens, August 31, 1871

"Sir,—I beg most respectfully to submit copies of my further correspondence with the Right Honourable the First Commissioner of Her Majesty's Works, &c.

"The acts detailed in the accompanying letter are, I believe, correctly described. I trust that I do not exaggerate in characterising them as grievously injurious to my official position, and tending to the subversion of discipline in this establishment; and I have evidently no protection from a repetition of them, except through the intervention of a higher authority.

"Of these acts, those referred to under 1, 2, 3, formed the subject of a prolonged correspondence between the First Commissioner and myself; that under 4, I brought to the notice of Mr. Stansfeld, and the result was the abandonment of the proposal; that under 5 will, I venture to hope, be revoked by your authority. I refrain from commenting on these acts of the First Commissioner in reference to their seriously interfering with the execution of my peculiar and multifarious duties here.

"These include the labours of a Scientific Botanist, a Horticulturist, and the administration of Public Gardens, Museums, and Pleasure Grounds, frequented annually by upwards of 600,000 persons.

"Besides the living collections, I have the direction of the largest and by far the most frequented Herbarium (by botanists and amateurs) in existence, and a very extensive Library.

"I conduct, without a secretary, a responsible and onerous correspondence with Foreign and Colonial Gardens, as also with the Admiralty and Indian and Colonial Offices, on all subjects connected with Horticulture, Forestry, Botany, and the appointment of officers to duties in connection with these matters, and the introduction of useful plants everywhere.

"I have, further, the editorship or control of various botanical works now being published, by order of Government, at Kew; and I have to devote every moment that I can spare from my duties to maintaining, by researches and publications of my own, a position as a Scientific Botanist.

"Until the accession of Mr. Ayrton, I have been enabled to fulfil these duties with satisfaction to myself, having been treated with uniform confidence, consideration, and courtesy by my superiors. I was invariably consulted on all prospective changes affecting my own and my subordinates' positions and duties. On the revision of my estimates at the Board, before their transmission to the Treasury, I was referred to; and amongst my other current duties was the control of the construction and repairs of the hot-houses and heating apparatus throughout this establishment.

"Subsequently to Mr. Ayrton's accession, my position has been materially changed in all these respects. He had hardly entered on his duties when he hastily administered to me a wholly unmerited reprimand (the first I ever received), and his last act (known to me) has been to take from me the above-mentioned control, without pretext, warning, or subsequent intimation.

"I venture to hope that this may be restored to me, if the reasons I have adduced in the enclosed letter to the First Commissioner are satisfactory to you. To these I would add, that in all similar establishments with which I am acquainted, in England or abroad, the opinion of the cultivator is entitled to the first consideration in all matters relating to plant-houses and heating apparatus; that to trust him with the care and treatment of invaluable collections, and make him amenable to the opinions of another in respect of the apparatus he requires, is as obviously wrong in principle as to refuse a surgeon his choice of instruments and hospital appliances. Nor would it be candid in me to withhold from you my conviction, that I have by this arbitrary act of the First Commissioner been lowered in the eyes of those who know no more of the circumstances than that I am deposed from the full control of buildings and apparatus which I was entrusted to erect and have still to use.

"Let me assure you, Sir, that I am unconscious of any feelings of personal animosity against Mr. Ayrton.

"Having regard to the tenour of the sentiments he is reported to have expressed in public, on accepting office, in respect of professional duties such as mine, I felt it incumbent on me to be especially circumspect in my conduct and demeanour under his rule. And in evidence of this let me add, that when still smarting under his unprovoked reprimand, I, at his special request, devoted many nights to examining and reporting upon various books and pamphlets on the public parks of England, France, and America, for his guidance—a labour not very congenial and wholly beyond my province as Director of Kew, and which I further undertook in the hope that it might lead the First Commissioner to judge more generously of the acquirements and duties of some of the officers of the department he controls.

"I am, Sir,

"Your most obedient Servant,'

"JOS. D. HOOKER, *Director*

"To the Right Honourable

The First Lord of the Treasury"

To this letter Dr. Hooker was honoured by a reply from yourself, couched in kind and considerate terms. You had communicated with Mr. Ayrton, and had received his explanations, which you forwarded to the Director of Kew, "in the hope that they would convey to his mind the assurance that there has been no

* Dr. Hooker's letter containing these charges was never answered, or even acknowledged, by Mr. Ayrton.

intention on Mr. Ayrton's part to disregard his feelings or withhold the consideration due both to his person and his office."

Stress of public duty is quite sufficient to account for the fact of your overlooking the serious omissions and inaccuracies of the First Commissioner's "explanations." These, however, were immediately pointed out to you by Dr. Hooker. His object in addressing you was not simply to complain of personal discourtesy on the part of the First Commissioner, but of five official acts subversive of discipline in the Kew establishment, and fraught with mischief to the public service. Had these acts merely affected him personally, he would have been perfectly willing to accept the assurance of Mr. Ayrton's consideration, though he failed to discover any trace of it either in his explanations or in the treatment which official papers sent from Kew continued to receive from the office of Works. He regarded it, however, as his duty, as an officer in the public service, to the Government and the scientific public, to spare no effort to procure a reversion of the policy introduced into the management of each and all of the departments of Kew (the Gardens, Museum, and Herbarium) by the present First Commissioner.

The specific acts enumerated by Dr. Hooker in answer to the request of the First Commissioner are thus summarised in a letter to yourself:—

"1. A transaction with my subordinate of a nature so new to my long experience of official life, and so repugnant to my principles, that I refrain from characterising it.

"2. Removing the Curator from his duties under me, without any communication with me.

"3. Empowering the Curator to act independently of me in regard to the times he should consider himself under my orders, and instructing me to make my arrangements in deference to his, and in concert with him.

"4. Submitting to the Treasury plans and estimates for extensive alterations in the Museum at Kew, without even informing me of his intentions; which works would have most seriously embarrassed me, as Director of the Museums, and would have involved a large expenditure, for which I believe no estimate was submitted, and which would have been in every respect detrimental.

"5. Superseding me, without previous or subsequent communication, in duties for the execution of which I held the Board's authority, and which I am of opinion should unquestionably be performed by the Director, *i.e.*, the control of the heating apparatus of the hot-houses, &c."

In Mr. Ayrton's letter of "explanations," which you considered so satisfactory, the first three of these charges are skilfully ignored, and the other explanations contain statements which are demonstrably at variance with fact.

In the very considerate note above referred to, which was addressed by you from Balmoral to Dr. Hooker, you say: "There must be some mistake about Mr. Ayrton's failing to see you at Kew, as he assures me that he paid the visit there for the very purpose of personal and friendly communication."

We respectfully ask you to consider how this "purpose" was carried out. Dr. Hooker was at home when the First Commissioner paid this visit to Kew. He omitted to inquire for the Director at his house, or at the Gardens, or of his subordinate, to whom Mr. Ayrton's visit was really paid. He held a conversation with this subordinate seriously compromising the Director's position and authority, which conversation he subsequently desired should not be communicated to the Director. The result of this conversation, moreover, was a communication to the Treasury affecting Kew, which was also kept from the knowledge of the Director. You will learn from these facts what the First Commissioner understands by "personal and friendly communication."

From its effects upon himself, Dr. Hooker could infer how disturbing the continual intrusion of this subject upon your attention must be. He was anxious to reduce this disturbance to a minimum, and therefore ventured to suggest that he should be put in communication with one of your private secretaries, to whom he might explain his position. To this request you, in the kindest manner, assented, and placed Mr. West in communication with the Director of Kew.

Sorely against his inclination, but driven to it by the necessities of the case, Dr. Hooker, at an interview with Mr. West on the 30th of October, distinctly pointed out the grave errors and omissions contained in the "Explanations" given by the First Commissioner to the First Lord of the Treasury.

The end of the year approached without any answer being made to these communications and representations, and towards the close of December Dr. Hooker wrote again to Mr. West, who thereupon replied that a plan was under the consideration of the Government which would materially alter his position with reference to the First Commissioner of Works. He was subsequently informed semi-officially that the scheme was maturing, and the hope was expressed that he would take no step likely to embarrass the Government. This was far from his wish or intention. But after waiting till the 21st of February, the Director was semi-officially informed that the Government plan for his relief, and for the protection of Kew, had been abandoned.

In the hope of a satisfactory settlement, the matter was subsequently placed by you in the hands of the Marquis of Ripon, and on the 13th of March, 1872, before a Committee of the Cabinet, consisting of the Marquis, Lord Halifax, and Mr. Cardwell, Dr. Hooker, by the desire of the Committee, handed in a memorandum containing a statement of the points wherein his relations to the Government required definition and correction.

The upshot of these friendly efforts was this: On the 15th of April, 1872, Lord Ripon was asked to convey the following verbal message from yourself to Dr. Hooker, which, the noble Marquis added, was to be regarded by the Director of Kew as a final answer to his appeal: "Mr. Ayrton has been told that Dr. Hooker should in all respects be treated as the head of the local establishment at Kew; of course in subordination to the First Commissioner of Works."

At this time the controversy had, unhappily, reached a pitch far too serious to be stilled by such a message. In a letter to your private secretary, written immediately subsequent to the interview on the 30th of October, Dr. Hooker put his case thus: "I am at a loss what to say as to my future position under a Minister whom I accuse of evasion, misrepresentation, and misstatements in his communications to the First Minister of the Crown, whose conduct to myself I regard as ungracious and offensive, and whose acts I consider to be injurious to the public service, and tending to the subversion of discipline. Granting," he continues, "that the functions of a Director are restored to me, how am I to act when ordered to undertake works that involve wasteful expenditure, or are otherwise detrimental? I should be thankful for Mr. Gladstone's instructions on this head."

With great deference, we submit that the verbal intimation conveyed from you to Lord Ripon, and from Lord Ripon, through Mr. Helps, to Dr. Hooker, by no means met the issues here raised by the Director of Kew. He had suffered from the secret tampering of the First Commissioner with his subordinates; he had successfully resisted extravagant and foolish proposals made by the same Minister. His duties and responsibilities as regards the warming of the plant-houses had, to the imminent jeopardy of plants of the rarest value, been transferred, without notice or justification, to the Director of Works. Another class of duties had, in the same secret manner, been transferred to the Secretary of the Board of Works. Surely, Sir, your message through Lord Ripon, to all intents and purposes, empowered the First Commissioner to continue his course of studied indignity? Wrong upon wrong had been committed, which your answer left unredressed. No wonder that, notwithstanding his esteem and regard for you personally, and his respect for all authority rightly exercised, the Director of Kew should be driven to address to you, on the 22nd of April, a letter containing the following remonstrance:—

"The fact is, that the Directorship of Kew, which was formerly subordinated to the First Commissioner alone, has been by Mr. Ayrton officially subordinated to the Secretary of the Board and the Director of Works in London, and this surreptitiously, without fault found or notice of any kind given, the Director being left to discover his altered position as best he could: and the Director has further been subjected to a series of arbitrary and offensive measures on the First Commissioner's part, against which he could not defend himself. These measures being destructive of discipline, and injurious to this establishment, the Director felt it to be his duty to bring both their nature and consequences officially under your notice, and to seek from you that justice which (as he had been assured by the officers of the Treasury) could be obtained only through an official appeal to the Prime Minister.

"After eight months' interval, during which further arbitrary measures have been resorted to by the First Commissioner (and four of which were passed under the assurance that a measure for effectual relief was under consideration), the position of the

Director of Kew is not better, but worse than when it was first brought under your notice; for within that period his views with regard to the scientific and other appointments in the establishment have been absolutely set at naught.

"These circumstances are well known to the Director's subordinates. They know that he has been virtually deprived of authority and responsibility, and that his official appeals have been unanswered, and his complaints ignored. The basis of all order and discipline in the establishment is thus sapped, and the position of the Director rendered so anomalous, that his desire and determination to uphold the interests of Science at Kew, strengthened as they are by the moral and material support guaranteed to him, hardly suffice to render that position endurable.

"Your own practical wisdom will enable you to judge whether such a state of things is to be remedied by the curt and vague announcement (and such you must allow me to call it) which you have been good enough to make me through Lord Ripon.

"I have the honour to be, &c.

"(Signed) J. D. HOOKER"

Your verbal announcement through the Marquis of Ripon was subsequently defined by Mr. West as a private and friendly communication; and your secretary proposed that, as an official answer would be sent to Dr. Hooker's official application, the letter from which the foregoing extract is made should be considered as *non avenue*. Dr. Hooker, however, had shown his letter to friends whose counsel he had sought in this matter, and he therefore pleaded that you ought to see that which had been seen by others. With regard to the character of the verbal communication, Dr. Hooker had been given distinctly to understand that it was *official* and *final*. He, however, cheerfully accepted the assurance of your secretary, and awaited the official reply. It came, and we hereby respectfully submit it to your calm interpretation.

"Treasury Chambers, April 25, 1872

"SIR,—I am directed by the Lords Commissioners of Her Majesty's Treasury to acquaint you that their Lordships have been in communication with the First Commissioner of Works as to the matters contained in the letter which you have addressed to the First Lord of the Treasury.

"Their Lordships find that there is no difference of opinion upon the question of your position, which may be briefly defined as that of head of the local establishment at Kew, of course in subordination to the First Commissioner, and they anticipate no difficulty in the future regulation of the relations of that important establishment to the office of the Board of Works, in which the duties and powers of management are vested by statute.

"The present form of estimate for Kew Gardens laid by their Lordships before the House of Commons cannot now be altered, but it will be acted upon, and will in future be framed in accordance with this letter.

"I am, Sir,

"Your obedient Servant,

"(Signed) CHARLES W. STRONGE, *Principal Clerk*

"Director of Royal Botanic Gardens, Kew."

The concluding paragraph of this document, which is evidently the really important one, has been submitted to various persons accustomed to the language of official life, and we do not believe that a single one of them is sure of its meaning. Dr. Hooker, while willing to put the best construction upon it, thought it necessary to make a final inquiry, which was preceded by these remarks:

"I am most desirous of giving their Lordships no further trouble, and am, of course, prepared either cheerfully to submit to their decision, whenever it is clearly given, or to resign the office which I hold; but I am unable to find in your letter any judgment whatever upon the points contained in the accompanying Memorandum, which have all been submitted to the First Lord of the Treasury in my letters of August 19 and 31, or to the Committee of the Cabinet which I had the honour of attending on March 13 at Lord Ripon's residence.

"I trust that their Lordships will observe, that in seeking their decision on these several questions, I am raising no superfluous difficulties, but that it is impossible for me to understand my position until it receives their Lordships' authoritative definition in respect of the above matters.

"I am, Sir,

"Your obedient Servant,

"(Signed) JOS. D. HOOKER, *Director*

"Charles W. Stronge, Esq."

"MEMORANDUM

"1. Up to the date of the appointment of a Director of Works (under the Board of Works) in 1870, I was entrusted, by a special warrant of the Board, with the duty of preparing the estimates for the construction and repairs of the plant-houses, museums, and warming apparatus in this establishment. This warrant has been cancelled, without fault found, inquiry made, or intimation given, and the duty transferred to the Director of Works.

"Will you be good enough to inform me if it is their Lordships' decision that the powers conferred upon me by that warrant be restored to me?

"Previous to the accession of the present First Commissioner to office, I was consulted whenever changes were made in the estimates which it is my duty to submit to the Board, prior to their transmission to the Treasury.

"Am I to understand that hereafter the estimates will not be altered by the Board without giving me an opportunity of stating my views?

"3. I was entrusted with the custody and distribution to scientific bodies, &c. of the copies of the first volume of the 'Flora of Tropical Africa,' a work the publication of which I am officially instructed to superintend at Kew. On the publication of the second volume, the undistributed copies of the first were withdrawn, without inquiry, from my custody, and sent, together with those of the second volume, to the stationery office for sale.

"Would you be so good as to state whether I am in future to be entrusted with the custody and distribution of scientific works of which I (the unpaid editor) am entrusted with the publication by the Board?

"4. Previous to the accession of the present First Commissioner to office, I was consulted in all cases of prospective changes in the position and duties of my subordinates, and in all cases of proposed works that might affect my duties and responsibilities.

"I shall be glad to know whether I am in future to be consulted in regard to such matters.

"5. The Department of Works having been brought under the rules of the Civil Service Commissioners, all candidates for employment at Kew are liable to be chosen by open competition, except in cases where the qualifications required 'are wholly or in part professional, or not ordinarily to be acquired in the Civil Service,' as set forth in Clause VII. of the Commissioners' Rules. The present First Commissioner of Works refuses to allow me to take advantage of Clause VII. in cases both of purely botanical and horticultural appointments.

"Am I hereafter to be allowed to avail myself of this clause, when it is of importance to the public service that I should do so?

"6. The Director of Works having been given power to interfere in matters for which I am still in part responsible, I am anxious to know—

"Whether I am to consider myself subordinate to the Director of Works in such matters, and to submit to his control in respect of them. "JOS. D. HOOKER

"Kew, May 1, 1872"

To this letter no answer has been received.

It but rarely falls in either with our duties or our desires to meddle in public questions; and not until we found Dr. Hooker maimed as regards his scientific usefelness—not until we saw the noble establishment of which he has hitherto been the living head in peril of losing services which it would be absolutely impossible to replace; not, indeed, until we had observed a hesitation upon your part which we believe could only arise from lack of information—did the thought of interference in this controversy occur to us. Knowing how difficult it must be for one engrossed in the duties of your high position to learn the real merits of a conflict like that originated by the First Commissioner of Works, we venture to hope that you will not look with disfavour on an attempt to place a clear and succinct statement of the case before you.

That statement invites you respectfully to decide whether Kew Gardens are or are not to lose the supervision of a man of whose scientific labours any nation might be proud; in whom natural capacity for the post he occupies has been developed by a culture unexampled in variety and extent; a man honoured for his integrity, beloved for his courtesy and kindliness of heart; and who has spent in the public service not only a stainless but an illustrious life. The resignation of Dr. Hooker under the cir-

cumstances here set forth would, we declare, be a calamity to English science and a scandal to the English Government. With the power to avert this in your hands, we appeal to your justice to do so. The difficulty of removing the directorship of Kew from the Department of Works cannot surely be insuperable; or if it be, it must be possible to give such a position to the Director, and such definition to his duties, as shall in future shield him from the exercise of authority which has been so wantonly abused.

PROFESSOR AGASSIZ'S SOUTH AMERICAN EXPEDITION

I.

PROF. AGASSIZ'S Second Report to Prof. B. Peirce, Superintendent of the United States Coast Survey, dated U.S. steamer *Hassler*, Concepcion Bay, June 1, is given in the *New York Tribune* of June 26. The Report is of so great value and interest, that we reprint it entire :—

Since I sent my first report concerning erratics in the Southern Temperate Zone, I have been much engrossed with this subject, and have turned my attention chiefly that way, leaving to Pourtales the superintendence of the dredging, and to Steindachner and Blake the care of the zoological specimens.

On the eastern coast of Patagonia I had but little opportunity of adding to the information I had already obtained at Monte Video. It was not till we put into San Mathias Bay for some repairs that I could gather a few new facts. This bay is particularly interesting, because one can there compare the position of the tertiary beds in the cliffs bordering the Atlantic with that of similar beds in the cliffs along the northern shore of the bay. The southern exposure of the latter runs for nearly a hundred miles at about right angles with the sea coast. In both cases the outcrops of the beds are so nearly parallel with the surface of the sea, that whatever may have been their changes of level with reference to the ocean, they still retain the horizontal position in which they were deposited. It is of the utmost importance to remember this point when considering the distribution of the erratics over this part of the country with reference to the agency that may have transported them to their present resting-place. Among these tertiary deposits are well-marked banks of colossal oysters of considerable extent, one of which coincides with the level of low water, while another stands at least twenty-five feet higher. The difference of level between these two great beds of oysters is so considerable as to suggest a subsistence of the sea bottom during the deposition of the tertiary beds. Higher up there are outer layers full of smaller fossils—some about ten, others about twenty feet above the second oyster-bed. The oyster-beds are perfectly parallel with one another, and separated by thin layers of clay and sand. And so, also, are the upper tertiary beds containing the smaller fossils. Among these, one bank consists almost entirely of large numbers of a species of *Scutella* with a single perforation in the posterior interambulacral area. This bank is particularly well marked. A bank of hard sand higher up is also conspicuous, and so is another of hard clay standing about 100 feet above the sea-line.

As we shall see hereafter, and as Darwin has already stated, these tertiary beds extend all over eastern Patagonia, including the Straits of Magellan as far as Sandy Point. In consequence of disintegration the harder beds form as many retreating shelves, like stairs, upon the slope of the shore bank. Wherever surface denudation has taken place these shelves give rise to terraces, stretching horizontally at various heights all over the plains of Patagonia. The scenery at Cliff End reminded me somewhat of Gay Head and its tertiary formation, except that the upper part of the Cliff consisted chiefly of sandy clays, alternating with which are two distinct horizontal beds of considerable thickness, formed entirely of pebbles, rather small and uniform in size. These pebbles vary from the dimensions of a pea or a hazel nut to that of the fist, or more; but there are no boulders or large fragments of rock among them. It is noteworthy that, while these pebbles alternate in regular stratification with the sandy clays in the upper part of the cliff, they also occur upon the shelves below. In the latter case, however, they form only superficial deposits, and do not penetrate with the beds on which they rest into the interior of the strata. It has occurred to me that similar superficial accumulations of pebbles upon the shelves bordering the bed of the Santa Cruz River may have been mistaken by Darwin for indications of successive upheavals. It is certain that there are no beaches here, marking successive steps of the upheaval of the country. What Darwin has considered as evidence of a gradual rise of the shore are the denuded surfaces of the horizontal tertiary deposits which everywhere form parallel terraces. As for myself, I see here no evidence of upheaval except the level of the fossil beds of oysters and other fossils in the tertiary beds above the water, and the presence of fresh shells of living species upon and above the shore banks. These, however, only indicate that an upheaval has taken place since the deposition of the tertiaries, and while the shells now living already existed, without pointing to the rise by successive steps. Still less does it appear to me that the country has been submerged during the transposition of the erratics. Toward the west end of San Mathias Bay, at Port San Antonio, where extensive denudations have taken place in the very formations here described, these same pebbles occur again. But at Port San Antonio, instead of being well defined, continuous horizontal beds above the sea-level, they are shore pebbles, covering in a deep layer the whole extent of the beach, the inequality of which they follow. Their position here shows, beyond the possibility of doubt, that the whole set of beds above which they rest in regular stratification at Cliff End has been completely broken down and recently removed by the action of the sea, and the pebbles themselves thus brought to the sea level. Of course it follows that these pebbles have not been ground upon the modern beach, but upon an older foundation, corresponding at the time to the level at which the pebble beds now stand at Cliff End.

So far the facts. I am inclined to add, as an inference from subsequent observations made farther south, the relation of which to the facts above stated seem to me clear, that these pebbles have passed through the mill of a glacier's bottom before they were worked up by the floods into their present position in the beds of Cliff End and upon the beach of San Antonio; and I do not see why the floods which formed these denudations could not as well have been the result of the melting of ice at the close of the glacial period, as the result of a change of level between land and sea. As soon as geologists have learned to appreciate the extent to which our globe has been covered and fashioned by ice, they may be less inclined to advocate changes of level between land and sea, wherever they meet with the evidence of the action of the water, especially where no marine remains of any kind mark the presence of the sea. As I have already said, the small and remarkably uniform size of the pebbles in Port San Antonio is particularly noticeable, and also the fact that none but hard rocks, indeed, only the very hardest kind of rocks, are represented among them.

(To be continued.)

MEDICAL EDUCATION

A THOUGHTFUL address on "Medical Education in America," read by Dr. Bigelow to the Massachusetts Medical Society, has just been published in the form of a pamphlet. It discusses the important subject of the kind and degree of instruction in collateral sciences that should be given to the student of medicine during the short period of four years now at his disposal, and in the course of which he is supposed to have acquired the knowledge that will enable him to practise with advantage, or at least let us say with safety, to his patients, and with credit to himself. The question is of a very complex nature, and its difficulties can, perhaps, only be properly appreciated by those who have themselves been teachers, and who are not, therefore, likely to be led away by Utopian ideas of the amount of information that can be acquired by a man of ordinary abilities in this space of time even under favourable circumstances. It is very easy to say Educate to the highest point possible; let the student know something, at least, of Chemistry, of Botany, of Comparative Anatomy, of the origin, composition, and mode of manufacture of the drugs he uses; but the fact is overlooked that almost all he learns of these subjects is quickly cast aside when he begins to practise, because he finds that it is of no earthly use to him, and he regrets when too late the time he has spent in acquiring them, because it has led him to neglect the far more important matters of Pathological Anatomy, and the actual practice of Medicine and Surgery. "The Medical Student," Dr. Bigelow observes, "does not need to pick herbs from the field, or treat horses and dogs, or consider his parallelogram of forces before putting in a dislocated shoulder; but he does need to know how to recognise and exactly how to reduce a dislocated shoulder, how to recognise and treat human disease, and what are the medical properties of the drug which the farmer has grown, or the merchant imported for the apothecary. This is but a fair division of labour. He has enough to occupy him profitably and exclusively in his own immediate field of study, without wandering over the whole domain of knowledge—at least, at the mistaken behest of those who have a confused notion of a liberal education and large culture." "There is a fallacy in the idea of culture. Talent and power of application may, indeed, incidentally lead a man to eminence in several directions. But a cultivated, a literary, or even a scientific man is not necessarily the best physician." At the same time Dr. Bigelow concedes that there should be a certain latitude in the study of medical science on the ground that "no student or artisan is the worse for an outlook upon kindred arts and sciences which will help him to establish the true relations of his own, which will supply him with additional facilities and light for its pursuit, and with that training of his intellectual powers afforded by a systematic variation in their exercise." It must be remembered that all the sciences collateral to medicine have undergone extraordinary development during the past few years; and that to acquire a very moderate knowledge of chemistry, for example—such knowledge as would enable the student to analyse a single animal fluid, or even a fragment of a calculus—would be the undivided work of a year, and when accomplished he would scarcely be one step in advance of the man who had learnt a few rules of general application to the diagnosis of disease taught by an accomplished chemist.

Whilst agreeing with the general views expressed by Dr. Bigelow upon the education of the medical student as he now presents himself at the Hospital Schools at the age of eighteen or nineteen, it yet appears to us that the quality of the raw material, if we may call him so, might be immensely improved by the general adoption of a well-directed scheme of preliminary education. "One of the enormous follies of the enormously foolish education of England," said Sydney Smith, "is that all young men, dukes, fox-hunters, and merchants, are educated as if they were to keep a school or serve a curacy." Just so; and it is precisely in this respect that the education of the medical student of this country requires revision and improvement. The medical profession is not essentially a literary one. What is really required is a seeing eye and an understanding heart; the faculty of correct observation on the one hand, and on the other the ability to single out what is important amidst a multitude of unimportant particulars—in a word, judgment; and as this is capable of being immensely improved by exercise, it should surely be the point to which the education of the student should be directed. But, as a matter of fact, no line of education can be better adapted for the purpose in view than that of the medical student of the present day. From the beginning to the end it is or might be made a "questioning of nature." The grand defect of the system is that insufficient time is at the disposal of the student to master the details. He learns a little of many things; nothing well, unless it be his anatomy; but the advantage a knowledge of all would give him may be estimated in some remote degree by the value that teachers and students alike set upon this single acquisition. Seven years are not thought too long to make a master workman in any of the humblest trades; and yet the student is expected to acquire a fair knowledge of all the branches of a very wide, difficult, and profound intellectual pursuit in four short years, or if we read Dr. Bigelow aright, in three years in America. It is here we think, then, that some alteration is requisite. A boy who is going to enter the medical profession should be early set apart for that ministry. We are bold to say that a boy of fifteen knows or ought to know enough of Latin, Greek, and Arithmetic for any subsequent use he is likely to make of them. At this age he should be called upon to select what his future career shall be, and his education should be directed accordingly. From the inquiries of the Committee of Convocation of the University of London, *à propos* of the proposal for rendering the examination in Greek optional at Matriculation, it appears that there are several large schools of good repute in this country, as those of Cheltenham, Clifton, Haileybury, Marlborough, and Wellington, in which a "modern side" has been established, where attention is chiefly directed to the cultivation of mathematics and modern languages, Latin and Greek being considered as subsidiary branches of knowledge, or even completely omitted, as in the case of Greek at Cheltenham College.

We venture to suggest that in these, and, indeed, in every other large school in England, a third, or Natural Science department should be founded, in which Practical Chemistry, Field Botany, and Natural Philosophy, with the French and German languages, should form the subjects of study. We are confident that in the hands of competent teachers, a lad might obtain between the ages of fifteen and eighteen or nineteen, a very large amount of useful knowledge on these subjects, without any undue strain upon his intellectual powers; while we are convinced that such a scheme would prove successful in a pecuniary point of view; and that there would be ample funds, derived from the scholars in attendance, to pay the additional teachers that would be required. The instruction given need only be rudimentary; but it should be most precise and thoroughly acquired. Any chemist could select six elements, any botanist six natural orders, any zoologist six classes of animals, which, if thoroughly known, would constitute an invaluable training to the future physician. He would then enter the medical school with a well-cultivated mind accustomed to close observation, and prepared to profit to the utmost by the system of education now generally adopted.

ORNITHOLOGY OF NEW ZEALAND

Catalogue of the Birds of New Zealand, with Diagnosis of the Species. By Frederick Wollaston Hutton, F.G.S., Assistant Geologist. Published by Command. 8vo. (New Zealand, 1871.)

A History of the Birds of New Zealand. By Walter Lawry Buller, D.Sc., F.L.S., C.M.Z.S., &c. Part I. 8vo, coloured plates (London, 1872.)

BIRDS, as most people know, or ought to know, form the most important part of the vertebrate Fauna of New Zealand, and their importance is maintained not only when they are compared with their compatriots of other classes; but, when regarded in reference to members of their own class in the world at large, the birds of New Zealand offer so many singular forms that as a whole they deserve every consideration. Some of the most remarkable of these have already been mentioned by a distinguished writer in this periodical,* but perhaps hardly sufficient prominence was then given to the fact in the ornithology of New Zealand which seems of all others to demand attention; for, recent birds being divided into two great and trenchantly marked groups, of very unequal extent, the smaller of these groups (the *Ratitæ*) is found to contain six most natural sections, comprising, to take the most exaggerated estimate, less than two score of species, while the larger group (the *Carinatæ*), though perhaps not containing more natural sections, comprehends some ten thousand species. Now, two out of the six sections of this small group are absolutely restricted to New Zealand, and these two sections contain considerably more than half of the species known to belong to it. Thus, setting aside the Carinate birds of our distant dependency (and some of them are sufficiently wonderful), its recent Ratite forms—some twenty species, let us say—alone may be regarded as the proportional equivalent of one-tenth of the birds of the globe, or numerically, we may say, of an avifauna of about one thousand species.

* NATURE, June 23, 1870, and Jan. 5, 1871.

The birds of New Zealand, therefore, merit especial attention, and we are happy to say they receive it at the hands of the authors whose works are above cited. Taking the field in or about the year 1865, Mr. Buller, till then unknown to fame beyond the limits of his native colony, brought out an "Essay on the Ornithology of New Zealand," which at once attracted notice in this old world of ours. Some of his views were challenged by Dr. Finsch, then of Leyden, who had paid attention to this extraordinary avifauna, and a controversy ensued. This, to the credit of the controversialists, was carried on in a spirit very different from that in which many another war in natural-history circles has been waged, and the happy result is that on most points the combatants have arrived at the same conclusion, thereby giving assurance to the general public of its being the right one. The Essay we have mentioned may be regarded as the preliminary canter which a race-horse takes before he puts forth his full strength; and Mr. Buller's book, or that part of it which is as yet published, shows what he can do now that the colonial authorities have allowed him to come to England for the express purpose of completing his design.

Captain Hutton is known as an observer who, during several long voyages, had proved that some rational occupation could be found at sea even by a landsman; for, instead of devoting his energies to the ordinary time-killing amusements of shipboard, he watched the flight of the various oceanic birds which presented themselves, and speculated on the mode in which it was performed and the forces it brought into operation—to some purpose as the Duke of Argyll and Dr. Pettigrew have testified. The pamphlet whose title we give is in some respects a not less significant, if a less ambitious, work than Mr. Buller's; and though to the last must belong the crown of glory, we by no means wish to overlook the useful part which Captain Hutton's publication will play. If here we do not notice it further, it is because its value will be most appreciated in the colony itself, while Mr. Buller's beautiful book appeals to a larger public.

Of the baker's dozen of species included in this first part of the "History of the Birds of New Zealand," we propose to notice only those belonging to three genera, two of them quite peculiar to the country, while the third is, or was, found in the neighbouring islands of the same zoo-geographical province. The remaining eight species belong to types of far wider distribution; hawks, owls, and kingfishers present much the same features all the world over, and the New Zealand parrakeets do not much differ from their congeners which are found in other portions of the Australian region.

The Kakapo, or Owl-parrot (*Strigops habroptilus*), is without doubt one of the most remarkable of New Zealand birds. It has already been figured in these columns;* but perhaps a few more words about it may not come amiss. Its crepuscular habits seem to have kept it hidden from the earlier explorers, and it was not until 1845 that this singular form was made known to naturalists by the late Mr. Gray. Possessing ample wings, it disdains their use; and to such an extent has this desuetude reached that its osteology is thereby materially affected, and it stands alone among Carinate birds as having the keel of its breast-bone dwarfed into a mere ridge, such as is

* NATURE, Jan. 5, 1871.

familiar to the anatomist as the attachment of an ordinary muscle, instead of the highly developed crest common to every other known Parrot. Prof. Huxley has even suggested a doubt whether its sternum is ossified as in other *Carinatæ;* but this seems an excess of caution on his part, though we must admit that, until an investigator such as Mr. Parker has had the opportunity of examining an embryo, the question cannot be decided.

Of the Kakas (*Nestor*) Mr. Buller admits three species —*Nestor meridionalis*, *N. occidentalis*, and *N. notabilis*— the two first of which, we think, are barely separable. This very remarkable genus of Parrots includes some two or three other species, one of which, the *N. productus* of Phillip Island, is believed to have gone the way of so many animals that only inhabit small islands, and the same fate in all likelihood awaits its congeners. Most animals suffer from not being able to accommodate themselves to change of circumstances, but the very adaptability of the Mountain-Kaka, or Kea, will tend to its early destruction; for, though belonging to the groups of Parrots distinguished by their brush-like tongue, and deriving a considerable portion of their subsistence in a manner worthy of the Golden Age from the nectar of flowers, this wretched Kea (*N. notabilis*), since the introduction of sheep to New Zealand, has incurred the imputation of a fondness for mutton-cutlets *à l'Abyssinie**, and the charge, whether true or false, is likely to bring about its doom, since the shepherd is apt to practise what in good old times was called "border justice," and the species will probably suffer extinction before its guilt is fully proved or extenuating circumstances admitted. The Common Kaka (*N. meridionalis*), on the other hand, is ably defended by Mr. Buller as one of the most useful birds in the country; yet this also is rapidly diminishing. "In some districts," he says, "where in former years they were excessively abundant, their cry is now seldom or never heard," and though he adds that "in the wooded parts of the interior they are as plentiful as ever," it requires no prophetic eye to see that, with the extension of settlements, the Kaka must succumb.

The last bird we can especially mention is the Huia (*Heteralocha acutirostris*), known to our readers by a woodcut in these columns.† Mr. Buller, we must remark, has unhappily referred it to the Hoopoes (*Upupidæ*) with which, so far as we can see, it has nothing in common. Mr. Garrod has lately informed the Zoological Society that it belongs to the Starlings (*Sturnidæ*), and there can be little doubt that he is right in doing so; but it seems also to have some affinity to the Crows; and it is worthy of remark that one of its chief peculiarities, the diversity of the bill according to sex, is shared to some extent with an aberrant corvine form (*Nucifraga caryocatactes*). A distinguished zoologist has said that "such a divergence in the beak of the two sexes is very uncommon, and scarcely to be paralleled in the class of birds. It is difficult to guess at the reason of this, or to explain it on Darwinian or any other principles." Now, to us the difficulty does not seem greater than that presented by any other sexual characteristic, and on Darwinian principles the explanation is easy enough, if once the utility of the difference is established. This last is well shown by Mr. Buller's remarks on a pair of caged Huias which he kept for more than a year, and his account justifies the belief that had previously been entertained about them:—

"But what interested me most of all was the manner in which the birds assisted each other in their search for food, because it appeared to explain the use, in the economy of nature, of the differently formed bills in the two sexes. To divert the birds, I introduced a log of decayed wood infected with the huhu grub. They at once attacked it, carefully probing the softer parts with their bills, and then vigorously assailing them, scooping out the decayed wood till the larva or pupa was visible, when it was carefully drawn from its cell, treated in the way described above, and then swallowed. The very different development of the mandibles in the two sexes enabled them to perform separate offices. The male always attacked the more decayed portions of the wood, chiselling out his prey after the manner of some Woodpeckers, while the female probed with her long pliant bill the other cells, where the hardness of the surrounding parts resisted the chisel of her mate. Sometimes I observed the male remove the decayed portion without being able to reach the grub, when the female would at once come to his aid, and accomplish with her slender bill what he had failed to do. I noticed, however, that the female always appropriated to her own use the morsels thus obtained."

Here we must pause. Mr. Buller's book is in every way worthy of its subject, and we trust that we have shown that the subject is worthy of close attention—whether we regard the various forms of New Zealand birds from the point of view of their intrinsic interest, or from that of so many being now on the verge of extinction. It is easy to be wise after the event, and ornithologists at home do not in these days look back affectionately towards their predecessors who have let so many species pass away without tracing the process of extermination. We have above hinted at some of the causes of extinction which seem to be at work; and most of them, it is to be feared, are insuperable: but there is another, and possibly more powerful cause which is entirely under control. This is the silly mania for "acclimatisation" which has been so warmly fostered by many well-meaning though ill-advised persons, both at home and in the colonies, and nowhere more than in New Zealand. The English Acclimatisation Society fortunately came to an end, and before it had time to do any harm here; but its example has been mischievous in our dependencies. In a reckless way animals of extremely doubtful advantage have been transported to the antipodes, and there it seems impossible to deny that they will in a few years be found not only ousting the kinds which are less specialised, and therefore less able to meet them on an equal footing; but, unaccompanied by any of those checks which keep the whole of a natural fauna balanced, the importations will inevitably become the greatest of nuisances. The memory of the patriotic Scot who could not live without his thistles is not exactly blessed by Australians, and among the pilgrim fathers of New Zealand who will ultimately obtain an apotheosis, the members of their various acclimatisation societies will, we suspect, scarcely be reckoned.

OUR BOOK SHELF

The Messenger of Mathematics. New series. Edited by Messrs. Whitworth, Taylor, Lewis, Pendlebury, and Glaisher. Vol. i. (Macmillan and Co., London, 1872.)

THE twelfth monthly number of the new series of the "Messenger of Mathematics" has just been published. This offers a convenient epoch for estimating the aims and achievements of this new mathematical periodical.

The principal aim of the editors was stated in their introductory note to be the fostering of a continuous and ample supply of original investigations into the more and more specialised branches of mathematics. This originality was to be welcomed from whatever quarter it came—whether from mathematicians of established reputation or from junior students of the science; whether from the Universities of this country or from more distant centres.

The intentions of the editors have been fully realised by the publication of the twelve numbers now before us. The list of the contributors to these numbers contains nearly twice as many names as there are numbers of the magazine. And while in that list we find the names of some of the foremost mathematicians of the age, such as Messrs. Cayley, Routh, Stokes, and Townsend, we find also a considerably greater number of the names of junior students, some of whom have only recently graduated. The localities of the contributors are also as various as was intended, one of them, for example, writing from Queensland.

As regards the articles themselves, there are about four times as many on pure mathematics as there are on applied mathematics. Among the former we find, for example, such a simple matter as a very elegant proof, by Mr. Taylor, of Euclid, ii. 8, in which he makes a further step towards the elimination of the diagonals from the diagrams of the Second Book of Euclid. This construction is recommended to the attention of the Association for the Improvement of Geometrical Teaching. We find also such interesting contributions to the study of the higher geometry as Prof. Cayley's articles on the "Theory of Envelopes," and on "Penultimate Quartics;" Mr. Merrifield's article on "Families of Surfaces;" and Mr. Townsend's on "Confocal Quadrics." The articles on other branches of pure mathematics are as varied and as instructive as those on geometry. There is, for example, a spirited controversy between Prof. Cayley and Mr. Wilkinson, about the quantitative limitations which have, in more recent times, been imposed on the generality of Taylor's theorem. Prof. Cayley's plea for greater liberty of interpretation, and against confining our symbols in mathematics so exclusively to quantity, is especially effective and well-timed; for the more liberal our interpretations the vaster will be the domains we can overrun and occupy by means of our symbols, and the greater will be the tendency to that specialisation of efforts, or division of labour, which is so characteristic of modern mathematical research, and which the publication before us aims to combine by co-operation. Then there are "Exercises on the Integral Calculus," by Sir John Cockle, and papers on "Definite Integrals," by Glaisher; besides articles treating of many other subjects, too numerous to mention.

Among the articles on applied mathematics we find one by Prof. Stokes, on the "Compound Pendulum;" two by Mr. Routh, on the "Oscillations of a Heavy String," and an improved solution of a problem in the Astronomer Royal's "Undulatory Theory of Optics;" one by M. Leclert, on "Naval Geometry;" two by Mr. Hopkinson, on "Electricity;" and so on. There is also a most elegant model of mathematical style, especially suitable for intending competitors in mathematical examinations, namely, the solutions, by Prof. Cayley, of the whole of a Smith's Prize Paper, which are of the stiffest ever set.

With all its variety of contents, this magazine is still eminently readable, principally on account of an utter absence of that tendency to riot in new terminology, or scientific slang, which disfigures the pages of some modern mathematical writers. The typography is also very good.

We shall be well satisfied if vol. ii. maintains the high standard set by vol. i.; but we should be pleased to find in it a little larger proportion of articles on applied mathematics. There is much interest felt at present in such subjects as molecular mathematics; the theory of electricity and magnetism; the determination of the centres of gravity of ships; and such like problems in advanced theory or in complicated practice. We should be glad to see the miscellaneous portion of the magazine, containing notices and reports of the meetings of mathematical societies, reviews of books, &c., somewhat extended, even if the present very moderate charge of a shilling a number was somewhat exceeded in consequence. There has been, for example, no notice of the large and influential meeting held last January by the Association for the Improvement of Geometrical Teaching. Now, in that association the want of a monthly organ is much deplored. Why should not the "Messenger" fill that void? Perhaps, also, if the size of the "Messenger" were increased, space might be found for queries and notes from correspondents; and the name might be advantageously altered to "The Mathematical Magazine." But, in any case, every student who wishes to keep abreast of the current of contemporary mathematical thought should subscribe to this excellent little periodical.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Spectrum of Lightning

ON the 11th inst. there was a considerable thunderstorm in Patterdale, and I was again able to observe the lightning spectrum. Among other lines I saw one repeatedly near D_1 and about the centre of the bright yellow band between the two masses of atmospheric absorption lines in that neighbourhood. I also saw the line near *b*. Both correspond in position with principal air-lines.

But besides this line spectrum I repeatedly saw a continuous spectrum with bright bands, which might have been the low temperature nitrogen spectrum, though I feel no certainty that such was the case. There seems, however, no doubt that lightning gives two different spectra, one of bright lines, and the other continuous; unless indeed the latter be identical with the former, but with the lines much expanded. I do not think this is the case.

HENRY R. PROCTER

P.S.—Since writing the above there has been another thunderstorm, during which I more distinctly saw the band spectrum. I find that it is not the ordinary nitrogen band spectrum, but might be a very much expanded line spectrum. It is however difficult to understand the cause of so great a difference, for the line spectrum was very sharp and well defined. I thought I was able to recognise that the latter corresponded to the shorter and sharper peals of thunder. The spectrum showed no connection with the brilliancy of the flash. I recollect that in a brilliant thunderstorm which I lately witnessed at night in Syria, some flashes lighted up the dull foliage of the prickly pear to a vivid green; while others, showing the form of the landscape with nearly equal distinctness, left it almost colourless. I had then, unfortunately, no spectroscope.

Patterdale, Penrith, July 12

Aurora of July 7

THE very fine aurora of Sunday night, July 7, was well seen near Leenane, on Killary Harbour (lat. 53° 36′, long. 9° 45′, nearly), in the west of Ireland. Probably this is the most

westerly station in Europe from which the phenomenon has been observed with some approach to accuracy; and if the centre of the corona be, as it seems to be (*pace* some of your correspondents), an actual, substantive point, and not merely the effect of perspective, the following observations may help in determining its height above the earth. At 11.0 exactly, Greenwich time, the centre of the very well developed corona had an altitude of 68°, with an azimuth bearing of 21° E. of S., a little W. of magnetic S. (these measurements being taken as correctly as could be done with a good-sized compass furnished with a clinometer), and it was distant from α Lyræ (*Vega*) about 8° towards S.W.; this distance being afterwards diminished by the rotation of the earth. The aurora was observed independently by Messrs. Kinahan and Symes, of the Irish Geological Survey, in the same neighbourhood, and they also noted the proximity of the centre to the above-mentioned star. I do not trouble you with other details. M. H. CLOSE

Newtown Park, Black Rock, Dublin, July 13

I WITNESSED last night what must have been a somewhat brilliant display of aurora. From 10.45 P.M. to 11.0 P.M. slight breaks in the N.E. were brightly lit up with a rosy glare, and another break in the N. with the green rays. Coruscations of light flashed up from time to time, and were visible even through the clouds, which consisted of somewhat dense nimbus. The display in a clearer sky must have been decidedly fine.

Bridport, Dorset, July 8 J. EDMUND CLARKE

Registering Thermometer

MR. WHIPPLE and Mr. Bushell have shown great ingenuity in suggesting remedies for the copious condensation of moisture which takes place in the interior of the jackets of minimum thermometers on the grass.

Both their suggestions I have found fail to work a permanent cure; the chloride of calcium (only of use when the stopping is perfect) soon becomes super-saturated, and itself gives off moisture. The putty and sealing-wax hold good for about five or six months, and then the insidious moisture permeates again. Would it not be better to adopt my very simple plan of discarding the jacket altogether? It is absolutely useless, and no stopping is really effectual in resisting for long the daily extremes of heat and cold and damp and dryness these thermometers must undergo.

I have used a thermometer on the grass for the last three years entirely unmounted, and find its indications in no way effected by the loss of its outer coat.

CHARLES H. GRIFFITH

The Rectory, Stratfield Turgiss, Winchfield, Hants, July 5

Luminous Matter in the Atmosphere

I WAS much interested by M. Waldner's short article on "Luminous Matter in the Atmosphere" in the number of NATURE for Feb. 15, 1872. Being unable to see the particles described, I applied to him for further directions, and he was kind enough to inform me that they may be seen *à vision directe* with a telescope.

I have since found that many of the little bodies may be seen with the naked eye by shutting out the powerful direct and lateral rays. This may be done, *e.g.*, by partly closing the *jalousies* or outside shutters used here, and then looking for the particles at about the distance of quarter of a degree, or of the sun's radius from the border of his disc, when the sun is either just below the upper edge of the shutter, or immediately above the ledge of the house if it looks east and west. Shutters are not always necessary. I have just seen great numbers by standing on the border of the shadow thrown by the adjoining house. Even by holding my hat over my head I can perceive some of them. The chief object to be aimed at is to prevent the eyes from being dazzled by the direct rays of the sun. The same principle explains the reason why stars are sometimes seen during the day from the bottom of a well or through a telescope, and why the red protuberances of the sun become visible during an ordinary or artificial eclipse.

On the 9th and 10th current, and again this morning, there was a haziness round the sun, which gradually diminished as the angular distance from his disc increased, until the sky became beautifully blue at an angle of 25° or 30°. I found that the haziness was produced by the reflection of the sunbeams from innumerable little particles. Many of them were distinctly visible to the naked eye, but many more were seen with an opera-glass or telescope. They passed too rapidly to be counted, but fifty at least were in the field of my glass at one time. I am sure that this is no optical delusion, for several of my friends have seen them too.

What were these little particles? M. Waldner supposes them to be crystals of ice, and they certainly look like miniature snowstorms. Perhaps some of your readers may be able to decide whether the higher particles are composed of ice-like cirri, the loftiest of the clouds. But some of the corpuscles of the lower strata of the air are undoubtedly seeds, little organic substances, insects, &c. I have caught several feathery little seeds of this kind. They are almost imperceptible when seen against some white substance, and are so light that the slightest currents of air waft them to great distances.

Another instance of numberless little vegetable substances being blown here may be cited, namely, the pollen of the pine trees growing on the Landes. An unusually large quantity of this fell here on April 17, 18, 19, and 20, and may probably be traced to three extensive fires of pine woods sixty or eighty miles N.W. of Pau (April 14-16). The pollen was doubtless drawn upwards by a strong current of heated air, and then wafted to Pau by the wind, which blew in the right direction (April 17-19). The wind changed at Bordeaux on the 20th, and the pollen then fell (April 21-22) near Perigueux, nearly as far to the N.E. of the fires as Pau is to the S.E. A correspondent of the *Times* (April 30), mistaking the pollen for sulphur, announced that a shower of this substance had fallen here, and supposed that it was connected with the eruption of Vesuvius, which, however, did not begin until the 24th.

I would suggest that some record should be kept of the direction of the wind which these particles indicate in different strata of the atmosphere in fine weather. J. F. ANDERSON

Vibration of Glasses containing Effervescing Liquids

IT is known that a glass containing effervescing liquid will not give a clear note when struck, and that as the effervescence subsides the tone becomes more and more clear. When the liquid is perfectly tranquil the glass will ring as usual, but on re-exciting the effervescence the musical tone again disappears. Sir John Herschel (Encyc. Met., Art. "Sound"), who states that this experiment appears to have been originally made by Chladin, quotes it as an "example of the stifling and obstruction of the pulses propagated through a medium, from the effect of its non-homogeneity;" and, in explanation of the phenomena, he says:—"We must consider what passes in the communication of vibrations through the liquid from one side of the glass to the other. The glass and contained liquid, to give a musical tone, must vibrate regularly in unison as a system; and it is clear, that if any considerable part of a system be unsusceptible of regular vibration, the whole must be so."

The phenomenon, then, according to this explanation, is due to the fact that the liquid, during effervescence, becomes non-homogeneous, and thus obstructs the passage of the sonorous vibrations from one side of the glass to the other.

It is with much diffidence that I venture to express dissent from so eminent an authority as Herschel; but it does not appear to me that the above explanation is entirely satisfactory, for the following reasons:—

1. It seems probable that the sonorous vibrations pass *round* the glass rather than *across* it. For, if they pass across the glass, that will occur whether it contains water or air. Yet the musical tone of a glass containing air is not destroyed by suspending within it, so as not to touch it, a ball or cylinder of wool or cotton, although the sonorous vibrations certainly cannot pass freely through that substance.

2. If the non-homogeneity of the contained liquid be the cause why the sonorous vibrations will not pass, whence comes it that treacle, clear honey, &c., which are homogeneous fluids, destroy the musical ring of a glass fully filled with any of them?

The phenomenon presents itself to my mind as being due to a certain amount of vibration communicated to the glass by the agitation arising from the effervescence. This vibration—which can be easily heard by placing the ear close to the glass—interferes with that caused by striking the glass, and destroys more

or less the proper rhythmic movement necessary to the production of a musical note, according as the intensity of the agitation of effervescence is greater or less.

The dead sound of a cracked glass is probably owing to a similar cause. For in that case, as soon as the vibrations travelling round the glass arrive at the crack, the edges of which are wholly or partially in contact, they are transmitted from edge to edge, and as, owing to the friction of the edges one against the other, their vibrations do not synchronise, a reflex wave is impinged upon each, having a less velocity than the original wave. This reflex wave will correspond to the vibrations caused by effervescence. If the crack be cleanly cut out, so as to separate the edges by a well-defined interval, the glass will again emit a musical note. In the latter case, the sonorous vibrations, on arriving at the cut portion, return by the way they came, synchronising with those which they meet.

The dead sound of the glass, when filled with honey or treacle, is probably owing to the circumstance of these fluids being not sufficiently mobile to vibrate in unison with the glass; and thus they destroy its musical tone as effectually as if they generated an independent and non-synchronous vibration.

London, July 4 ALLEN BEAZELEY

The Names Cambrian and Silurian in Geology

WILL you allow me to express, as an humble worker among the rocks of North Wales, my sense of the high value of the contributions to your pages recently by Prof. Sterry Hunt on the "History of the names Cambrian and Silurian in Geology?" I have long felt—and have not hesitated to express my feeling—that a great wrong was done to Prof. Sedgwick when the North Wales groups of rocks from the Bala Beds to the Lingula Flags—the order of which he was the first to unravel in that difficult region—were unceremoniously engulphed in Siluria.

It has also appeared to me one of the greatest anomalies in English geological classification, that the magnificent and well-defined groups of North Wales should be typified by their attenuated and broken easterly outcrops in the Silurian district of South Shropshire. What Llandeilo section of Siluria is there that worthily represents the Arenig and lower Bala rocks immediately east or west of the Berwyn Mountains? What Caradoc section of Siluria is there at all worthy of the fine series of the Upper Bala rocks of Glyn Ceiriog? Of the unworthiness of the schists near the Stiper stones to represent the Lingula beds of North Wales, Prof. Hunt justly speaks in his papers.

I am glad that justice seems at last likely to be done to the veteran, Prof. Sedgwick, than whom a more philosophical geololist I am persuaded does not exist. Let but a sufficient number of scientific men resolve to use his older and truer, because more natural classification, and the justice will soon be complete.

D. C. DAVIES

ON THE VARIATION OF SPECIES AS RELATED TO THEIR GEOGRAPHICAL DISTRIBUTION, ILLUSTRATED BY THE ACHATINELLINÆ

IT has long been known that island species are usually different from, but allied to, those of the neighbouring continents. Darwin has also made us familiar with the fact that each of the Galapagos Islands has a fauna, and to some extent a flora, of its own. Other explorers have called attention to the somewhat limited distribution of species in the West Indies and on other islands. I have been informed by Mr. T. Bland, who has given special attention to the terrestrial molluscs of the West Indies, that if Cuba should be divided into two islands by the submerging of the central portion, about half of the species on either of these islands would be different from those on the other. Some of the most remarkable facts of this kind appear in the distribution of the Achatinellinæ on the Sandwich Islands. As they have never been fully recorded, I make the following brief statement of the leading facts, gathered from the results of personal exploration, and suggest a few inquiries.

Many types of the Sandwich Island Helicidæ have at different times been classed under the generic name of *Achatinella*. These widely differing forms have, in the structure of the shell, one point of correspondence that holds them together. The columella has a spiral twist which is more or less apparent in all. In most of the species this character is so strongly developed that the columella seems to be armed with a lamellated tooth revolving within the shell. This common characteristic, in connection with the fact that they are all confined within the limits of one small geographical area, affords sufficient reason for regarding even the most divergent of these types as belonging to one group. As the humming birds are peculiar to America, so the Achatinellinæ are peculiar to the Sandwich Islands.

Though the forms thus brought together evidently constitute a natural group, it has long been apparent that they should be classed under more than one generic name. Some of these genera are restricted to one or two islands.

Genera on Kauai

Several large turreted species of a peculiar type, found only on the island of Kauai, had been provided for at different times under the names of *Achatina*, *Achatinella*, and *Spiraxis*; but no resting-place was found for them till shelter was provided under the separate name of *Carelia*, given by H. and A. Adams. *Carelia turricula*, a species which is sometimes three inches in length and about an inch in diameter, may stand as the representative of this genus. Besides the six or eight species of *Carelia* which have been described, there are many other species of land shells peculiar to this island, the most northern and western of the group. Some of these are *Helices*; the others belong to *Amastra* (H. and A. Adams) and *Leptachatina* (Gould), two genera which are also represented on the other islands of the group. None of the species of this island present any of the brilliant colours that are so common in the shells of Oahu. The peculiar forms of some of the species, as of *Amastra Kauaiensis* and *Carelia cumingiana*, as well as the relations of these aberrant types to the types found on the other islands, render them objects of great interest.

Genera on Oahu

On the island of Oahu, which lies next to Kauai on the south-east, we find a remarkable development of the Helicidæ. The ground species belong to the two genera just mentioned, *Amastra* and *Leptachatina*. *A. ventulus* is an example of the former, and *L. vitrea* of the latter. Over twenty-five species of each have been found on this island. Two arboreal genera—the *Bulimella* (Pfeiffer) and *Helicterella* (Gulick)—are found only on this island. The ellipsoidal form, as in *B. rosea*, characterises the former; and the conical form, as in *H. apiculata*, the latter. Of *Bulimella* there are about thirty known species; of *Helicterella* thirty-five. The different species of *Bulimella* present a great variety of colours, ranging from bright green and rose, through yellow, brown, and ash, to simple black and white. The prevailing colours of the *Helicterella* are white, black, and brown, variously arranged in bands and stripes. The arboreal genus *Achatinella* (Swainson) may also be regarded as belonging especially to Oahu, as it is here represented by fifty-four species, and elsewhere by but three, which are found only on the island of Molokai, about fifteen miles to the east. *Achatinella producta*, about one inch in length, is one of the largest of the family. The *Auriculella* (Pfeiffer) is a genus of small arboreal species found on Oahu, and also on the islands to the east. Many of them are unnamed; but those on Oahu probably number more than ten. *Auriculella auricula* is given by Pfeiffer as the type. Two other arboreal genera — *Partulina* (Pfeiffer) and *Laminella* (Pfeiffer) — which find their chief development on the islands of Maui, Molokai, and Lanai, are represented on this island by three species each. The types, as given by Pfeiffer, are *Partulina virgulata*, found on Molokai, and *Laminella gravida*, on Oahu.

Number of Species and Varieties on Oahu, and the Regions they Inhabit

The number of species of Achatinellinæ on Oahu may be estimated at about 185, representing eight genera, but belonging chiefly to five. Besides these there are many small *Helices*, which would probably bring the whole number of the species of Helicidæ on Oahu up to about 200, the varieties numbering 800 or 900. None of these species—excepting, perhaps, one or two of the ground species, which are reported to have been found on the island of Maui—exist anywhere beyond the narrow circuit of this island, the extreme length of which is only 60 miles, with an average breadth of about 15 miles. Nor does any one species occupy a large proportion of even this area. Nearly all are confined to the forest regions skirting two ranges of mountains. The chief range, on the north-east side of the island, is about 40 miles in length. The forest region that covers it has an average breadth of five or six miles. The range on the opposite side of the island is about half as long, and has only about one-fourth as much forest land. The north-eastern side of the island, owing to its receiving the trade-winds when they first strike the island, enjoys a moister climate and possesses more luxuriant vegetation than the south-western side. We are therefore somewhat prepared to find that seven-eighths of the species, or about 175, are found in the former area, about 40 miles in length and five or six miles in width. Passing over innumerable minor variations, the varieties found in this area are no less than 700 or 800.

That so large a number of species and varieties of land molluscs should be found within so small an area is, I think, unparalleled in the records of conchology; but that this great number of forms should, with but two or three exceptions, be found nowhere beyond these narrow limits, not even on the other half of the same island, is still more astonishing. What shall we say when we discover that no one of these species is distributed over even half of this small mountain range; but that in most cases they are restricted to areas of from one to five miles in length? Have we found one of the "centres of creation"?

The principal facts in the geographical distribution of these forms are as follows:—

I.—*Facts relating to the Position and Natural Divisions of the Territory*

The Sandwich Islands are surrounded by a wider expanse of open ocean than any other islands of equal extent. The forms of Helicidæ on this group differ widely from those of other lands. Not only do we find distinct species and genera, but a separate group of genera.

The group of islands may be divided into four provinces, each of which has a separate set of species and possesses one genus or more that is peculiar to the province, besides other genera that are common to several provinces. (*a*) On Kauai alone is found the *Carelia*; (*b*) on Oahu, the *Bulimella* and *Helicterella*; (*c*) on Maui, Molokai and Lanai, the *Newcombia* (Pfeiffer); (*d*) on Hawaii, certain peculiar forms that have not yet been fully collected or classified. Kauai, which is separated from the other islands by the widest channel, has the forms that differ the most widely from those of the central part of the group.

Most of the species are confined to the forests of mountain regions; and where, as on Oahu and Maui, there are two regions of forest divided by several miles of grass country, the island is also divided into two sections, having but few, if any, species in common.

On the island of Oahu, the two sections which occupy separate mountain ranges are divided into many minor sections in the following manner. From each side of the main range project mountain ridges, which separate deep valleys a mile or two in width. Each of these valleys is a subordinate section, having its own varieties and in many instances its own species, which are found nowhere else.

II.—*Facts relating to the Variation and Affinity of Species*

Nearly all the species of one genus found on one mountain range are connected by varieties presenting very minute gradations of form and colour. Species of the same genus on different islands are not so completely connected by intermediate forms.

The degree of difference between several species of the same group is in proportion to their separation in space.

Nearly allied species, occupying neighbouring localities, pass into each other by all the intermediate gradations of form and colour, while those whose homes are separated by a distance of eight or ten miles, cannot be connected by minute gradations without bringing in some of the forms occupying the intermediate territory.

As the relations to each other of the valleys surrounding any mountain are determined by the shape of the mountain with its ridges, so are the relations of these species to each other, in the arrangement of their affinities and divergences, influenced by the same cause. As the geometrical relations to each other of valleys clustered around one central peak differ from those distributed on either side of a long range, so do the affinities and divergences (the structural relations to each other) of the species on one of the high solitary mountains of Maui differ from those on one of the mountain ranges of Oahu. On the eastern range of Oahu the species of *Achatinella* are distributed on both sides of the mountain in parallel lines, the extremes of divergence being in the forms at the ends of the range. But either on East Maui or West Maui, where the arrangement of the valleys is more concentric, the varieties of any one group of species converge so rapidly toward one central type, that it is difficult to distribute them into well-defined species.

III.—*Facts relating to the comparative Area occupied by Species of different Classes*

The average length of the area occupied by different species is perhaps five miles.

Field species have the widest range. Arboreal species have the narrowest range. Ground species found in forest regions have a medium range.

Many interesting questions are suggested by these facts. How can we account for the species being restricted in their distribution to such narrow limits? Why do not the species of North-eastern Oahu pass over their narrow bounds and become mingled throughout the whole extent of that short mountain range?

Questions Suggested

The minute gradations by which the species of each genus of the Achatinellinæ are connected with each other strongly favours the belief that many of them must have been derived the one from the other by successive variations. If created independently, why should there be such gradation? Why should the species of one group be so arranged that those intermediate in form are found in intermediate localities? It may be said that those of one group, which are gradated together by intermediate varieties, are not only from one stock, but are one species. If they are one species, how shall we account for the difference of size and form, the entire change of colour, and in many instances of habits, leading some of the so-called varieties to avoid plants that are chosen by other varieties living only a few miles distant, and to choose plants that are rejected by the others? Why should the *Achatinellæ* feed on Kukui trees (*Aleurites triloba*) in the eastern districts of the island, and in the north-western choose small shrubs, leaving the Kukui trees to the *Bulimellæ*? Whether we call the different forms species or varieties, the same questions are suggested, as to how they have arisen, and how they have been distributed in their several localities.

In attempting to answer these questions, we find it difficult to point to any of those active causes of accumulated variation, classed by Darwin as illustrations of

"Natural Selection." The conditions under which they live are so completely similar, that it does not appear what ground there can be for difference in the characters best fitting the possessors for survival in the different valleys in which they are found. The vegetation is much the same; the bird and insect enemies, so far as they have any, are the same. The north-east side of the mountain range is a little more rainy than the opposite side, but this does not account for the different forms found in the successive valleys on the same side of the range. In what respect can the conditions of survival to which *Achatinella Stewarti* is subjected in Manoa, differ from those under which *A. producta* lives in Makiki, only a mile distant, or from those in which *A. varia* is placed in Palolo, three miles away? There is no reason to doubt that some varieties less fitted to survive have disappeared; but it does not follow that the "Survival of the Fittest"—(those best fitted when compared with those dying prematurely, but equally fitted when compared with each other)—is the determining cause which has led to these three species being separated from each other in adjoining valleys. The "Survival of the Fittest" still leaves a problem concerning the distribution of those equally fitted. It cannot be shown that the "Survival of the Fittest" is at variance with the survival, under one set of external circumstances, of varieties differing more and more widely from each other in each successive generation. The case of the three species under consideration does not seem to be one in which difference of "Environment" has been the occasion of different forms preserved in the different localities. It is rather one in which varieties resulting from some other cause, though equally fitted to survive in each of the three localities, have been distributed according to their affinities in separate localities. There is no reason to think that *A. producta* is not as well fitted to live on the Kukui trees that abound in Manoa and Pololo, as on the same trees in Makiki. Again, is the "Survival of the Fittest" sufficient to explain their being kept within these extremely narrow limits since they were produced? One would at first suppose that, in the course of a few years, or in a few hundred years at the farthest, the three species would have been diffused throughout this area of only five or six square miles which is now divided between them.

We seek in vain for an explanation of these facts in the still further principle of variation, set forth by Herbert Spencer under the effects of change in use, and discussed by Prof. Cope under the names of "Acceleration and Retardation." This cause of accelerated variation has influence only where there is a difference in the "use, either compulsory or optional." If, on the one hand, the change is compulsory, it must be owing to a change in external circumstances. But in the case of these three species we are unable to find any difference in their circumstances requiring change. Their enemies are the same, the climate is the same, and they undoubtedly eat the same food, for the chief resort of all is the Kukui tree. If, on the other hand, the change in the use is optional, and without reference to change in circumstances, it belongs to the class of spontaneous variations, and does not explain why those of one type of variation (or of one kind of choice) should be brought together and limited to so small an area.

Relations of the Genera

The relations of the genera of Achatinellinæ involve problems of still greater interest, but more difficult to penetrate. The limits of this paper render it impossible to do more than to give some of the most striking facts, and indicate some of the questions that arise.

Through the varieties of *A. oviformis* and *B. Sowerbyana*, the genus *Achatinella* passes by minute gradations into *Bulimella*; but connections of this kind have not been noted between the other genera.

The family is divided into two natural groups of genera. The first group consists of seven genera: *Achatinella*, *Bulimella*, *Helicterella*, *Partulina*, *Newcombia*, *Laminella*, and *Auriculella*. These are all arboreal in their habits. In form they are either sinistral, or both dextral and sinistral. The second group consists of three genera: *Amastra*, *Leptachatina*, and *Carelia*. With but few exceptions, the species of *Amastra* and *Leptachatina* live on the ground and are of dextral form. I am not informed concerning the habits of *Carelia*, but the structure of the shell and its invariably dextral form show that it belongs to this group.

Of the second group, *Carelia* is found on Kauai, the most western of the Sandwich Islands. The two remaining genera are found on all the islands. The first, or arboreal group, is represented on all the islands except Kauai. The separate genera are more restricted in their distribution. Two are found only on Oahu, a third on Oahu and Molokai, a fourth on Molokai and Maui, and the remaining two on several islands.

The genus *Helix* is represented on all the islands. So far as I know, the species all live on the ground, and are all dextral in form. They are all small in size, with spire very much depressed, and have no trace of the peculiar twist in the columella which characterises the Achatinellinæ.

Why should nearly all the ground species be dextral, and many, if not a majority, of the arboreal species be sinistral? Does this fact point to one common origin for the arboreal genera, and a separate origin for the ground genera? Or are we to suppose that arboreal habits tend to produce sinistral forms? The few species of *Amastra* which are found on trees retain the dextral form that belongs to the allied species living on the ground.

Facilities needed for the Study of Variation of Species

I am fully persuaded that the study of allied forms in their geographical relations is one of the richest fields open to the naturalist. He may here reap a harvest of facts throwing light on many of the questions that are now occupying the special attention of the scientific world.

To afford suitable opportunity for such studies, it is necessary that certain sections of our museums should be devoted to the exhibition of objects in an arrangement more strictly geographical than anything that has yet been attempted. The leading feature in the arrangement adopted by Agassiz in the museum at Cambridge, Massachusetts, is the geographical grouping of objects; but for the fuller presentation of the curious facts of geographical distribution, it is further needed that in certain wisely chosen families the objects should be laid down in their actual geographical relations, as on a map. It is not necessary that the map on which they are arranged should be as mathematically correct as a nautical chart. It will be sufficient if cases are prepared, approximately representing the territory or territories chosen, with subdivisions representing the different localities in which the specimens have been found.

Collections for such a purpose should be made with scrupulous care. The locality of every object should be noted with great minuteness. In collecting shells at the Sandwich Islands, noting the name of the island is not sufficient, nor yet the name of the district. Each valley, with its area two or three miles in length, and but one or two miles in width, needs to be separately explored, and all the shells labelled with the name of the valley. To show the relations of the species to each other, as complete a series as possible should be obtained of the countless varieties.

For this kind of study the fauna of the Sandwich Islands is of peculiar interest, on account of the number of forms, and the variety of relations presented within a small compass.

JOHN T. GULICK

EVANS'S STONE IMPLEMENTS OF GREAT BRITAIN*

II.

ONE of the arguments usually relied upon in support of the belief in fluviatile, as opposed to diluvial, agency in the formation of the deposits in which the Stone Implements are found, is founded on the assumption that the constituents of these quaternary gravels are petrologically such, and only such, as belong to existing river basins; and this fact, Mr. Evans says, holds good in France and England, and cannot be too often reiterated. Without pausing to consider how far this argument might avail as against those who, like Dr. Buckland, believe in a simultaneous and universal cataclysm, it seems hardly applicable to the conditions under which the implement-bearing drifts are found; for if the term petrological is to be understood as meaning rocks found *in situ* in the river basins, and thus native to the soil, then it is not the fact that the constituents of the gravels in question belong to those basins; for we know that they are often largely made up—in one instance cited by Mr. Evans to the extent of 50 per cent.—of the quartzose stones known as Lickey pebbles, and rounded fragments of jasper, quartz, and other foreign rocks. Such rocks certainly do not belong petrologically, in the proper sense of that term, to the river basins in which they occur, but to strata of a far earlier date. As Dr. Buckland has shown, the quartzite pebbles are derived from the New Red sandstone beds in Warwickshire and Leicestershire, and were at some remote period forced over the escarpment of the Oolite into the south and east of England. Whether they were brought in before or after the present river valleys were formed is not very clear, nor perhaps very material. It is incontestable that they were transported from a great distance, and possibly by the same forces that brought the flint gravels; and it is equally certain, in several instances, that their transport cannot be attributed to rivers now in action, because those rivers flow, as at Brandon, towards the quarter from which the stones were brought.

Nor, if it were certain that the intrusion of these rocks dated back to the Glacial Epoch, as is usually supposed, or to some other very distant period, and had thus become denizens, if not natives of the soil, could the inference which is drawn from the absence of extraneous rocks be regarded as satisfactory.

The occurrence of alternate elevations and depressions of the land above or below the sea level, during the post-glacial times, has been suggested by several English writers; and if we suppose that a district comprising the south of England and the north of France, corresponding, or nearly so, with that in which no boulder clay is found, to be sufficiently depressed, and then invaded by a deluge, the argument drawn from petrological conditions will cease to apply; for no rocks are found in the drift gravels but such as belong to the supposed deluge basin. A deluge of short duration would not necessarily introduce any foreign rocks into the submerged area, but would sweep into hollows and valleys those that came in its way; and even should the submergence be of long continuance, as in some provinces of Holland, it would leave no more traces than those exhibited in our drift gravels. That such a partial deluge was both possible and probable is evident when it is considered that a depression of 600 ft. would perfectly well effect it; and as we have evidence that the land has risen in several places 30 ft. and more within the historical period, it is not difficult to believe that in the infinitely longer time that probably intervened after the Glacial Epoch the same process of elevation may have been going on for many ages.

* "The Ancient Stone Implements, Weapons, and Ornaments of Great Britain." By John Evans, F.R.S., F.S.A. (London: Longmans and Co., 1872.)

The absence of all traces of a marine fauna, and the occasional presence of land and freshwater shells in these beds, are circumstances on which much stress is laid by the author; but when fully considered they hardly seem to warrant the inferences drawn from them. A marine fauna requires a marine flora for its sustenance, and unless the submergence had been of long duration this could not have existed. We find extensive marine deposits of older date, in which no marine organisms are ever seen; and if marine fossils are wanting in drift beds, those of the land and freshwater are usually equally wanting. We have, probably, hundreds of square miles of quaternary gravels, in which not a single specimen has ever been discovered. In those instances, comparatively rare, in which they occur in the implement-bearing beds, they are usually lying above the gravel, and may thus be ascribed to a later date; or if of an earlier date in some instances, their occurrence would not of necessity exclude diluvial action, as regards the gravels.

There is one interesting topic connected with these drifts, which Mr. Evans has not dealt with at any length, as, indeed, it barely came within the design of his work; but he seems to share the general opinion that the men who made and used the drift implements were contemporary with the hippopotamus, elephant, rhinoceros, and other animals, with whose remains they are often found associated. At present this is but a possibility, and it is an assumption founded on the fact of the bones and implements being often found in close proximity, but if, as seems probable, the implements were formed from stones found in the gravels in which they now rest, it can hardly be doubted that the bones were already in that gravel, and may have lain there for centuries. From their shattered and way-worn condition, they have evidently been subjected to much rougher usage than that which some of the flint implements have met with. But however this may have been, there can be no doubt, as Sir Charles Lyell has observed in the "Antiquity of Man," that "the fabrication of the implements must have preceded the reiterated degradation which resulted in the formation of the overlying beds;" a process for which vast periods must be allowed, and one which must have involved important geological changes. Amongst others we have very strong reasons to believe was the severance of our island from the Continent, an event, indeed, which, however brought about, could hardly have been unattended with important changes in the contour of the adjacent districts, and the courses of their rivers. When we contemplate the vast changes, geological, palæontological, and geographical, which our race seems to have survived, we are surprised to learn how very old we are, or, as Mr. Evans has better expressed it, the mind is almost lost in amazement at the vista of antiquity thus displayed.

It would seem, as might be expected, that notwithstanding the cosmopolitan character of these objects—for, as Mr. Evans's researches have shown, they are found in one form or other in every country on the face of the globe—certain forms are pretty well confined to certain localities, as if each of the tribes or families who used them had its own manufacture. The half-polished and polished celts of Norfolk, Suffolk, and Cambridgeshire vastly outnumber those which have been observed in all other parts of England, from which it would seem that these counties were more populous, or the people more advanced in the arts, than in the rest of the island, or possibly they may have been the manufacturing district of the period. As regards, however, the distribution of the drift implements, a far more suggestive and important circumstance is to be noticed. As Mr. Evans has observed, the district farthest north of the Thames in the gravels of which flint implements are at the present time known to have been found, is the basin of the River Ouse and its tributaries. They have, in fact, been found at one time or other, in every English county lying to the south-east of a line drawn from

the Severn to the Great Ouse, corresponding thus far with the great escarpment of the oolite, but they have never been met beyond that line; and it is an interesting subject of speculation to what the dearth of these objects in the country lying to the north-west is to be attributed. If it was habitable and inhabited, it is difficult to imagine a reason for their absence, especially as in Yorkshire and Lincolnshire there is abundance of suitable chalk flint. This line of demarcation is not very much out of that which separates the boulder clay districts from those in which no boulder clay is met with. May it not have been the case, that when the implements were fashioned, Scotland and the north-western parts of England were still submerged beneath the glacial sea, and that on their emergence the south-east became in its turn depressed?

Notwithstanding all that has been written on the subject, there seems to be still much doubt as to the uses for

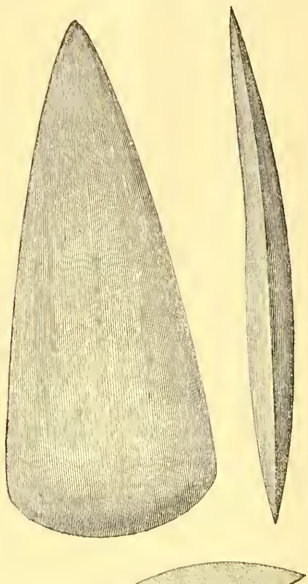

Fig. 1.—Polished Celt, Burwell Fen, Cambridgeshire

which some, and no inconsiderable number, of these objects were designed. For all useful purposes it would have sufficed that the cutting edge of a celt should alone be polished and ground; yet it is often, indeed usually, found that the entire surfaces of the faces and the sides exhibit a polish which could only have been obtained by long and apparently profitless labour. And not only so, but many of these are very fragile, being slightly made, and of delicate workmanship, and others are of such small dimensions, that, as M. Boucher de Perthes pointed out, they never could have been available for any kind of hard work. Many of these exhibit no signs whatever of fracture or even of scratching, either at the butt or the edge, indications which could not possibly have been wanting had they ever been used for weapons or tools. Besides which, while many of the districts in which they are found contain abundance of rocks suitable for all ordinary purposes, these implements are often made from Asiatic jade, jadeite, tremolite, serpentine, green porphyry, nephrite, and other stones of beautiful colours, and capable of taking a high polish, many of which must have been brought from great distances, and would have been very costly both to import and to work. The museums in Brittany, and particularly that at Vannes, are very rich in jadeite implements of this kind, but they are also found frequently both in England and Scotland. That of which a figure is here given (Fig. 1) was found in Burwell Fen, Cambridgeshire, and is described by Mr. Evans as being exquisitely polished, and a mottled pale green colour; the material is of a hard diorite, and as both faces are highly polished the labour bestowed on the manufacture must have been immense.

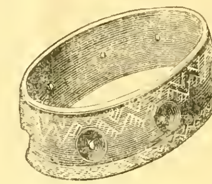

Fig. 2.—Jet Armlet, Guernsey

But if we conclude, as we must, with the author, that implements for which such beautiful and intractable materials were selected, could hardly have been in common use, we may indulge in some speculation as to what were the uses they were designed to serve, notwithstanding that, as Mr. Evans says, we have not sufficient ground for arriving at any trustworthy conclusion. M. Boucher de Perthes thought that they were deposited by the survivors in the graves of deceased friends, as useful to them on their resurrection, and he argued from this their belief in a future state. It seems, however, hardly probable that objects, many of which obviously could not be serviceable, should be placed in tombs under the belief that they would be so at some future date. In the absence of any more satisfactory explanation, it may be suggested that these things were intended by our remote

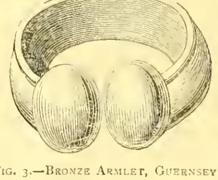

Fig. 3.—Bronze Armlet, Guernsey

predecessors to represent the deities whom they worshipped, and that by their varied sizes and shapes they indicated the ranks and orders of their idols. We may believe that men not having learned the art of representing the human or animal form, were obliged to content themselves with symbols of their divinities—it may be their Mars and Ceres—under the form of weapons of war, or instruments of agriculture. Nor is this so unlikely as it might otherwise appear, when we know that these celts are still objects of worship in India. Mr. Evans, quoting from the Proceedings of the Asiatic Society of Bengal, says that they are there venerated as sacred, and it is known that in a certain village in the Shewaroy hills some hundreds of polished celts, of varying sizes, resembling those found in England and Scotland, are preserved in a temple, arranged in rows. They are guarded with the utmost jealousy by the priests, each representing

some particular *swamy* or deity, and each receiving from time to time a dab of red or white paint, as a proof that the priest has performed before it the customary *poojah* or worship.

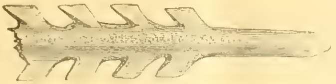

FIG. 4.—HARPOON HEAD, KENT'S CAVERN

This being so, the discovery of these implements in Europe may have some bearing upon an important ethnological question. We have good reason to believe that the dolmen-builders came, in the first instance, from India, for we find in Wilts and Berks, and elsewhere, exact counterparts of some megalithic structures, and those of a peculiar construction, which yet remain in the same Shewaroy district in which the celt worship is still practised. May we not then regard it as possible that the fabrication of polished implements, as well as the practice of dolmen building, originated in India, where they are still retained, and that these costly polished celts were brought hither by our Aryan ancestors, as the Israelites carried their Teraphim about with them, or as the Trojans, after the fall of their city, are represented in Virgil as carrying with them their household gods:—

"Ilium in Italiam portans, victosque penates;"

and that the worship was only abandoned here as men became enlightened, or were subjected to the dominion

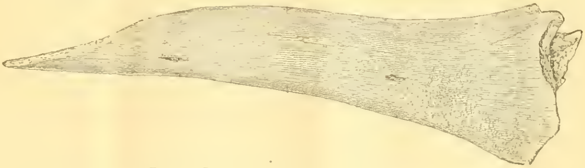

FIG. 5.—BONE AWL, KENT'S CAVERN. (1835.

of some race of a different theology? Since we find abundant traces of the Aryan language in our own, and of their sepulchral architecture in our dolmens, why should we not find in our fields and fens some of their idols? It is quite consistent with, and in a certain sense confirmatory of, such a belief, that in almost every country in which these things are found, they are regarded by the common people with superstitious reverence, as if the practice of adoration had in the lapse of ages merged in a vague and faint tradition of sanctity.

Nor is it any objection to this hypothesis, but the reverse, that these implements are usually found in and about dolmens, as at Tumiac and Mont St. Michel, where nearly seventy highly polished celts of imported materials—Asiatic jade and hard tremolite—were found ranged in regular order. It has been usual with almost all people, in all ages, that those things which they most esteemed in life should rest with them in their graves; and as we often find in our own country the priest's paten and chalice placed in his coffin, or the Anglo-Saxon's sword and shield laid beside him in the earth; so, possibly, these Prehistoric men may have wished that the stone idols which, when living, they adored—the Lares and Penates of their time—should be laid beside them in their tombs.

But in pursuing the train of thought suggested by our author, we had well-nigh forgotten his book, and we have only space to congratulate all those who are interested in these researches—and they are now many—on the ample and valuable additions which he has made to this new and most interesting chapter in the history of our race.

NOTES

THE following officers have been elected for the Brighton Meeting of the British Association:—President-elect—Dr. William B. Carpenter, F.R.S. Vice-Presidents-elect—The Earl of Chichester, the Duke of Norfolk, the Duke of Richmond, the Duke of Devonshire, F.R.S., Sir John Lubbock, Bart., M.P., F.R.S., Dr. Sharpey, Sec. R.S., Mr. Joseph Prestwich, F.R.S., Pres. G.S. Section A: Mathematical and Physical Science. President—Warren De La Rue, F.R.S. Vice-Presidents—J. Norman Lockyer, F.R.S.; Lord Rosse, F.R.S; Prof. H. J. Stephen Smith, F.R.S. Secretaries—Prof. W. K. Clifford, R. A. Proctor, A. C. Ranyard. Section B: Chemical Science. President—Dr. J. Hall Gladstone, F.R.S. Vice-Presidents—F. A. Abel, F.R.S.; Prof. Williamson, F.R.S. Secretaries—Dr. Mills; W. Chandler Roberts; Dr. W. J. Russell, F.R.S.; T. Wood. Section C: Geology. President—R. A. C. Godwin-Austen, F.R.S. Vice-Presidents—Thomas Davidson, F.R.S.; Prof. P. M. Duncan, F.R.S.; Rev. T. Wiltshire. Secretaries—Henry Woodward, Louis C. Miall, G. Scott, William Topley. Section D: Biology. President—Sir John Lubbock, Bart., M.P., F.R.S. Vice-Presidents—John Ball, F.R.S.; Dr. Beddoe; Prof. Flower, F.R.S.; Colonel A. Lane Fox; J. Gwyn Jeffreys, F.R.S.; Dr. Burdon Sanderson, F.R.S. Department of Zoology and Botany. Sir John Lubbock, Bart., M.P., will preside. Secretaries—Prof. Thiselton Dyer; H. T. Stainton, F.R.S. Department of Anatomy and Physiology. Dr. Burdon Sanderson, F.R.S., will preside. Secretaries—Dr. Gamgee, F.R.S.; E. Ray Lankester; Dr. Rutherford; Dr. Pye-Smith. Department of Anthropology. Colonel A. Lane Fox will preside. Secretaries—Dr. Charnock, F. W. Rudler, J. H. Lamprey. Section E: Geography. President—Francis Galton, F.R.S. Vice-Presidents—Clements R. Markham; Major-General Sir Henry Rawlinson, Bart., F.R.S., Pres. R.G.S.; Major-General Strachey, F.R.S. Secretaries—H. W. Bates, A. Keith Johnston, Rev. J. Newton, J. H. Thomas. Section F: Economic Science and Statistics. President—Prof. Henry Fawcett, M.P. Vice-Presidents—R. Dudley Baxter, William Newmarch, F.R.S. Secretaries—J. G. Fitch, Edmund Macrory, Barclay Phillips. Section G: Mechanical Science. President—Frederick J. Bramwell, C.E. Vice-Presidents—John Hawkshaw, F.R.S.; C. W. Merrifield, F.R.S.; Charles B. Vignoles, F.R.S. Secretaries—H. Bauerman, J. Gamble. The First General Meeting will be held on Wednesday, August 14, at 8 P.M. precisely, when Prof. Sir William Thomson, F.R.S., will resign the Chair, and Dr. W. B. Carpenter, F.R.S., will assume the Presidency, and deliver an Address. On Thursday Evening, August 15, at 8 P.M., a Soirée; on Friday Evening, August 16, at 8.30 P.M., a Discourse on In-

sect Metamorphosis, by Dr. P. M. Duncan, F.R.S; on Monday Evening, August 19, at 8.30 P.M., a Discourse by Prof. Clifford; on Tuesday Evening, August 20, at 8 P.M., a Soirée; on Wednesday, August 21, the Concluding General Meeting will be held at 2.30 P.M.

THE next meeting of the American Association for the Advancement of Science will not be held at San Francisco, as previously announced, but at Dubuque, commencing August 21.

THE following telegram respecting the Livingstone Search Expedition has been forwarded from the office of the Submarine Telegraph Companies in India:—"ADEN, July 11.—Stanley arrived, and leaves to-day by French steamer for Suez, with Livingstone's son. Has letters from Livingstone to the Government and friends. Found Livingstone unwell, but determined to go farther on, and not return before completing perfectly his work. Stanley's men return and accompany him."

IT is stated in *L'Institut* that the Académie des Sciences of Paris, at its last two sittings, has been again discussing in secret whether it will do itself the honour of admitting Mr. Darwin as a corresponding member in the section of Zoology.

THE chair of Natural History at Owens College has been divided. Prof. W. C. Williamson, F.R.S., retains the charge of Animal Physiology and Zoology and Botany; whilst Geology has been erected into an independent lectureship, and committed to Mr. W. Boyd-Dawkins, F.R.S., the curator of the Natural History Museum.

WE learn from *Les Mondes* that the French Budget Commission has opened provisionally to the Minister of Public Instruction a credit of 100,000 francs, to be appropriated to the collection of the special instruments necessary to the observation of the transit of Venus which takes place on December 8, 1874. The work of collection is being pursued with great activity at the Imperial Observatory, under the direction of M. Alphonse Martin.

THE Academy of Sciences in Bologna has announced that a prize of 1,200 *lire* (48*l.*), the "Aldini Prize," will be awarded to the author of the best scientific experimental essay on galvanism or dynamic electricity. Essays intended for the competition must be sent in between July 1, 1872, and June 30, 1874, and must be written in Italian, Latin, or French. They must be either written or printed; but, in the latter case, must not have been published previously to the two years above mentioned. Each essay is to bear a motto, and to be accompanied with an envelope stating the name of the author. They must be addressed to the Perpetual Secretary of the Academy of Sciences of the Bologna Institution.

THE *Melbourne Argus* states that valuable work is being performed with the great telescope at the Melbourne Observatory. At a recent meeting of the Royal Society, Mr. Ellery, the Government Astronomer, stated that some photographs of the moon had been obtained better than any he had any knowledge of. The picture of the moon taken in the telescope was about three inches in diameter, while the primary pictures of the photographs of the moon hitherto made public by Mr. De La Rue were only three-quarters or seven-eighths of an inch in diameter, though subsequently enlarged to something like two feet.

THE *Times of India* of June 21 prints at length the judgment of the Marine Court of Inquiry into the disasters attending the recent cyclone at Madras. The judgment contains the following chronicle of the weather changes during the three days preceding the cyclone:—On the afternoon of Monday, April 29, the wind shifted from the S.S.E. to the N.E., a bank of clouds forming to the S.E. The weather became gloomy, with lightning; the barometer falling slightly. On Tuesday morning the barometer had fallen, wind and sea had increased from the N. and E., with squalls, rain, and suspicious appearances generally, surf rising, and the current at the shipping changing to the S. During the night there were heavy squalls, with rain, thunder and lightning. It was blowing hard in gusts; sea increasing, and weather still getting worse. On Wednesday, May 1, the weather had a very wild appearance, a heavy squall with surf; wind about N.N.E. Very heavy squalls, with rain; fresh gale between the squalls. Towards afternoon it was blowing very hard; barometer falling. The barometric tide existed, but the mercury was lower in the tube, the current at the shipping setting stronger to the S. There appears to have been a break in the clouds to the N.E. in the evening, and the wind moderated, though still blowing hard, the barometer remaining depressed. Towards midnight on Wednesday the barometer commenced to fall rapidly, and the wind and sea increased to fury; several of the native vessels broke adrift, followed, after daylight, by the English vessels, to which this inquiry is directed. On consideration of the whole evidence, the court is "forced to a conclusion that during the day and night of Tuesday, April 30, the weather was such as should have induced any prudent man to take every precautionary measure for the safety of his ship; and that from Wednesday morning there should have been no reasonable doubt that the premonitory symptoms of a cyclone existed;" especially "at a season of the year when bad weather and cyclones are expected on this coast." Experience, the judgment declares, shows that the chances in favour of a vessel surviving a cyclone by putting to sea in time greatly preponderate. It will be seen from this that no blame whatever is attributed by the Court of Inquiry to Mr. Pogson.

THREE very remarkable paintings are now being exhibited at No. 7, Haymarket, called "Arctic Summer," "Crushed among the Icebergs," and "Arctic Wreckers." In the year 1869 the artist, Mr. Bradford, chartered the steamer *Panther*, of St. John's, Newfoundland, and, inviting Dr. Hayes, the well-known arctic explorer of America, to accompany him, sailed from the above port for the sole purpose of getting sketches of the hitherto unknown frozen north. Reaching the latitude of 76° N. in Melville Bay, he remained there until the middle of August, when the new ice began to form so fast that it was with great difficulty they could force their way through the pack. Two experienced photographers accompanied the expedition, and obtained most wonderful views of the arctic scenery. From the photographs, and his own sketches, Mr. Bradford has now produced these paintings, which must give a more perfect idea of the wonders of the arctic regions to those who have never visited them than any description could possibly do. It is difficult otherwise to realise the gigantic height of some of the ice-walls, the sea-fronts of the glaciers, from which the huge icebergs break off and drift southwards. Mr. Bradford will shortly publish a work, illustrated by over eighty of the finest photographs, showing the different phases of life in those regions—the great glaciers, fiords, mountains, Esquimaux life, icebergs, and the ice phenomena of Melville Bay; the edition will be limited to 250 copies.

THE first number is issued of a new monthly magazine, price 6*d.*, entitled *Grevillea*, a record of Cryptogamic Botany and its literature, edited by Mr. M. C. Cooke. It is intended as a medium of communication among cryptogamists, chronicling discoveries of new species, physiological observations, and other matters of interest, and will doubtless fill a useful place. In the present number, which is illustrated by a coloured plate, the fungologist, lichenologist, bryologist, algologist, and diatomologist will each find something to interest. If well supported by those interested in this branch of botany, it ought to become indispensable to all who wish to become *au courant* with the present position of cryptogamy.

PROFESSOR AGASSIZ'S SOUTH AMERICAN EXPEDITION*

II.

FOR reasons which I will explain presently, I would mention especially pebbles of a red porphyry, and others of a green compact epidote, as common in the Port San Antonio formation. The position of the Bay of San Mathias, its great length, and more particularly the depression or denudation at Port San Antonio, suggest the probability that the Rio Negro once poured its waters into this large gulf instead of opening directly into the ocean. I should add that while erratic pebbles occur in such abundance at San Mathias Bay, there are no hard rocks in place upon which the peculiar marks of glacial action could be perceived. Nor would these stratified banks of pebbles, even though unquestionably connected with the drift, afford in themselves any unmistakable evidence of glacial derivation.

As time and the circumstances of our vessel obliged me to renounce the hope I had cherished of seeing at least the mouth and the shore bluffs of the Rio Negro, Santa Cruz, and Gallagos Rivers, and also of visiting the Falklands, I could not connect my observations in San Mathias Bay with any other facts on the eastern coast of Patagonia or its outlying islands. But after rounding Cape Virgens we came into Possession Bay, where the geology along the shore was of a most interesting character. All along the northern shores of the Straits of Magellan the tertiary formation observed on the eastern shore of Patagonia is plainly distinguishable even from a distance by its horizontal beds, which are also visible upon the Fuegian coast. In Possession Bay we landed to examine more closely the character of the country, some of us with the intention of exploring more particularly the terraces above the shore bluffs; while others were bent upon a longer excursion to Mount Azmon and adjoining hills.

About a mile from the shore bluff I found, nearly 150 ft. above the sea level, a salt pool in which, to my great surprise, marine shells identical with those now living along the shore were abundant. They were in a perfect state of preservation, and many of them were alive; so that I gathered a number of specimens with the living animal, whi h I have preserved in alcohol. The most common were *Mytilus*, *Buccinum*, *Fissurella*, *Patella*, *Voluta*, &c., all found in apparently the same numerical relation as that in which they now exist in the sea below the cliff. The presence of this pool with its living inhabitants shows a very recent upheaval of the coast. The period at which it may have taken place it is hardly possible to determine without a more extensive survey. As the facts stand, it is a most valuable confirmation of Darwin's assertion of recent upheavals on this shore, published more than thirty years ago; though he attributes phenomena to this cause, and connects with it facts which had, in my opinion, a different origin and another significance. At the season of our visit to Possession Bay, in March, when autumn is approaching in this hemisphere, the pool was nearly dry, and the little water left in it was intensely saline. Dr. White has examined it chemically, and handed me the following report of his analysis:—"The specimen of water obtained from the pond at Possession Bay was found to contain magnesia, lime, sulphuric acid, chlorine, a small quantity of iron, and a trace of iodine. It was about $2\frac{1}{3}$ times as dense as ordinary sea water, as shown both by hydrometric observation and by the total amount of chlorine present; organic matter in excess." The shores of the pond showed plainly that in the rainy season it is three or four feet deep, when no doubt the water is more like sea water than at the time of our visit. From the innumerable tracks of guanacos, it must be the constant resort of these animals, and, indeed, during the day we saw many of them moving in that direction. A more palpable evidence of upheaval has not, as far as I know, been observed before. Dead marine shells scattered over dry land are not always conclusive evidence of the former presence of the ocean, for they may have been dropped by birds or other animals; but a salt pond more than 100 ft. above the sea level, with the same shells alive as those now found on the shore, could only be produced by an upheaval. The land beyond the first shore bluff is horizontal. It rises in regular terraces to about 400 ft. above the level of the sea. This is also the general level of the country, the surface of which is much ravined and furrowed. I counted eight such terraces above the beach. They all consist of tertiary deposits; but upon the beach itself three lower levels may be distinguished, their relative age being marked by the presence or absence of vegetation on the sand. Upon the third terrace, a little above and more inward than the salt pool, at the height of at least 150 ft. above the sea, I found a distinct moraine, in which the scratched pebbles were mingled with the simply rounded ones in as large a proportion as in any front moraine in actual contact with a glacier. This moraine was arched, with the convexity turned northward, and the abrupt slope southward, showing that the motive power which had brought and left it there must have moved from the south in a northerly direction. Higher up, to a level of about 400 ft. above tide water, there are also erratics scattered over the plain. At the level of 400 ft.—the highest to which I ascended—I saw a number of large, angular boulders.

Here are facts, then, of great significance in close proximity, namely, a pool containing marine shells alive, more than 100 ft. above the level of the sea, showing a very recent rise of the tract of land it occupied; and an accumulation of pebbles and boulders having all the characters of a glacial moraine, resting upon one of numerous terraces, which seem to mark successive upheavals of the country. That these retreating levels only simulate the successive steps of a gradual upheaval, and are in fact no evidence of such an occurrence, is proved by the geological constitution of the ground, which is entirely made up of regular tertiary beds, without a trace of shore pebbles. Darwin, who has also observed the phenomena of subsidence and upheaval characteristic of this region, was led to believe that the drift was scattered over Patagonia by icebergs while the country was submerged. The moraine upon one of these terraces mentioned above shows, however, that the upheaval must have taken place before the dispersion of the drift, and not after. I say nothing here of Pourtales's very interesting discovery of an extensive field of extinct volcanoes to the north of Possession Bay, of which Mount Azmon is the largest, since he has already sent you an official report on the subject. His observations are among the most valuable results of our geological work. The suggestion presents itself at once that the upheaval of the region may be connected with the former activity of those volcanoes. Throughout the eastern part of the Straits of Magellan the shores exhibited tertiary formations such as we had traced along the Atlantic coast of Patagonia and in San Matthias Bay. Of course in deposits of this kind we could not expect to find any trace of smooth polished rocks.

The last localities of recent geological age which we examined carefully were Elizabeth and Magellan Islands. The latter is almost entirely made up of glacial drift, among which there are a good many large and small boulders with very smooth surfaces and characteristic scratches, and some of them are of the same red porphyry and epidote mentioned before. At Sandy Point large accumulations of boulders are scattered over the whole country, and the streets of the settlement are paved with them. They are easily observed in their natural position on the banks of the river, and in the cuts of the railroad leading to the coal mines. Here the drift is auriferous. Señor Viel, governor of the colony, gave me very fine specimens of the gold collected in the immediate neighbourhood of the settlement. I was also much interested in the coal deposit. There are two considerable seams of coal, one 6 ft. 6 in. thick, and another, 80 ft. higher up, 3 ft. thick. The few species of fossils which I obtained there in great quantity left upon me the impression that the coal is not tertiary, but belongs to the cretaceous formation. The most characteristic of these fossils is an oyster, of the type of the *Ostrea deltoidea*, forming beds many feet in thickness.

After passing Sandy Point the country assumes a completely different aspect. The mountains rise to great heights on both sides of the channel, in consequence of which the region may be compared to the Alps, even though the loftiest peaks, such as Mount Sarmiento, Mount Darwin, Mount Buckland, Mount Barney, only measure from 6,000 ft. to 7,000 ft. But as their base is washed by the ocean, and their slope is very steep, they appear much higher than they really are.

The neighbourhood of Sandy Point will ever be especially interesting to Swiss geologists, from the fact that it recalls many familiar scenes. Pourtales and I greatly enjoyed the comparison with home scenery. In his work on the "Rocks of the Two Hemispheres," and in his "Kosmos," Humboldt repeatedly alludes to the striking similarity of the features exhibited by the inorganic world in regions very distant from each other, and I only follow in his footsteps if I say that Sandy Point and the tracks north of it recalled to me the Jura and the more level country at its foot, while the higher ranges to the south reminded me of the Alps. The comparison might be carried into detail without exaggeration. The first chain in sight from the channel,

* Reprinted from the *New York Tribune*.

in which the coal deposits are found, rises only to about 1,000 ft., and resembles the Neocomian hills skirting the western Jura; while the second chain, rising to about 2,500 ft., may be compared to Chaumont, or some other of the less elevated summits of the same range. Even the ravine leading to the coal mine brought back to me the gorges on Seyon, with its torrent; while the flats below stand in the same relation to the hills as the alluvial Pointe du Bied and the tertiary plain of Berex holds to the Jura. This resemblance is not simply superficial; it actually extends to the geological structure of the whole region. The higher mountains to the south, though recalling the Alps, should not be compared with the highest Swiss ranges, such as Mont Blanc, Mont Rosa, or the Bernese Oberland; they have more the character of the Osmonds. Mont Jura, for instance, when seen from the north, reminds one of the Niesen, or some of the conical heights rising above Meilleiries, such as the Cornette de Brise; when seen from the east it may be likened to the Untersberg, near Saltzburg. Mount Sarmiento, Mount Buckland, Mount Barney, and many others less known, have truly the character of the highest Alps. Mount Buckland resembles the Matterhorn very strikingly in form, except that its surface is entirely shrouded in ice.

It was not till we rounded Cape Froward that I felt confident that the range of hills immediately in sight along the channel we followed had assumed their present appearance in consequence of abrasion by ice. Now, however, that I have seen the whole length of the Straits of Magellan, have passed through Smyth's Channel, and visited Chiloe, I am prepared to maintain that the whole southern extremity of the American Continent has been uniformly moulded by a continuous sheet of ice. Everywhere we saw the rounded undulating forms so well known to the students of glacial phenomena as *roches moutonnées*, combined with the polished surfaces scored by grooves and furrows running in one and the same direction; while rocks of unequal hardness, dykes traversing other rocks, slates on edges, were all cut to one level. In short, all the surface features of the Straits of Magellan have much the same aspect as the glaciated surfaces of the Northern Hemisphere. Whenever the furrows and scratches were well preserved their trend was northern.

I have recorded carefully every locality having a special interest in reference to those facts. I will here only mention a few of the most characteristic ones. The first unquestionable *roches moutonnées* I saw were upon the nearest coast opposite Cape Froward—as the English maps have it—where the rocks are bent and twisted, as those of the Dent du Midi and the Dent de Morchi. Cape Frouart—for such is the French name given by Frezier to the southernmost promontory of the continent—is itself rounded and polished, most especially on its south-west exposure, with rugged crests as above the Grimsel in the Nägeli's Grath. All the hills between Snug Harbor and Wood Bay are equally rounded and polished to their very top. Even the wooded part of the slope shows the characteristic undulations of glaciated hill-sides. Many hills and mountains east and west of Cape Holland exhibited the same aspect. I was particularly struck with the appearance of a gentle slope between Cape Holland and Point Coventry, the surface of which exhibited some naked knolls distinctly glaciated, while the wooded part of the hill had the same form. All these mountains recall the Vor Alps, such as the Moleson, the Faulhorn, the Rhigi, and the Pilates, rather than the Alps themselves, even when entirely covered with *névé* or ice. These rounded knolls and glaciated surfaces penetrate frequently into the narrow coves which open into the main channel, in a north-south direction, at right angles with the Straits themselves—thus showing that the grinding agent must have moved from the south northward or from the north southward, and not from east to west or from west to east, as the Straits mainly trend. In Port Gallant, I saw large and small pebbles, and large boulders, many at least 6 ft. in diameter, and one measuring 12 ft. by 6 ft. and 5 ft., well rounded, and more or less polished, with rectilinear scratches in different directions all over their surface—in fact, such as are only found in genuine ground moraines.

The whole of Fortescue Bay, with the exception of a small land beach, on which we found a Fuegian camp, is covered with erratics. Even within high and low water mark many pebbles still show glacial scratches, though they are constantly tossed to and fro by the tides. Pourtales had the good fortune to be the first to see genuine glacier scratches, above Port Gallant, upon polished rocks in place. It was upon the surface of a quartz dyke traversing talcose slate. The trend of the scratches was west-north-west. There are *roches moutonnées* all the way from Fortescue Bay to Jerome Point, Cross Mountain included. Jerome Point itself is well polished, especially on the south side. York River Valley, which trends northward, is also well polished on both sides. Between the last two ranges of Jerome Point, westward, there is a cove trending northward, in which the *roches moutonnées* are as characteristic as upon the sides and face of the whole Point. The gorge opposite is equally *moutonnée* on both sides, showing that the denudation has not yet been the work of an agent moving east-west or west-east through the main channel. The two heads of the narrowest part of the straits (El Morion and Cape Gnod) are beautifully polished and rounded. The last range of Jerome Point seems to show that the abrading cause acted from S.S.W. to N.N.E. In Borgia Bay the ground is covered with large pebbles and boulders, some of the largest of which are rounded, polished, and scratched. Pourtales and Kennedy ascended the peak marked 1,923 upon the Admiralty map of Borgia Bay, and found *roches moutonnées* to the height of about 1,500 ft., while higher up the rocks were broken into rugged ridges. The whole scenery reminded me of the Abschwartz, above the glacier of the Aar. Some of the polished surfaces resembled, in the most surprising manner, places represented in my works upon the glaciers, and might have served as models for the illustrations I published of the glacial phenomena in Switzerland more than thirty years ago. No promontory in the whole extent of the straits, seen from either its eastern or its western side, shows as probable a strike-side of the polishing agent as the north and south exposures; leading to the presumption that the planing-machine has moved north and south, even though every surface seems almost equally well polished. Nothing indicates the fitful action of icebergs. Glacier Bay has also been for me a most fruitful field of study; but of this more in detail later. In the harbour of Sholl Bay there are several concentric moraines marked by boulders and kelp, which may have been deposited by the great glacier on the opposite side of the channel.

With all the evidences of glacier action constantly before our eyes, the journey from Cape Frouart to Cape Tamar was nevertheless tantalising to me, because it gave no opportunity for tracing the facts in unbroken continuity. The course of the Straits of Magellan bearing mainly in an east-westerly direction cuts everywhere at right angles, the effects produced by the southern ice-shoes upon the solid foundation of the whole track. Only after we had rounded Cape Tamar and passed Sholl Bay did we enter a channel bearing in the same direction with the glacial erosion, and thus affording an opportunity of following connectedly on the opposite sides of the whole channel, as far as the Gulf of Pennas, the traces left by glaciers upon the surface of the rocks. Here, as in reference to the Straits of Magellan, I shall describe only such localities as have a marked interest, reserving more details for another occasion. The facts spoke so plainly that even those not familiar with them were struck by their distinctness. Following the inside route through Smyth's Channel to the Gulf of Pennas, we were all the way within touching distance of the rocky walls of those narrow passages, so that nothing could escape us, and as the intricacy of the channels forebade travelling by night, we lost nothing in that way.

The Andes proper begin at Cape Providence, within the Straits of Magellan, but their alpine character is not strikingly developed south of Union Sound, even though at the bottom of Glacier Sound very high mountains with large glaciers may be seen. Mount Burney may be compared to Mount Sarmiento; still, throughout Smyth's Channel, until coming into Collingwood Strait, through Victory Pass, the scenery is very much like that of the Straits. In the southern parts of Smyth's Channel, I for the first time noticed an unmistakable difference between the southern and northern exposures of the nearer ranges trending N.S. Here it became every hour more plain that the strike-side of the glacial agency was upon the southern slope, and the lee side upon the northern. As soon as the Cordillera of Sarmiento opens into view the grandeur of the range is fully displayed. From the highest mountains glaciers depend to the sea level, which may be fairly compared to the most impressive glaciers of Switzerland. Throughout this region, as well as in other parts of the Straits, the nomenclature of the islands and mountains, as adopted upon the Admiralty chart, has a character very pleasing to a scientific man, and very creditable to those who have wished to connect the memory of their distinguished contemporaries and friends with their own investigations. Indeed, the names of all the prominent men of England, distinguished for their devotion

to science thirty-five or forty years ago, form now a part of the physical geography of these regions. With these are associated some foreign names which, however, are not always so happily applied, very eminent names being, in some instances, given to very insignificant localities. We had twice a beautiful view of Mount Burney; first coming up through Mayne Channel, where we had an opportunity of seeing the vast difference between its aspect when covered with snow to the very base, as represented by Dr. Cunningham, and as we saw it, with its upper part only shrouded in perpetual snow and ice. It will be long before the real level of perpetual snow is ascertained in these regions, as any boisterous day may change the appearance of a mountain range to an astonishing degree. The mountains to the north of Cape Providence, Mount Burney, the Cordillera of Sarmiento, and the mountain ranges east and north of Snowy Glacier, form part of one and the same chain, and are in reality the southern termination of the Andes. L. AGASSIZ

(To be continued.)

*ON THE SPECTRUM OF THE GREAT NEBULA IN ORION, AND ON THE MOTIONS OF SOME STARS TOWARDS OR FROM THE EARTH**

IN my early observations of the spectrum presented by the gaseous nebulæ, the spectroscope with which I determined the coincidence of two of the bright lines respectively with a line of nitrogen and a line of hydrogen, was of insufficient dispersive power to show whether the brightest nebular line was double, as is the case with the corresponding line of nitrogen.

Subsequently I took some pains to determine this important point by using a spectroscope of greater dispersive power. I found, however, that the light furnished by the telescope of eight inches aperture, to which the spectroscope was attached, was too feeble, even in the case of the brightest nebulæ, to give the line with sufficient distinctness when a narrow slit was used. The results of this later examination are given in a paper I had the honour of presenting to the Royal Society in 1868. I there say† :—

"I expected that I might discover a duplicity in the line in the nebula corresponding to the two component lines of the line of nitrogen, but I was not able, after long and careful scrutiny, to see the line double. The line in the nebula was narrower than the double line of nitrogen; this latter line may have appeared broader in consequence of irradiation, as it was much brighter than the line in the nebula." When the spark was placed before the object-glass of the telescope, the light was so much weakened that one line only was visible in the spectroscope. "This line was the one which agrees in position with the line in the nebula, so that under these circumstances the spectrum of nitrogen appeared precisely similar to the spectra of those nebulæ, of which the light is apparently monochromatic. This resemblance was made more complete by the faintness of the line; from which cause it appeared narrower, and the separate existence of its two components could no longer be detected. When the line was observed simultaneously with that in the nebula, it was found to appear but a very little broader than that line." I also remark :—"The double line in the nitrogen-spectrum does not consist of sharply defined lines, but each component is nebulous, and remains of a greater width than the image of the slit.‡ The breadth of these lines appears to be connected with the conditions of tension and temperature of the gas. Plücker states that when an induction-spark of great heating-power is employed, the lines expand so as to unite and form an undivided band. Even when the duplicity exists, the eye ceases to have the power to distinguish the component lines, if the intensity of the light be greatly diminished." I state further :—"I incline to the belief that it [the line in the nebula] is not double."

One of the first investigations which I proposed to myself when, by the kindness of the Royal Society, I had at my command a much more powerful telescope, was the determination of the true character of the bright line in the spectrum of the nebula, which is apparently coincident with that of nitrogen. From various circumstances, chiefly connected with the alterations and adjustments of new instruments, I was not able to accomplish this task satisfactorily until within the last few months.

Description of Apparatus

It seems to me desirable to give a description of the spectroscopic apparatus with which the observations in this paper were made. In the former paper, to which I have already referred, I gave some reasons* to show that the ordinary method of comparison, by reflecting light into the spectroscope by means of a small prism placed before one half of the slit, is not satisfactory for very delicate observations unless certain precautions are taken. I then describe an arrangement for this purpose, which, with one or two modifications, is adopted in the collimator constructed for use with the Royal Society's telescope. I give the description from that paper† :—

"The following arrangement for admitting the light from the spark appeared to me to be free from the objections which have been referred to, and to be in all respects adapted to meet the requirements of the case. In place of the small prism, two pieces of silvered glass were securely fixed before the slit at an angle of 45°. In a direction at right angles to that of the slit, an opening of about $\frac{1}{10}$ inch was left between the pieces of glass for the passage of the pencils from the object-glass. By means of this arrangement, the spectrum of a star is seen accompanied by two spectra of comparison, one appearing above, and the other below it. As the reflecting surfaces are about 0·5 inch from the slit, and the rays from the spark are divergent, the light reflected from the pieces of glass will have encroached upon the pencils from the object-glass by the time they reach the slit, and the upper and lower spectra of comparison will appear to overlap to a small extent the spectrum formed by the light from the object-glass. This condition of things is of great assistance to the eye in forming a judgment as to the absolute coincidence or otherwise of lines. For the purpose of avoiding some inconveniences which would arise from glass of the ordinary thickness, pieces of the thin glass used for the covers of microscopic objects were carefully selected, and these were silvered by floating them upon the surface of a silvering solution. In order to ensure that the induction-spark should always preserve the same position relatively to the mirror, a piece of sheet gutta-percha was fixed above the silvered glass; in the plate of gutta-percha, at the proper place, a small hole was made of about $\frac{1}{20}$ inch in diameter. The ebonite clamp containing the electrodes is so fixed as to permit the point of separation of these to be adjusted exactly over the small hole in the gutta-percha. The adjustment of the parts of the apparatus was made by closing the end of the adapting-tube, by which the apparatus is attached to the telescope, with a diaphragm with a small central hole, before which a spirit-lamp was placed. When the lines from the induction-spark, in the two spectra of comparison, were seen to overlap exactly for a short distance the lines of sodium from the light of the lamp, the adjustment was considered perfect. The accuracy of adjustment has been confirmed by the exact coincidence of the three lines of magnesium with the component lines of *b* in the spectrum of the moon."

The modifications of this plan consist in the substitution of a thin silver plate polished on both surfaces for the pieces of silvered glass. The opposite side of the silver plate to that from which the terrestrial light is reflected to the slit reflects the images formed by the object-glass to the side of the tube where a suitable eye-piece is fixed. This arrangement forms a very convenient finder, for it is easy to cause the image of the star to disappear in the hole in the silver plate. When this is the case the line of light formed by the star falls on the slit, and its spectrum is visible in the spectroscope. This collimator is so constructed that, by means of a coupling screw, any one of three spectroscopes can be conveniently attached to it.

This apparatus performs admirably; but it seemed to me desirable, for observations of great delicacy, to be able to dispense with reflection, and to place the source of the light for comparison directly before the slit. Formerly I accomplished this object by placing the spark or vacuum-tube before the object-glass of the telescope. The great length of the present telescope renders this method inconvenient; but a more important objection arises from the great diminution of the light when the spark is removed to a distance of 15ft. from the slit. I therefore resolved to place the spark, or vacuum-tube, within the telescope at a moderate distance from the slit. For this purpose holes were drilled in the tube opposite to each other, at a distance of 2ft. 6in.

* Phil. Trans. 1868, pp. 537, 538.
† Phil. Trans. 1868, p. 538.

within the principal focus. Before these holes short tubes were fixed with screws; in these tubes slide suitable holders for carrying electrodes or vacuum-tubes. The spark is thus brought at once nearly into the axis of the telescope. The final adjustment is made in the following manner:—A bright star is brought into the centre of the field of an ordinary eye-piece; the eye-piece is then pushed within the focus, when the wires or vacuum-tube can be seen across the circle of light formed by the star out of focus. The place of discharge between the electrodes or the middle of the capillary part of the vacuum-tube is then brought into the centre of the circle of light. The vacuum-tubes are covered with black paper, with the exception of a space about a ¼ inch long in the middle of the capillary part, through this small uncovered space alone can the light escape to reach the slit.

The accuracy of both methods of comparison, that by reflection and that by the spark within the tube, was tested by the comparison of the three bright lines of magnesium and the double line of sodium with the Fraunhofer lines *b* and D in the spectrum of the moon. I greatly prefer the latter method, because it is free from several delicate adjustments which are necessary when the light is reflected, and which are liable to be accidentally displaced.

Spectroscope A is furnished with a single prism of dense glass with a refracting angle 59° 42′, giving 5° 6′ from A to H.

Spectroscope B has two compound prisms of Mr. Grubb's construction, which move automatically to positions of minimum deviation for the different parts of the spectrum. Each prism gives about 9° 6′ for minimum deviation from A to H.

Spectroscope C is furnished with four similar prisms.

The small telescopes of the three spectroscopes are of the same size. Diameter of object-glass 1¼ inch; each is furnished with three eye-pieces magnifying 5·5, 9·2, and 16·0 diameters.

Spectrum of the Nebula of Orion

With spectroscopes A and B four* lines are seen.

First line.—With spectroscope B and eye-piece 1 and 2, the slit being made very narrow, this line was seen to be very narrow, of a width corresponding to the slit, and defined at both edges, and undoubtedly not durable. The line of nitrogen when compared with it appeared double, and each component nebulous and broader than the line of the nebula. This latter line was seen on several nights to be apparently coincident with the middle of the less refrangible line of the double line of nitrogen. This observation was on one night confirmed by observation with the more powerful spectroscope C.

The question suggests itself whether, under any conditions of pressure and temperature, the double line of the nitrogen-spectrum becomes single; and further, if this should be found to be the case, whether the line becomes single by the fading out of its more refrangible component, or in what other way the single line comes to occupy the position in the spectrum, not of the middle of the double line, but that of the less refrangible of the lines.

I stated in my former paper that when for any reason the light from the luminous nitrogen is greatly reduced in intensity, the double line under consideration is the last to disappear, and consequently a state of things may be found in which the light of nitrogen is sensibly monochromatic when examined with a narrow slit.† Under these circumstances the line of nitrogen appears narrower, and the separate components can be detected with difficulty, if at all.

I stated also that the breadth of the component lines appears to be connected with the conditions of density and temperature of the gas. As was to be expected from theoretical considerations, the lines become narrower and less nebulous as the pressure is diminished. My observations of this change seemed to show that the diminution of the breadth of the lines takes place chiefly at the outer sides of the lines, so that in the light from very rarefied gas the double line is narrower, but the space of separation between the components is not as much wider as would be the case if the lines had equally decreased in width on the sides towards each other.

When the pressure of the gas is reduced to about 15 inches of mercury, the line spectrum fades out to give place to Plücker's spectrum of the first order. During this process a state of things occurs when, for reasons already stated, the spectrum becomes *sensibly* monochromatic when viewed with a narrow slit and a spectroscope of several prisms. The line is narrower, and remains double, and has the characters described in the preceding paragraph.

As the pressure is diminished, the double line fades out entirely, and the spectrum of the second order gives place to the spectrum of the first order. When, however, the pressure becomes exceedingly small, from 0·1 inch to 0·05 inch, or less, of mercury, there is a condition of the discharge in which the line again appears, while the other lines remain very faint. Under these conditions I have always been able, though with some difficulty on account of the faint light when the necessary dispersive power (spectroscope B with second or third eye-piece) and a narrow slit are used, to see the line to be double, but it is narrower than when the gas is more dense, and may be easily mistaken for a single line. I have not yet been able to find a condition of luminous nitrogen in which the line has the same characters as those presented by the line in the nebula, where it is single and of the width of the slit.

Upon the whole I am still inclined to regard the line in the nebula as probably due to nitrogen.

If this should be found to be the case, and that the nebular line has originally the refrangibility of the middle of the double line of nitrogen, then we should have evidence that the nebula is moving from the earth. The amount of displacement of the nebular line from the middle of the nitrogen double line corresponds to a velocity of 55 miles per second from the earth. At the time of observation the part of the earth's orbital motion, which was from the nebula, was 14·9 miles per second. From the remaining 40 miles per second would have to be deducted the probable motion from the nebula due to the motion of the solar system in space. This estimation of the possible motion of the nebula can be regarded as only approximate.

If the want of accordance of the line in the nebula with the middle of the double line of nitrogen be due to a recession of the nebula in the line of sight, there should be a corresponding displacement of the third line as compared with that of hydrogen. For reasons which will be found in a subsequent paragraph, I have not been able to make this comparison with the necessary accuracy.

In my former paper* I gave reasons against supposing so large a motion in the nebula; these were based on the circumstance that the nebular line falls upon the double nitrogen line, which the present observations confirm. I was not then able to use a slit sufficiently narrow to show that the nebular line is single and not coincident with the middle of the double line of nitrogen.

I am still pursuing the investigation of the parts of this inquiry which remain unsettled.

Second line.—This line was found by my former comparison to be a little less refrangible than a strong line in the spectrum of barium. Three sets of measures give for this line a wave-length of 4,957 on Angström's scale; this would show that the line agrees nearly in position with a strong line of iron. At present I am not able to suggest to what substance this line belongs.

This line is also narrow and defined. I suspect that the brightness of this line relatively to the first line varies in different nebulæ.

Third and fourth line.—My former observations show that these lines agree in position with two lines of the spectrum of hydrogen, that at F and the line near G.

These lines are very narrow, and are defined; the hydrogen, therefore, must be at a low tension.

The brightness of these lines relatively to the first and second lines varies considerably in different nebulæ; and I suspect they may also vary in the same nebulæ at different times, and even in different parts of the same nebula, but at present I have not sufficient evidence on these points.† I regret that, in consequence of a continuance of bad weather, I have not yet been able to obtain decisive observations as to the possible motion of the nebula in the line of sight. With spectroscope B and eye-

* The fourth line was first seen in nebula 18 H. IV. (Phil. Trans. 1864, p. 441).

† Phil. Trans. 1868, pp. 540-546. Observations on this point were subsequently made by Frankland and Lockyer (Proc. Roy. Soc. vol. xvii. p. 453). It should be stated that they make no reference to my observations, though they refer to a purely hypothetical suggestion contained in the same paper.

* Phil. Trans. 1868, pp. 542, 543.

† Since writing this sentence I have seen a note by Prof. D'Arrest in the "Astronomische Nachrichten," No. 1,885. Speaking of the nebula H. IV. 37. he says:—"Sein Spectrum ist ausser von Huggins bisher nur noch von Dr. H Vogel untersucht worden. In No. 1,864, Ast. Nachr. theilt Letzterer mit, trotz er im Jahre 1871, im Widerspruch mit Huggins' Angabe, die Linie Neb. (3) = (2), bisweilen sogar (2) < (3) gefunden haben. Auch Huggins war dagegen im Jahre 1864 positiv (2) > (3). Ist Vögel's Beobachtung, wie ich nicht bezweifle, zuverlässig, so wird seine Vermuthung einer Veränderung hier in der That begründet sein, denn diesen Winter, namentlich im

piece 2, the lines appear to be coincident with those of hydrogen. In consequence of the uncertainty of the character of the first line, which is single, while that of nitrogen is double, this determination can now only be made by means of the comparison of the third line with that of hydrogen. This third line becomes very faint from the great loss of light unavoidable in a spectroscope that gives a sufficient dispersive power, and the comparison can only be attempted when the sky is very clear and the nebula near the meridian.

2. *On the Motions of some Stars towards or from the Earth*

In the early part of 1868 I had the honour of presenting to the Royal Society some observations on a small change of refrangibility which I had observed in a line in the spectrum of Sirius as compared with a line of hydrogen, from which it appeared that the star was moving from the earth with a velocity of about twenty-five miles per second, if the probable advance of the sun in space be taken into account.*

It is only within the last few months that I have found myself in possession of the necessary instrumental means to resume this inquiry, and since this time the prevalence of bad weather has left but few nights sufficiently fine for these delicate observations.

Some time was occupied in obtaining a perfectly trustworthy method of comparison of the spectra of stars with those of terrestrial substances, and it was not until I had arranged the spark within the tube, as described at the beginning of this note, that I felt confidence in the results of my observations.

It may be well to state some circumstances connected with these comparisons which necessarily make the numerical estimations given further on less accurate than I could wish. Even when spectroscope C, containing four compound prisms, and a magnifying power of 16 diameters are used, the amount of the change of refrangibility to be observed appears very small. The probable error of these estimations is therefore large, as a shift corresponding to five miles per second (about $\frac{1}{40}$ of the distance of D^1 to D^2), or even a somewhat greater velocity, could not be certainly observed. The difficulty arising from the apparent smallness of the change of refrangibility is greatly increased by some other circumstances. The star's light is faint when a narrow slit is used, and the lines, except on very fine nights, cannot be steadily seen, in consequence of the movements in our atmosphere. Further, when the slit is narrow, the clock's motion is not uniform enough to keep the spectrum steadily in view; for these reasons I found it necessary to adopt the method of estimation by comparing the shift with a wire of known thickness, or with the interval between a pair of close lines. I found that, under the circumstances, the use of a micrometer would have given the appearance only of greater accuracy. I wish it therefore to be understood that I regard the following estimations as provisional, as I hope, by means of apparatus now being constructed, to be able to get more accurate determinations of the velocity of rhe motions.

Sirius.—The comparison of the line at F with the corresponding line of hydrogen was made on several nights from January 18 to March 5. Spectroscope C and eye-pieces 2 and 3 were used. These observations confirm the conclusion arrived at in my former paper, that the star is moving from the earth; but they ascribe to the star a velocity smaller than that which I then obtained.

These observations on different days show a change of refrangibility corresponding to a velocity of from twenty-six miles to thirty-six miles per second. She part of the earth's orbital motion from the star varied on these days from ten miles to fourteen miles per second. We may take, therefore, eighteen to twenty-two miles per second as due to the star.

The difference of this estimate, which is probably below rather than in excess of the true current from that which I formerly made, may be due in part or entirely to the less perfect instruments then at my command. At the same time, if Sirius be moving in an elliptic orbit, as suggested by Dr. Peters, that part of the star's proper motion, which is then in the direction of the vesical ray, would constantly vary.*

Betelgeux (α *Orionis*).—In the early observations of Dr. Miller and myself on this star, we found that there are no strorg lines coincident with the hydrogen lines at C and F. The line H α falls on the less refrangible side of a group of strong lines, and H β occurs in the space between two groups of strong lines, where the lines are faint. On one night of unusual steadiness in the air, when the finer lines in the star's spectrum were seen with more than ordinary distinctness, I was able with the more powerful instruments now at my command to see a narrow defined line in the red apparently coincident with H α, and a similar line at the position of H β. These lines are much less intense than the lines C and F in the solar spectrum; there are certainly no bright lines in the star's spectrum at these places.

The most suitable lines in this star for comparison with terrestrial substances for ascertaining the star's motion are the lines of sodium and of magnesium. The double character of the one line agreeing exactly with that of sodium, and the further circumstance that the more refrangible of the lines is the stronger one, as is the case in spectrum of sodium and in the solar spectrum, and the relative distances from each other and comparative brightness of the three lines, which correspond precisely to the triple group of magnesium, can allow of doubt that these lines in the star are really produced by the vapours of these substances existing there, and that we may therefore safely take any small displacement of either set of lines to show a motion of the star towards or from the earth. The lines due to sodium are perhaps more intense, but are as narrow and defined as the lines D_1, D_2 in the solar spectrum; they fall, however, within a group of very fine lines; this circumstance may possibly account for the nebulous character which has been ass gned to them by Father Secchi.

The bright lines of sodium were compared with spectroscope B and eye-piece 3; they appeared to fall very slightly above the pair in the star, showing that the stellar lines had been degraded by the star's motion from the earth. The amount of displacement was estimated at about one-fifth of the distance of D_1 from D_2, which is probably rather smaller than the true amount. This estimation would give a velocity of separation of thirty-seven miles per second. At the time of observation the earth was moving from the star at about fifteen miles per second, leaving twenty-two miles to be due to the star.

When magnesium was compared, a shift in the elevation, and corresponding in extent to about the same velocity of recession, was observed; but in consequence of other lines in the star at this place, the former estimation, based on the displacement of the lines of sodium, was considered to be more satisfactory.†

Rigel.—The lines of hydrogen are strong in the spectrum of this star, and are suitable for comparison.

The line of H β is not so broad as it appears in the speculum of Sirius, but is stronger than F in the solar spectrum: this line was compared by means of spectroscope C and eye-pieces 2 and 3. The line of terrestrial hydrogen falls above the middle of the line in the star; the star is therefore receding from the earth. The velocity of recession may be estimated as rather smaller than Sirius, probably about thirty miles per second, the earth at the time of observation moving from the star with a velocity of fifteen miles, leaving about fifteen miles as due to the star. This estimate is probably rather smaller than the true velocity of the star.

Februar und März 1872, fand ich wiederum, so wie es Huggins früher gesehen hat, unzweifelhaft (2) > (3). Die relative Intensität der drei Lichtarten habe ich mehrfach in Zahlen geschätzt und erhielt z. B. in den letzten Nächten:

	März 6.	März 13.
(1)	100	100
(2)	58	63
(3)	49	52

* Phil. Trans. 1868, pp. 529-550. As a curious instance in which later methods of observations have been partially anticipated, a reference may be made to an ingenious paper in the Philosophical Transactions for 1783, vol. lxxiv., by the Rev. John Mitchell, entitled "On the means of discovering the Distance, Magnitude, &c., of the Fixed Stars, in consequence of the Diminution of the Velocity of their Light." The author suggests that by the use of a prism "we might be able to discover diminutions in the velocity of light as perhaps a hundredth, a two hundredth, a five hundredth, one even thousandth part of the whole." But he then goes on to reason on the production of this diminished velocity by the attraction produced on the material particles of light by the matter of the stars, and that the diminutions stated above would be "occasioned by spheres whose diameter should be to the sun, provided they were of the same density, in the several proportions of 70, 50, 30, and to 22 to 1 respectively."

* H. Vögel at Bothkamp seems to have repeated my observations on Sirius with the necessary care. He says (Astron. Nachr. No. 1864):—"Mit der eben beschriebenen Anordnung gelang es Herrn Dr. Lohse und mir am 22 März 1871 bei ganz vorzüglicher Luft die Nichtcoincidenz der drei Wasserstofflinien H α, H β, und H γ, der Geissler'schen Rohre mit den entsprechenden Linien des Siriusspectrums zu sehen...... mit Berücksichtigung der Geschwindigkeit der Erde zur Zeit der Beobachtung berechnet sich die Geschwindigkeit mit welcher sich Sirius von der Erde bewegt zu 10·0 Meilen in der Secunde, wogegen Procyon sich 13·8 Meilen in der Secunde von unserer Erde entfernen würde."

† I had the pleasure on one evening of showing the displacement of the lines in Sirius and α Orionis to Mr. Christie, First Assistant at the Greenwich Observatory.

Castor.—The spectra of the two component stars of this double star blend in the spectroscope into one spectrum. The line H β is rather broad, nearly as much so as the same line in the spectrum of Sirius.

The narrow line of rarefied hydrogen was compared in spectroscope B with eye-piece 3; it appeared to fall on the more refrangible side of the middle of the line in the star, leaving more of the dark line on the side towards the red. The shift seemed to be rather greater than that in Sirius, and may probably be taken at from 40 to 45 miles per second; but the earth's orbital motion was nearly 17 from the star, thus leaving about 25 miles for the apparent velocity of the star. This result rests at present on observations on one night only, but they seemed at the time to be satisfactory.

Regulus.—The line at F rather broad. The corresponding line of hydrogen falls on the more refrangible side of the middle of the dark line in the star. The air was unfavourable on all the evenings of comparison; a rough estimate gives a velocity of from 12 to 17 miles for the velocity of recession between the star and the sun.

β *and* δ *Leonis.*—These stars were compared with hydrogen; they appear to be moving from the earth, but the want of steadiness in the air prevented me from making a satisfactory estimate of their velocity. I suspected their motion to be smaller than that of Regulus.

β, γ, δ, ϵ, ζ *Ursæ Majoris.*—All these stars have similar spectra, in which the line F is strong, though there are small differences in the breadth of the line. They were compared with hydrogen, and appear to be moving from our system with about the same velocity. Probably their motion may be taken to be not far from 30 miles per second. The earth's motion at the time of observation was from 9 miles to 13 miles for these stars, leaving a probable velocity of recession of 17 to 20 miles per second. In the case of the double star ζ, the spectrum consisted of the light of both stars.

η *Ursæ Majoris* was also compared with hydrogen. I believe it shows a motion from the earth, but the observations of this star are at present less satisfactory.

α *Virginis and* α *Coronæ Borealis.*—These stars were compared with hydrogen. I suspect that they are receding, but I have not had nights sufficiently fine to enable me to make satisfactory observations of these stars.

In addition to these stars some observations (which are less satisfactory on account of the unfavourable state of the weather at the time) appear to show that the stars Procyon, Capella, and possibly Aldebaran, are moving from the earth.

The stars which follow have a motion of approach.

Arcturus.—In the spectrum of this star the lines of hydrogen, of magnesium, and of sodium are sufficiently distinct for comparison. I found the comparison could be most satisfactorily made with magnesium.

The bright lines of magnesium fall on the less refrangible side of the corresponding dark lines in the star's spectrum, showing that the star is approaching the earth. I estimated the shift at about $\frac{1}{6}$ to $\frac{1}{4}$ of the interval between Mg_2 and Mg_3; this amount of displacement would indicate a velocity of approach of 50 miles per second. To this velocity must be added the earth's orbital motion from the star of 5·25 miles per second, increasing the star's motion to 55 miles per second.

When I can get favourable weather, I hope to obtain independent estimations from the lines of sodium and of hydrogen.

α *Lyræ.*—In the spectrum of Vega the line corresponding to H β is strong and broad. Comparisons were made on several nights, but on one evening only was the air favourable. The observations are accordant in showing that the narrow bright line from a Geissler's tube falls on the less refrangible side of the middle of the line in the star, thus leaving more of the line on the side towards the violet. The estimations give a motion of approach between the earth and the star of from 40 to 50 miles per second, to which must be added 3·9 miles after the earth's motion from the star.

α *Cygni.*—The hydrogen line at F in the spectrum of this star is narrower than in the spectrum of Sirius and of α Lyræ, though probably rather broader than the same line in the solar spectrum. I have at present observations made on two evenings only, on both of which the state of the air was unfavourable, of the comparison of this line with that of terrestrial hydrogen. They give to the star a motion of approach of about 30 miles per second, which would have to be increased by 9 miles, the velocity at the time of the earth from the star.

Pollux.—The lines of magnesium and those of sodium are very distinct in the spectrum of this star. As the air was not very steady at the time of my observations, I found it more satisfactory to use for comparison the lines of magnesium, which are rather stronger than those of sodium. The three lines of magnesium appeared to be less refrangible than the corresponding dark lines in the spectrum of the star by about one-sixth of the interval from Mg_2 to Mg_3. This estimation would represent a velocity of approach equal to about 32 miles per second. The earth's motion from the star was 17·5 miles, which increases the apparent velocity of approach to 49 miles per second. On one evening only was the air favourable enough for a numerical estimate, but the observations were entered in my observatory-book as very satisfactory.

α *Ursæ Majoris.*—The spectrum of this star is very different from the spectra of the other bright stars of this constellation. The line at F is not so strong, while the lines at *b* are more distinct, and are sufficiently strong for comparison with the bright lines of magnesium. The bright lines of this metal fall on the less refrangible side of the dark lines, and show a motion of approach of from 35 to 50 miles per second. The earth's motion of 11·8 miles from the star must be allowed for.

γ *Leonis and* ϵ *Bootis.*—In both these double stars the compared spectrum due to the light of both important stars were observed. Both stars are most conveniently compared with magnesium. I do not consider my observations of these stars as quite satisfactory, but they seem to show a movement of approach; but further observations are desirable.

The stars γ *Cygni*, α *Pegasi*, γ *Pegasi*, and α *Andromedæ* were compared with hydrogen on one night only. It is probable that these stars are approaching the earth, but I wish to re-observe them before any numerical estimate is given of their motion.

γ *Cassiopeiæ*—On two nights I compared the bright lines which are present in its spectrum at C and F with the bright lines of terrestrial hydrogen. The coincidence appeared nearly perfect in spectroscope C with eye-pieces 2 and 3; but on the night of least definition I suspected a minute displacement of the bright line towards the red when compared with H β. As the earth's orbital motion from the star at the time was very small, about 3·25 miles per second, which corresponds to a shift that could not be detected in the spectroscope, it seems probable that γ Cassiopeiæ has a small motion of recession.

In the calculation of the estimated velocities the wave-lengths employed are those given by Angström in his "Recherches sur le spectre solaire," Upsal, 1868. The velocity of light was taken at 185,000 miles per second.

The velocities of approach and of recession which have been assigned to the stars in this paper represent the whole of the motion in the line of sight which exists between them and the sun. As we know that the sun is moving in space, a certain part of these observed velocities must be due to the solar motion. I have not attempted to make this correction, because, though the direction of the sun's motion seems to be satisfactorily ascertained, any estimate that can be made at present of the actual velocity with which he is advancing must rest upon suppositions, more or less arbitrary, of the average distance of stars of different magnitudes. It seems not improbable that this part of the stars' motions may be larger than would result from Otto Struve's calculations, which give, on the supposition that the average parallax of a star of the first magnitude is equal to 0″·209, a velocity but little greater than one-fourth of the earth's annual motion in its orbit.

It will be observed that, speaking generally, the stars which the spectroscope shows to be moving from the earth (Sirius, Betelgeux, Rigel, Procyon) are situated in a part of the heavens opposite to Hercules, towards which the sun is advancing; while the stars in the neighbourhood of this region, as Arcturus, Vega, α Cygni, show a motion of approach. There are in the stars already observed exceptions to this general statement; and there are some other considerations which appear to show that the sun's motion in space is not the only, or even in all cases, as it may be found, the chief cause of the observed proper motions of the stars.

There can be little doubt but that in the observed stellar movements we have to do with two other independent motions, namely, a movement common to certain groups of stars, and also a motion peculiar to each star.

Mr. Proctor has brought to light strong evidence in favour of the drift of stars in groups having a community of motion, by his graphical investigation of the proper motions of all the stars in

the catalogues of Mr. Main and Mr. Stone.* The probability of the stars being collected into such systems was early suggested by Mitchell and the elder Herschel.† One of the most remarkable instances pointed out by Mr. Proctor are the stars β, γ, δ, ϵ of the Great Bear, which have a community of proper motions.‡ while α and η of the same constellation have a proper motion in the opposite direction. Now, the spectroscopic observations show that the stars β, γ, δ, ϵ, ζ have also a common motion of recession while the star α is approaching the earth. The star η indeed appears to be moving from us, but it is too far from α to be regarded as a companion to that star.

TABLE I.—Stars moving from Sun

Star.	Compared with	Apparent motion.	Earth's motion.	Motion from sun.
Sirius	H	26 to 36	10 to 14	18 to 22
Betelgeux	Na	37	−15	22
Rigel	H	30	−15	15
Castor	H	40 to 45	−17	23 to 28
Regulus	H	30 to 35	−18	12 to 17
β Ursæ Maj.	H			
γ ,, ,,	H			
δ ,, ,,	H	30	− 9 to 13	17 to 21
ϵ ,, ,,	H			
ζ ,, ,,	H			
β Leonis	H			
δ Leonis	H			
η Ursæ Maj.	H			
α Virginis	H			
α Coronæ B.	H			
Procyon	H			
Capella	H			
Aldebaran?	Mg			
γ Cassiopeiæ	H			

TABLE II.—Stars approaching the Sun

Star.	Compared with	Apparent motion.	Earth's motion.	Motion towards sun.
Arcturus	Mg	50	+ 5	55
Vega	H	40 to 50	+39	44 to 54
α Cygni	H	30	+ 9	39
Pollux	Mg	32	+17	49
α Ursæ Maj.	Mg	35 to 50	+11	46 to 60
γ Leonis	Mg			
ϵ Bootis	Mg			
γ Cygni	H			
α Pegasi	H			
γ Pegasi?	H			
α Andromedæ	H			

Although it was not to be expected that a concurrence would always be found between the proper motions which indicate the apparent motions at right angles to the line of sight and the radial motions as discovered by the spectroscope, still it is interesting to remark that in the case of the stars Castor and Pollux, one of which is approaching and the other receding, their proper motions also are different in direction and in amount; and further, that γ Leonis, which has an opposite radial motion to α and β of the same constellation, differs from these stars in the direction of its proper motion.

* See "Preliminary Paper on certain Drifting Motions of Stars," Proc. Roy. Soc. vol. xviii, p. 169.

† Sir William Herschel writes:—"Mr. Mitchell's admirable idea of the stars being collected into systems appears to be extremely well founded, and is every day more confirmed by observations, though this does not take away the probability of many stars being still as it were solitary, or, if I may use the expression, intersystematical. . . . A star, or sun such as ours, may have a proper motion within its own system of stars; while at the same time the whole starry system to which it belongs may have another proper motion totally different in quantity and direction." Herschel further says, "and should there be found in any particular part of the heavens a concurrence of proper motions of quite a different direction, we shall then begin to form some conjectures which stars may possibly belong to ours, and which to other systems."—Phil. Trans. 1783, pp. 276, 277.

‡ Mr. Proctor, speaking of these stars, says:—"Their drift is, I think, most significant. If, in truth, the parallelism and equality of motion are to be regarded as accidental, the coincidence is one of most remarkable character. But such an interpretation can hardly be looked upon as admissible when we remember that the peculiarity is only one of a series of instances, some of which are scarcely less striking."—"Other Worlds than Ours," p. 269, and paper in Proc. Roy. Soc. vol. xviii. p. 170.

It scarcely needs remark that the difference in breadth of the line H β in different stars affords us information of the difference of density of the gas by which the lines of absorption are produced. A discussion of the observations in reference to this point, and to other considerations on the physical condition of the stars and nebulæ, I prefer to reserve for the present.

EXCURSION OF THE GEOLOGISTS' ASSOCIATION TO GUILDFORD AND CHILWORTH, JUNE 1

THE party first proceeded to examine the section of the "Woolwich and Reading Beds," just north of the station. This section was described by Mr. Prestwich in 1850 (see Quarterly Journal Geological Society, vol. vi. p. 260, fig. 6) not long after it had been exposed by the railway-cutting. A year ago it was laid bare afresh when widening the railroad; but already the slipping of the clays has obliterated some points of interest. Traces of the shell beds, with *Cyrena* and *Ostrea*, below the representatives of the "Oldhaven beds," are to be found at the base of a telegraph post, 104 yards south of the road bridge; and the underlying mottled clays, with a dip of 4° to the north, are easily recognised for about 190 yards to the south, where a small valley (about 50 yards across) has been formed by denudation out of the sand and lowest green sandy clays resting on the Chalk, which forms the northern foot of the Hogsback or Surrey range. Here the Chalk is seen to be traversed in every direction with fissures, often "slickensided," horizontally or nearly so, some empty, some filled with vein flint, and some with loamy stuff. Nodules and occasional thin laminæ of flint follow the dip of about 6° to the north, and many are in a crushed condition. Bands of marly chalk also lie on the same plane. Some Echinoderms were met with. The party then proceeded to visit the much larger excavation in the Chalk at the entrance of the railway tunnel. Here the dip, well marked by flints and marly bands, is about 12° to the north. Fossils (Sponges, Echinoderms, Inoceramus, &c.) abound in this pit. The usual chalcedonic and quartzy interiors of hollow flints attracted notice, and Prof. R. Jones drew attention to facts that seemed to him to bear evidence of flint being a pseudomorph after chalk. They next visited a quarry in the Lower Greensand, on the escarpment overlooking the pathway to Losely. In this section of those Neocomian beds known as the Bargate Stone, the waterworn sand of quartz, ironstone, lydite, and hard green silicates, is so largely mixed with calcareous fragments (the *débris* of shell beds, polyzoan reefs, &c.) that it is here and there cemented together hard and compact enough to serve as a building stone and road-metal. Mr. Meyer here directed attention to the horizon at which he obtained an unrolled tooth of *Iguanodon*, indicating the existence of this great Dinosaur at, perhaps, the latest period to which any of its remains as yet known belong. The "false-bedding" of the sands—due to the southward set of prevalent tides and currents, and the probable origin of their materials from the "old palæozoic ridge or shoal," were also studied, and the formation of the escarpment, with the correlative parallel cracks and fissures of the strata. The party then crossed the Ferry, where St. Catherine's Spring issues, beneath the hill, from a little cave in the red-orange-tinted sand. Here for thirty feet at least the Guildford gap has been found by boring to be occupied by bouldered chalk and other detritus due to the destructive, and yet conservative, agencies of nature. The soft irony beds of the Lower Greensand were next met with, and followed followed for about a mile, until a short field-lane, crossing the Gault and Upper Greensand, led into the Chalk-marl quarry below Warren Farm. Here the loss of the clay beds (Gault) from below, by their having been squeezed out along the southern side, had allowed the hard marl-rock to subside inwards and suddenly at the escarpment, and to rest at high angle (70° and more), whilst the Chalk of the hill range above dips only 5° or 6°. As the hard rock bands, here quarried for lime, are followed end-on along the strike (open to-day), the backs of lower beds form one side of this deep narrow pit; and the truncated edges of these somewhat bent and much fissured strata warn the instructed eye of the danger of standing either below them or above them, lest either rain or drought should detach their clinging surfaces from the sloping bed-plane. Large Ammonites and Nautili are the chief fossils met with here; but *Pecten Beaveri* and *Terebratula* are also found. In an old excavation in the lane *Siphonia* has been found in the representative of the Upper Greensand

which is overlain by dark-green sandy clay and Gault, turned up at a high angle (and probably squeezed out) in the breadth of a few yards, before the iron-sands are reached on returning to the hill-side. The party next came to the foot of St. Martha's Hill, or Martyrs' Hill. Before mounting this hill of sand, seamed irregularly with ironstone, some of the geologists descended the Halfpenny Hatch lane, leading down towards the East Shalford bottom, and saw a section of sand and calcareous sandstone, with a fuller's earth band and pebbly beds, similar to those in the quarry on the other (western) side of Guildford. The underground structure of South-Eastern England is connected with that of the Boulonnais, of Belgium, the Ardennes, and Westphalia; and the folds and ridges of palæozoic rocks, that in those countries bear up, either at the surface or just beneath the Chalk, or the attenuated Oolites, valuable coal-beds, are continued through, in a broad sweeping line, underneath parts of Surrey, Kent, and Sussex, until visible again near Frome, in the Bristol coal-area, in North Devon, South Wales, and the South of Ireland. The old faults and fissures affecting this linear tract of old strata had long before the Coal-period raised and depressed the lands and sea-beds; and, as a great spur of the old Scandinavian lands, this tract afforded ground for the littoral growth of the jungles that formed the coal on its oscillating borders and in its lagoons, now shut up by bars, and now losing their marsh features by influx of the sea. Succeeding ages still brought oscillations and changes, until the Jurassic seas crept over this old ridge or shoal, and the Cretaceous seas quite buried it, at first in sands and ultimately by the calcareous ooze of oceanic depths. But again another contracting crush of the earth's crust operated on the old weak lines, and the buried ridge slowly uprose, and its coating of thick strata were worn off by sea and rain, making pebbles and sand for the Lower Tertiaries; and still rising, it was at length laid bare in the Franco-Belgian and the Bristol areas; whilst our Wealden valleys of elevation, and those of Kingsclere, Shalbourn, and Pewsey, show where its uneven back approaches near the soil.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 20.—"On the 26-day Period of the Earth's Magnetic Force," by Mr. J. A. Broun, F.R.S.

Referring to the Astronomer Royal's important communication on this subject, the author confesses that, projecting his results for the horizontal force, he cannot agree in his final conclusions from them. In his paper he limits himself wholly to the observations of the horizontal force, as he has found that element, when accurately corrected for temperature, best fitted to show the period in question.

As far as the existence of a period of near 26 days is concerned, he thinks there cannot be the slightest doubt; the examination of great masses of observations has confirmed his belief; but we know nothing certainly as to its cause. It appears to be most probably connected with the sun's rotation; but in what way this may act nothing is known. The single periods show great breaks, and what may be termed *accidental* minima, in opposition to the minima belonging to the period; these accidental are connected with great disturbance, probably allied to the solar eruptions, or to causes which generally produce spots and protuberances. We might suppose that the sun during its rotation produces an action on the magnetic or electric ether in motion, which, as far as it acts on our magnet, may be supposed in greater quantity or more condensed in certain parts of the earth's orbit, and in certain years; and, as has been supposed in the case of the frequency of the solar spots, this ether may also be acted on by the planet, and produce an irregularity in the length of a few successive periods. These suppositions are made merely to show that we are perhaps not in possession of all the conditions of the problem, without which perfect exactness in the calculations is impossible.

In conclusion, he refers those interested in the subject to plate xxvii. in the Transactions of the Royal Society of Edinburgh, vol. xxii. where the daily means of horizontal force are projected for four stations on the earth's surface, all of which agree in showing the same movements, some of which have an amplitude of ·002 of the whole horizontal force (the Astronomer Royal's result for 1870 gives a *mean* value of nearly the half of this), and with intervals of about 26 days.

PARIS

Academy of Sciences, July 1.—M. M. Marie read a memoir on some general properties of the imaginary envelope of the conjugates of a plane place.—M. H. Resal communicated general equations of the movements of a solid body referred to its movable axes; and M. Montucci forwarded a note describing an experiment for the appreciation of the resistance of a sheet of brass to atmospheric pressure.—M. J. Bourget presented a memoir on the mathematical theory of the movement of a cord, one of the extremities of which possesses a given movement.—M. G. Tissandier communicated a notice of an optical phenomenon observed during a balloon ascent, describing a case in which the shadow of the balloon was thrown distinctly upon a white cloud, and surrounded by a pale elliptical halo, exhibiting the colours of the rainbow.—M. Faye communicated a letter from M. Tacchini noticing the occurrence of magnesium in the chromosphere of the sun.—M. J. A. Brown presented a note on the simultaneity of barometric variations between the tropics.—General Morin communicated an extract from a letter by M. Vinson describing a severe cyclone which followed the aurora australis of Feb. 4, 1872, at Reunion.—M. W. de Fonvielle gave an account of observations made during the ascents of the balloon "Lea," in which he refers to the above-mentioned note by M. Tissandier, giving the credit of the first observation of the halo round the shadow of balloons to Mr. Glaisher, and especially to the oscillation and rotation of balloons.—M. L. Sollier forwarded a note on the destruction of *Phylloxera vastatrix* by means of a decoction of tobacco.—M. C. Bernard presented a fourth note by M. Paul Bert, on the influence exerted by changes of barometric pressure upon the phenomena of life; and M. Wurtz communicated a third note, by M. Oré, on the question whether strychnine is to be regarded as an antidote to chloral.—M. Decaisne communicated an interesting paper by MM. Van Tieghem and Le Monnier, "On the Polymorphism of the Reproductive Organs in the mucorine genus *Mortierella*."—M. Leymerie presented a brief reply to a note by M. Garrigou on the constitution of the Pyrenees.

THURSDAY, JULY 25, 1872

THE LAST ATTACK ON DARWINISM *

THIS volume, which in bulk, general appearance, and typography bears a close resemblance to the earlier editions of the "Origin of Species," seems got up to stand by its side on the bookshelf, an ever ready antidote to the pernicious doctrines of Mr. Darwin and his supporters. After a careful perusal we must confess that it may seriously damage Mr. Darwin's reputation with those who have never read his works; but we are quite sure that no one who has studied the "Origin of Species," and been convinced of the general accuracy of its statements and conclusions, will have their convictions at all shaken by Dr. Bree's argument. As, however, it is just the work to be read by those who have only a second-hand knowledge of Mr. Darwin's works, we feel it to be a duty to call attention to the very careless manner in which the book is written,—its numerous errors, misrepresentations, and misconceptions, and its extensive use of declamation and opinion as sufficient answers to Mr. Darwin's elaborate observations, carefully selected facts, and cautious inductions.

In a work of purely adverse criticism, the first duty of an author is to quote his opponent's words with scrupulous accuracy. Yet, in the very first page of his book, Dr. Bree misquotes Dr. Hooker; at p. 3 and again at p. 9 he repeats this misquotation; and he devotes eight pages to proving that what Dr. Hooker did not say is erroneous. The quotation is from the Presidential Address at Norwich. The words actually used, and to be found in the authoritative report, are:—"So far from Natural Selection being a thing of the past, it is an accepted doctrine with *almost* every philosophical naturalist; including, it will always be understood, a considerable proportion who are not prepared to assent that it accounts for all that Mr. Darwin assigns to it." Dr. Bree omits the word *almost*, and then sets himself to convict Dr. Hooker of misrepresentation, by showing that with *some* "philosophical naturalists" it is not an accepted doctrine.

On p. 2 Dr. Bree makes a misstatement, almost equally glaring, of another author's view. He says, "And Mr. St. George Mivart has proved, and I think incontestably, that it (Natural Selection) *has not a basis of truth;*" and refers the reader to "Genesis of Species," 1871. But in this volume we find (at p. 5) the author's statement, that the object of his book is "to maintain the position that 'Natural Selection' *acts, and, indeed, must act*, but that still, in order that we may be able to account for the production of known kinds of animals and plants, it requires to be supplemented by the action of some other natural law or laws yet to be discovered."

A little further on Dr. Bree discusses Herbert Spencer's "First Principles;" and how far he is likely to elucidate that philosopher's views may be seen by the following curious blunder. At p. 48 he tries to explain to his readers what Spencer means by "the integration of matter," and quotes the following passage from his "First Principles:"—

"Every mass, from a grain of sand to a planet, radiates heat to other masses, and absorbs heat radiated by other masses; and in so far as it does the one it becomes integrated, while in so far as it does the other it becomes disintegrated."

Dr. Bree appears to have been afraid that his readers would hardly be of sufficient mental calibre to comprehend this passage. He therefore elucidates it as follows: "Integration of matter, therefore, is the absorption of heat, and heat, we are told by Tyndall, endorsed by Spencer, is 'tremulous motion'—therefore, integration of matter is the absorption of motion." We think Dr. Bree has hardly done justice to his readers by merely turning Spencer's statement topsy-turvy, and showing them that a "good rule will work both ways;" he should further have illustrated the subject by what that philosopher terms a concrete example, and explained that, in his view, water is *integrated*, when, by absorbing heat, it changes into steam, and *disintegrated* when by radiating heat it becomes solid ice!

If the supposed fallacies of such men as Hooker and Spencer, who, in Dr. Bree's opinion, are mere satellites of Darwin, are thus ruthlessly exposed, we can hardly expect the chief conspirator himself to receive much mercy. In his "Animals and Plants under Domestication," vol. ii. pp. 250-255, Mr. Darwin carefully discusses the various views as to the causes of variability, and arrives at the conclusion that variability is *not* an ultimate fact necessarily contingent on reproduction (p. 253), and that variability of every kind is directly or indirectly caused by changed conditions of life (p. 255). Dr. Bree, however, referring to the same chapter of the same work, gives his view of the writer's meaning in the following passage:—"But Mr. Darwin goes further. He says there is an inherent tendency in the constitution of the organism to vary, independent of, but modified by, its conditions." At p. 191 Dr. Bree states, as if on Mr. Darwin's authority, "that tortoise-shell cats are so coloured as a rule only in the males;" and at p. 192, that Mr. Darwin "does not believe" exactly what Mr. Darwin says he does believe. But these are only errors of the pen in the haste of argumentative composition; a less excusable mistake is made at p. 212, where, after quoting a passage from Mr. Darwin about mimicry, Dr. Bree says:—"This passage implies that an insect can imitate the organisation of another insect, by means of a knowledge that such organisation is safer from enemies than that in which nature had clothed it. A more unsound, unphilosophical, unproved, reckless statement is not to be found, &c. &c. . . . It is only just to say that the above theory did not originate with Mr. Darwin. It is the *sole production* of the fertile brain of *Mr. Wallace.*" Here we have a misrepresentation and a misstatement. No expression of Mr. Darwin or myself can be taken to mean that we believed in a voluntary knowing imitation of the organisation of one insect by another. In my article on "Mimicry" I have expressly disclaimed this view. As to the latter part of the quotation, the first words of Mr. Darwin's paragraph headed "Mimicry," and which Dr. Bree must have had before his eyes, are:—"This principle was first made clear in an admirable paper by *Mr. Bates!*" A little farther on, my

* "An Exposition of Fallacies in the Hypothesis of Mr. Darwin." By C. R. Bree, M.D., F.Z.S, Senior Physician to the Essex and Colchester Hospital. (London: Longmans, Green, and Co., 1872.)

theory of birds' nests and the colour of female birds is noticed with strong disapproval; and a crushing array of facts is adduced as being opposed to my statement that "when both sexes are coloured in a strikingly conspicuous manner the nest is of such a nature as to conceal the sitting bird." The whitethroat, thrush, snipe, skylark, and hedge-sparrow are adduced as opposed to my views; but as they must all be coloured in a *strikingly conspicuous* manner if they are to be of any use to Dr. Bree or his hypothetical schoolboy, the reason why they are cited remains a mystery to me. Two pages farther on we have more misquotations or blunders. At p. 229 we are told that Nitzsch's "feather tracts" are those parts of the body which have the skin uncovered! while at p. 230 we find that it is the brilliant rays *absorbed* by feathers that produce the vivid, varied, and beautiful colouring of birds! At p. 259 it is stated that "inconceivably minute changes" are alone utilised by natural selection—a misrepresentation which no word of mine or Mr. Darwin's will justify. At p. 261 we have this passage:—"Mr. Wallace adopts Mr. Darwin's view, that there is no such thing as instinct at all, in the sense in which we understand the word. He considers it the 'result of small contingent consequences, as produced by natural selection.'" As the "he" in this sentence appears to refer to Mr. Wallace, and the last ten words are given as a quotation, I felt rather ashamed of myself for writing what I could not the least understand. But a careful examination of my paper shows me that I have said nothing about the "result of contingent consequences;" neither can I find anything of the kind in Mr. Darwin's writings on "instinct." We must pass it over, therefore, as one of the ingenious paraphrases by which Dr. Bree endeavours to elucidate a difficult subject.

In a large folded frontispiece we have "The Descent of Man, after Darwin's Theory," and this is explained at p. 325; but here, too, Mr. Darwin has not been read aright, for "man's ancient ancestor, with cocked ears, tail, prehensile feet, both sexes bearded and hirsute, males with great canine teeth," is placed between Marsupials and Lemurs, whereas Darwin places it after the origin of the catarrhine monkeys, in fact, at Fig. 15 of Dr. Bree's diagram. Our author makes a great point of this, and says:—"From such a Darwinian creation were descended the lowest of the quadrumana, the lemurs."

At p. 331 we have another of our author's enigmatical sentences:—"If an optician makes an object-glass, he does so in reference to the objective, the lens." I had previously imagined that the objective *was* the object-glass; but at p. 351 I was still more puzzled by reference to the "final law of the pendulum" and the "final law of the screw"—two things I had never before heard of.

We think we have now shown that this book contains so large a number of errors, misrepresentations, and misconceptions as to render it quite untrustworthy. We proceed to give a few instances of the author's copious use of declamation, assertion, and opinion, of doubtful facts and illogical arguments.

Of declamation and assertion we have an abundance, the following being a favourable specimen:—"The system of Darwin is eminently illogical, and must fall. It is an hypothesis which draws large but unsound deductions from the rare and abnormal deviations, leaving the real field untouched and unexplored. It is founded upon the exceptions, not the rules of nature. It is utterly opposed to design, to the teachings of animal mechanics, to the grand and beautiful and everlasting proofs upon which the teleologist loves to dwell. It is a cold, unsound, unphilosophic, degrading system of assumed probabilities, which, if true, would be ten times more wonderful than anything assumed or believed by the most strict and rigid disciple of special creation. Nay, still further, if proved in every point to be true, it would still leave the fact of special creation in all its wonderful mystery. The organic cannot be formed from the inorganic; nor could the organic, if it were so formed, be endowed by any physical force with the laws and properties of life. Go on still in speculation, and I ask, Whence the inorganic—its beginning, its ending, its grand and inexplicable laws, which the physicist in vain attempts to correlate with the vital? Whence gravitation, and what? the sidereal system and its movements? the Spirit that breathes through illimitable space, and lives through an eternity of time?"

A large portion of the volume is occupied with quotations from Agassiz, Haughton, Flourens, Owen, and other opponents of Darwinism; and Dr. Bree complains that these authors have hardly been noticed and not replied to by Darwin or his supporters. But the reason of this is explained in the pages of the present work (where we may suppose their best passages are quoted), by the almost entire absence of argument directed to the essential points of Mr. Darwin's theories, and the immense preponderance of loose assertions, in support of which no evidence is given. Thus, Agassiz asserts that "the differences" among domestic animals "are not of the same kind as the differences we observe among wild animals;" that "the differences we observe among wild animals are the result of a *creative power;*" that "domestication *never* produces forms which are self-perpetuating;" that "*at all times* the world has been inhabited by as great a diversity of animals as exists now;" and other similar assertions, almost all of which are controverted by accumulated facts in the works of Mr. Darwin. Chapter xxviii. is entirely devoted to an account of Agassiz's views of design, and supposed *proofs* of a creative mind at work in every step of the development of a group of animals. The facts will appear to most naturalists thoroughly consistent with the theory of evolution and that of natural selection; while the arguments involve a view of the Deity which most philosophical thinkers will find it hard to accept. Agassiz compares the Creator to an engineer, and speaks of Him as "*constantly* and *thoughtfully working* among the *complicated structures* that He has made." This idea is not that of an *omniscient* Creator, but of some inferior being with an intellect vastly superior to man's, but yet limited. "*Thoughtfully working*" implies effort to understand and overcome difficulties; whereas *thought* at all, as we think, is utterly opposed to the conception of omniscience.

Another chapter is devoted to Prof. Haughton's theory of "Least Action in Nature;" and here, again, all the established facts are perfectly consistent with, and almost necessary deductions from, evolution and natural selec-

tion. But it is the mere wide general assertions which Dr. Bree quotes with greatest approval as destructive of Darwinism. Thus: "There is no evidence in nature of birds with imperfect wings; no proof of a succession of blunders before perfection was attained. All is perfect, and all was always perfect." And again: "In every arrangement of bones, muscles, joints, and parts of animals, the motion *must* be such as it would be on the hypothesis that the muscles were a living, intelligent thing, trying to save itself trouble." This last may be true, but it is certainly not necessarily true; and as to imperfect wings, what are those of the Cassowary and Apteryx, which have no known function whatever?

The article of M. Flourens against Darwin is given in an appendix, and his facts as to the crossing of quadrupeds are said to be absolutely fatal to the whole theory of natural selection. But these facts are of a very imperfect and scanty character, and are almost wholly negative; and they are fully noticed in Mr. Darwin's elaborate discussion of the difficult question of hybridity, although Dr. Bree assures his readers that these facts were "never contradicted or *even noticed by Mr. Darwin!*" Under the heading "Flourens," in the index to "Animals and Plants under Domestication," are four references, and the works, "Longévité Humaine" and "De l'Instinct," are referred to; while Dr. Bree himself seems to be unaware of the existence of anything but the "Criticism on Darwin," which has been long ago most admirably answered by Prof. Huxley.

We will now give a few examples of the facts and arguments adduced by Dr. Bree himself. At p. 90, he tells us that Mr. Darwin "has given figures of different sized skulls and jaw-bones, scapulæ and clavicles (of pigeons), differing just as much from each other as the same bones in different sized Englishmen would do; and nothing more!" And on the next page he assures us that a Colchester pigeon-fancier told him, that if he allowed his short-beaked tumblers to fly out of doors they would revert to a state of nature, and that, *in a few weeks*, the beautiful small beaks would be as long and as coarse as those of any other bird! On which Dr. Bree triumphantly remarks—"Of course they would." At p. 131 he tells us, that although young song birds will learn other birds' notes with which they may be associated, yet *if kept quite alone* they will sing their own natural song, "*as several who have tried the experiment assure me.*" This is directly opposed to the experiments on this very point of Daines Barrington, quoted by me in "Contributions to the Theory of Natural Selection," 2nd Ed. p. 221, and it would therefore have been a valuable contribution to our knowledge of this difficult subject if the experiments alluded to had been given in detail, not vaguely referred to. At p. 143 it is stated that the bees' cell "is one of the finest examples in nature of what is termed the principle of 'least action;' that is to say, the greatest amount of space is gained by the least amount of material." This is certainly not true, for the cell being suspended from *the top* and *equally thick throughout*, must be too strong at bottom if strong enough at top. There is therefore waste of material. This objection was published nine years ago, in the "Annals of Natural History" for October 1863, and it has never been answered.

On the imperfection of the geological record Dr. Bree is very strong. He says that Mr. Darwin "asks us to imagine that an ape-like man became evolved in the lower tertiaries, the remains of which or of his descendants have never been discovered. Such a demand upon the credulity of mankind was never, I believe, before seriously made, unless we were told that geese were transmuted barnacles" (p. 180). This is, of course, a sufficient answer to Sir Charles Lyell's careful investigation of the subject, and especially to his most suggestive table of old fossil mammals, given in the twentieth chapter of his "Elements of Geology."

Mr. Mivart and Prof. Owen are both applauded so far as they oppose Darwin, but as both of them believe in some form of development, they are, in Dr. Bree's opinion, almost equally involved in error. Mr. Mivart's doctrine of evolution, he thinks, cannot stand, and "looks too much like Mr. Tegetmeir's pigeons, made to order." It is, however, no doubt offered with the best intentions, "as a means of reconciling scientific and religious thought,"—"two lines which, Mr. Spencer remarks, are running parallel *and* gradually approaching each other!" (We doubt the accuracy of this quotation from Mr. Spencer, but we are near the end of the book and have learnt not to expect accuracy.) Prof. Owen has, in Dr. Bree's humble opinion, "surrendered the outposts of our defence to the believers in the Darwinian hypothesis." As to Sir Charles Lyell, the charm of his works is gone for Dr. Bree, and he reflects with melancholy what the future will think of the great geologist's transmutation of thought, and with regret that such a man could, "in the maturity of his age and fame, have forsaken the 'principles' of his youth, of his manhood, and of his prime." The researches of M. Gaudry in Greece are of no use whatever; for the various forms of elephant, rhinoceros, horse, and pig, which he and Sir Charles Lyell believe to be intermediate forms, differ no more from one another than do English from Americans, and only prove a "slight variation!"

These are the kind of observations, this the kind of reasoning, by which Dr. Bree thinks to stem the tide of belief in Darwinism. At p. 269, Prof. Huxley is severely criticised for having written the following passage: "The mixture of ignorance and insolence which *at first* characterised a large proportion of the attacks with which Mr. Darwin was assailed, is no longer the sad distinction of anti-Darwinian criticism." This, Dr. Bree, with his usual curious logic, asserts is manifestly untrue, *because* some of the highest men in science, such as Agassiz, Flourens, Owen, Haughton, &c., oppose Darwinism. Why then did Dr. Bree not let well alone—leave the battle in the hands of these redoubted champions, and not give Prof. Huxley the opportunity of retracting his statement, on the ground that although the *insolence* of the first opponents of Darwinism may have vanished, their *ignorance* has returned?

In conclusion, I must again repeat that the only reason for devoting so much space to a book so little worthy of its title or its author, is the wish to warn such as are not well acquainted with Mr. Darwin's works from implicitly relying either on Dr. Bree's facts and arguments, or on the accuracy of his representation of those of Mr. Darwin and his supporters.

ALFRED R. WALLACE

OUR BOOK SHELF

Experimental Chemistry. Founded on the work of Dr. J. A. Stöckhardt. By C. W. Heaton, F.C.S. (London: Bell and Daldy.)

MANY students of chemistry have had reason to be grateful to Dr. Stöckhardt for his work on the Principles of Chemistry. For many years it was almost the only representative of its class; for it enabled students to acquire a considerable and useful knowledge of chemistry by teaching them to work experimentally at the subject, instead of merely reading about it. One of the great merits of his book, and which also belongs to the volume now under consideration, is that, although the number of experiments described is large and well selected, yet they do not necessarily require anything but extremely simple apparatus. This work, therefore, we believe will be found useful to a numerous and increasing class of students. who, though hindered by limited means and want of opportunity, wish to acquire some knowledge of chemistry.

The work is divided into four parts: the first treating of the General Principles; the second on the non-metallic elements; the third on the metals; and the fourth on Organic Chemistry. With the commencement of Part I. we confessed we were rather startled. The student is at once taken into a sort of half discussion as to whether matter has any existence or not, and the conclusion come to is that the problem will probably be for ever in dispute. This to a young beginner would scarcely impress him with the definite and unchangeable facts of Physical and Chemical Science.

Part I., on General Principles, is, we think, too advanced and complicated for the class of students by whom it is likely to be used. In fact, we should imagine that a student commencing the book and working by himself would find this part very up-hill work. For instance, before having studied any of the properties of the elements, he has to become acquainted with the various methods of fixing the atomic weights, the classification by atomicity, variations of atomicity, isomorphism, &c. In our opinion it would be almost better for a student to commence at the second part, that is, with the study of the non-metallic elements, in doing this, however, some little reference to Part I. would be necessary for the explanation of the meaning of symbols, &c., and he might then return to the complete study of Part I. The first part contains a number of definitions, several of which are not so good as they might be. It is said, for instance, that in a mixture the properties of the different ingredients are always perceptible. Gunpowder is given as an instance of a mixture; but in this the yellow colour of the sulphur and the white colour of the potassic nitrate are certainly not perceptible. Again, the definition of an acid is the following:—"An acid is composed of hydrogen with one of those radicles (p. 86) which are called acid radicles. The hydrogen can be replaced by metals, in which case one of the compounds called salts is formed. Acids redden litmus, and are commonly sour." On referring to p. 86, the exact definition of an acid radicle is not to be found; it is, as nearly as can be expressed, according to the author's ideas, the residue of an acid from which the hydrogen is abstracted. The definition of an acid, then, seems to be a body that contains hydrogen replaceable by metals, which is sometimes sour and reddens litmus. Surely definitions of a rather more definite and complete character might have been selected. Further in the book (p. 298) the author thinks it is often more convenient to regard the inorganic acids as hydrates, that is containing the radicle hydroxyl (HO), and of course uses this radicle throughout the organic acids. If the student accepts the two definitions he will have a double set of radicles, which would probably lead to much confusion.

The second part of the book is devoted to the non-metallic elements, the properties of which are studied by means of simple and instructive experiments, which are generally well described; the same is also the case with the next part, on the metals, and we then pass to the organic section of the work.

The field of Organic Chemistry is now so large that in the small space here devoted to it, a brief description only can be given of some of the more important compounds. It is also difficult in this section to arrange experiments which can easily be performed by students. It is thus necessary to confine the description of such classes of substances as the alcohols, the aldehydes, acids, haloid ethers, &c., to a very few pages. The arrangement, too, is peculiar, the experimental part of the organic work beginning with the study of cellulin, starch, sugar, &c., passing afterwards to the study of the more simple compounds, such as ethylic alcohol, acetic acid, &c.,—which seems rather like reversing the order of things. In a subsequent edition it would, perhaps, be better to adopt the modern system of classification, which would probably give the student a far better and more comprehensive knowledge of the subject. The book is, on the whole, one which, with a little reservation, can be safely recommended to students who wish to study Chemistry in the experimental way rather than simply to cram it up by reading. There is some room for improvement in the woodcuts, which in some instances are not artistic, and might be replaced by engravings of more modern and convenient apparatus.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Ocean Currents

I HAVE just read Mr. Ferrel's letter (NATURE, June 13), in which he refers to mine of April 25, and the proof therein adduced by me to show the physical impossibility of oceanic circulation being the result of differences of specific gravity. Unless Mr. Ferrel means (and I hardly think he does) that six foot-pounds of energy can perform 9,025 foot-pounds of work provided only sufficient time be allowed in which to perform that work, then I do not suppose there is any reader who may have glanced over my article on the subject who will not readily admit that Mr. Ferrel's reasoning has no direct bearing whatever on my argument.

The slope from the equator to latitude 60° is six feet. The total amount of work which gravity can perform upon a pound of water in carrying it down this slope is, of course, six foot-pounds. And this holds equally true whether the pound of water moves down the slope in, say one month, or takes 1,000 years to perform the journey; because the amount of work performed by gravity depends not upon the time which a body takes in descending, but upon the distance through which the body descends. In the present case six feet is the distance, consequently six foot-pounds is the amount of work performed upon the pound of water in its passage down the slope from the equator to lat. 60°.

Mr. Ferrel assumes that the velocity of the general movement of the water advocated by Dr. Carpenter does not exceed one mile per day, and that consequently the resistance to motion must be small. Undoubtedly the slower the motion the less the resistance; but so far as the argument under consideration is concerned, it is a matter of indifference whether we suppose the velocity of the water to be a mile per minute, a mile per day, or only a mile in 1,000,000 years; because it is found that when the water from the equatorial regions reaches, say, lat. 60°, it, as a matter of fact, is not moving eastwards relatively to the earth's surface with a velocity of several hundreds of feet per second, but with a velocity of only a few feet per second, perhaps not more than three feet at the utmost. In this case the water has lost 760 feet per second of velocity which it possessed when it left the equator. Each pound of water has therefore lost 9,025 foot pounds of energy. What has become of all this energy? It has all been consumed in overcoming resistance during the motion of the water from the equator to lat. 60°. But, be it observed, it has

been consumed, not in overcoming resistance to the poleward motion of the water, but in overcoming the resistance to eastward motion. The energy consumed is deflecting energy, not impelling energy.

According to Dr. Carpenter's theory the pound of water has in virtue of gravity only six foot-pounds of energy to carry it from the equator to lat. 60° against all the resistances to its poleward motion; but it so happens that before the water reaches lat. 60° no less than 9,025 foot-pounds of energy is consumed in overcoming resistance to eastward motion. But if it requires 9,025 foot-pounds of energy to overcome the resistance to eastward motion, how is it possible that Dr. Carpenter's six foot-pounds of energy can overcome the resistance to the poleward motion? The velocity of the motion of the water polewards is as great as, if not greater than, the velocity of the motion eastwards, consequently the resistance to the motion of the water poleward must be as great as the resistance to the motion eastward. But if so, then the work of the resistances to poleward motion is 1,500 times greater than the work of gravity. The work of gravity being only six foot-pounds, whereas the work of the resistances is 9,025 foot-pounds.

One of two things must therefore follow as a necessary consequence: (1) either the work of the resistances to poleward motion is 1,500 times greater than the work of gravity, or (2) the work of the resistances to poleward motion is 1,500 times less than the work of the resistances to eastward motion. But either conclusion is equally fatal to the gravitation theory.

It seems to me that until the advocates of this theory manage to escape from this dilemma, it is needless to argue further on the matter. For, unless it can be shown that the work of the resistances is not greater than the work of gravity, the much disputed question as to whether or not difference of specific gravity can be the cause of a *general* interchange of equatorial and polar water must be regarded as finally settled in the negative.

I cannot help thinking but that Mr. Ferrel is misled by his supposed analogy between a slope produced by the influence of the attraction of the moon and that produced by difference of specific gravity. Although a slope of 9 feet in a quadrant resulting from difference of specific gravity is insufficient to produce motion of the water, nevertheless, the sea will easily regain its level after the attractive force of the moon is withdrawn, even though the height to which the surface of the ocean is raised may not exceed a single inch. The reason of the difference in the two cases must be obvious to any one who will reflect on the matter. I have already in my paper in the Phil. Mag. for Oct. 1871 alluded to this reason, and will have occasion again to refer to it at greater length.

I may notice that by a typographical error in my article the velocity of rotation at lat. 60° was stated to be 773 feet per second instead of 763 feet per second.

Edinburgh, July 18 JAMES CROLL

The Melbourne Telescope

MR. ELLERY has been so good as to send me an enlargement of the lunar photograph taken with the great Melbourne telescope, to which you allude at p. 228, No. 142 of your Journal. This picture, Mr. Ellery tells me, was taken on the second evening of trial; it is very beautiful, although not so *critically* sharp as several I have obtained with my Newtonian equatorial of 13 in. aperture, and a little more than 10 ft. focal length. This sharpness, however, is a mere question of the shadiness of the atmosphere; and I feel persuaded that pictures will be taken with the Melbourne telescope far surpassing any hitherto procured. In my telescope the focal image varies from 1 in. to $1\frac{2}{10}$ in. in diameter, according to the distance of the moon from the earth. The primary picture of the Melbourne telescope (an enlargement of which has been sent to me) is $3\frac{3}{10}$ in. in diameter; hence the structure of the collodion and minute defects in it are of much less importance than when smaller instruments are used.

The employment of the great Melbourne telescope for astronomical photography cannot fail to be of great advantage to astronomy, and I should be very glad to see a similar instrument at work in England, notwithstanding its too much abused climate.

WARREN DE LA RUE

P.S.—As soon as the Melbourne picture has been mounted and protected, I will place it in the Astronomical Society's rooms for inspection.

On the Rigidity of the Earth and the Liquidity of Lavas.

IN his letter upon the Rigidity of the Earth and the Liquidity of Lavas in the number of NATURE for July 11, Dr. Sterry Hunt has replied to my challenge to propose an explanation of the connection between mountain ranges and trains of volcanoes consistent with a rigid globe, other than that to which I refer it, viz. the production of fusion through a diminution of pressure due to the partial support of the mountains by the lateral thrust which has upraised them. Dr. Hunt suggests that liquefaction may take place beneath such ranges, through *increased* pressure promoting the liquefaction of the water-impregnated mass; and quotes the late Archdeacon Pratt as maintaining the existence of a greater pressure beneath mountain ranges.

In reply, I may be allowed to ask Dr. Hunt for a reference to such an expression of Pratt's opinion. I cannot call to mind any passage of his to that effect. The result of his calculations of the attraction of the Himalayas upon the plumb-line showed that they do not attract so much as they ought to do, and he explained this by supposing a deficiency of matter beneath the mountains. His own explanation of the phenomena, as given in the fourth edition of his Theory of the Earth, finished very shortly before his lamented death, is, "that the varieties we see in mountains and plains and ocean beds in the earth's surface, have arisen from the earth having been once a fluid or semifluid mass, and that in solidifying the mass has contracted unequally, so as to form hollows where the contraction has been greatest, into which water flowed and formed seas and oceans, and to leave high table-lands and mountain-ranges where the contra tion has been less." (He speaks here of contraction in the vertical direction) A geologist will, I suppose, receive this as a very incomplete explanation; but the material point is that the Archdeacon was led to adopt it because he had discovered a deficiency of matter beneath the Himalayas. This seems incompatible with Dr. Hunt's view (both with regard to Pratt's opinion on the subject, and with regard to the fact itself) that there is an increased pressure beneath mountain ranges.

It will now appear that my "speculation" upon the origin of volcanic action was suggested by the proved deficiency of matter, and consequently probable diminution of pressure; and not that the idea of diminished pressure was invented to account for volcanic action. I have merely proposed a connection between lateral pressure and diminished density which seems most natural, namely, that the same pressure which upraised the mountains continues partially to support them. And I cannot see how it can do otherwise. For the abutments of the mountains having approached by contraction of the crust, cannot again recede without expansion, which cannot take place. Dr. Hunt's view of the liquefaction of lavas, to my mind, requires explanation. Admitting that pressure promotes aqueous liquefaction in heated rocks, when rocks so liquefied began to rise in a volcanic mass, would they not be brought under diminished pressure, and would they not become immediately solidified, so that they could not reach the surface in a fluid state?

Moreover, since liquefaction, according to this view, is increased by pressure, the interior parts of the earth being under greater pressure than the more superficial strata, ought, at least to that depth where water is present, to be more liquid, and this would be incompatible with the supposition of a rigid globe which Dr. Hunt favours.

Harlton, Cambridge O. FISHER

The Method of Least Squares

WILL you allow me to call the attention of Mr. J. W. L. Glaisher to the following sentence from Encke, Berliner Jahrbuch 1853, p. 311. "Ich werde mir deshalb erlauben, völlig dem Gange den Lagrange genommen hat folgend, wie könnte man sich erdreisten, bei der ungemeinen Klarheit, Einfachheit und Tiefe des grossen Meisters, eine irgend bedeutende Änderung vorzunehmen, den Theil der Abhandlung hier wiederzugeben, welcher den Beweis für das arithmetische Mittel enthält, und selbst Sätze, die im Grunde schon die Methode der kleinsten Quadrate in sich begreifen." Also to article 17, Corollary, of the Memoir of Lagrange.

This is not the place to discuss the doctrine of the Method of Least Squares; but I may say that in my judgment the method rests on the assumption of the principle of the arithmetical mean, an assumption which is justified by an universal experience.

Having made this assumption, the rule that the sum of the squares of the remaining errors is a minimum follows very simply: *vide* the late Memoir of Hansen, art. 3.

With regard to the practical application of the Method of Least Squares, I think the whole honour of its introduction belongs to Gauss. The rules which he and his scholar Encke have given for the application of the method, and for executing the numerical operations, are so complete and perfect that but little more can be desired.

Washington, July 4 ASAPH HALL

Solar Rainbow

ON the 10th instant at about half-past seven in the evening I saw part of a well-defined rainbow about 5° west of the zenith, the convexity of the bow towards the setting sun, which at the time was about 3° above the horizon. Light clouds were passing beneath the bow. There was no rain.

Brighton, July 15 GEORGE DINNOW

Hive Bees *v.* Mechanism

I HAVE never followed Huber through his wonderful researches into the astounding working proceedings of hive bees—that elder Huber, who, by the way, aided by so admirable a spouse, brought his researches to so successful an issue, notwithstanding his blindness. Hence my excuse, if what I attempt to describe as being original to my own sense of observation, prove not so to others. I think it is conceded universally that amongst other leguminous plants peas have ever been secure from cross fertilisation, one variety with the other, in so far as natural influences, insect agency, &c., are concerned. Our stocks of garden peas, though known to run weedy and grow inferior when cultivated too long upon one kind of soil, very rarely, if ever, sport or vary as other plants placed in juxtaposition of species, especially varieties, are known to do. So decidedly has this fact been confirmed, that invariably sweet peas, even when it is desirable to grow them true to name, are sown in rows, side by side, whites, scarlets, blues, &c., with the utmost impunity. And this is wholly owing to the fact that the floral envelopes are so securely wrapped around the pistil and the stamens, that these parts cannot be reached without the exertion of more power than the strength bees and similar winged insects are supposed ordinarily to possess; unless, indeed, mechanism be called to their aid—a science in itself, but which, nevertheless, has been resorted to in the instance to which I would direct attention. Here then the hive-bees methodically bare the stamens by sheer mechanical force, and rob each of its load of pollen by sense of touch alone. And this they do in this wise. Alighting on the *alæ* or "wings" of each bloom, they first of all press their heads up under the base of that part of the papilionaceous corolla called the "standard," or *vexillum*, and extract what nectar they find. Then, with their little heads firmly pressed therein, and holding fast by the four fore legs, they exert their power, thus artificially contrived, by treading down both the aforesaid wings and the "keel," or *carina*, which so securely envelopes the sexual organs, that they protrude, so that the anthers are laid bare, when they generally rub the pollen off the stamens on to their hairy bellies, only occasionally using one hinder leg to aid them. It will be seen that they do this with their hinder legs and body, at a time when their heads are entirely hidden from view. I have tested these parts in regard to the pressure needed to disclose the pollen thus, and find that a pressure of half to three quarter ounce is necessary; and computing the weight of an individual bee to be about the sixteenth of an ounce, we see what an amount of power must be exerted in this hind-before, or blindfold manner, by these interesting little creatures.

I should add, however, though I have been a selecter of sweet peas for more than a dozen years in other parts of the country, as the selection sold by some seedsmen with my signature attached confirms, I nevertheless have not previously believed in any power possessed by insect agency to thus destroy selections. Here, at Valentines, however, being only seven miles from London, it would appear that the bees, like town sparrows, are unusually "wise in their generation," and that, owing to scarcity of honey-yielding materials, they are driven to such wonderful feats as I have explained.

WILLIAM EARLEY

The Gardens, Valentines

The Red Rocks

IF the peroxide of iron was deposited (as in the Swedish lakes) as brown hydrous peroxide, and if long boiling in the laboratory may be considered analogous to evaporation in an inland sea, then it would appear from the following extract from Watts's "Dictionary of Chemistry" that there is no difficulty in accounting for the colour of the red rocks:—

"A remarkable insoluble modification of ferric hydrate is produced by boiling the ordinary yellow hydrate to $2\,Fe_2O_3\,3\,H_2O$ (precipitated from the chloride by ammonia) in water for seven or eight hours. The colour then changes from ochre-yellow to brick-red, and the hydrate thus altered is scarcely acted upon by strong boiling nitric acid, and but very slowly by hydrochloric acid. In acetic acid, or dilute nitric or hydrochloric acid it dissolves, forming a red liquid, which is clear by transmitted, but turbid by reflected light; is precipitated by the smallest quantity of an alkali salt or a sulphate; and on addition of strong nitric or hydrochloric acid, yields a red granular precipitate, which redissolves on diluting the liquid with water."

The change of colour from brown to red is readily obtained by boiling the hydrate in a flask for several hours, as described above. The change is gradual, and before becoming finally red the precipitate is of a chocolate colour, corresponding with that sometimes observed in the red sandstones.

Small pieces of white sandstone, introduced into the flask during the boiling, are of course coloured red, and resemble red sandstone when taken out and dried. R. D. P.

Instantaneousness of Lightning

DURING a recent night thunderstorm I got out my colour-top, with the usual disc of so-called primary colours arranged to blend into grey or white on rotation, in order to show to my children the instantaneousness of the lightning, and that by its light the disc would, as I had no doubt, appear stationary in one or several successive positions according to the character of the flash, as it does by the light of an ordinary electric spark from a Leyden jar or induction coil. On trying the experiment, however, by turning the disc (about forty times in a second) at a window in a dark room opposite to the cloud in and from which the discharges were taking place, I found that this was only very partially the case. When the direct stroke was actually visible, or only slightly veiled by cloud, the effect I looked for was produced, the bands of colour standing out clear and apparently motionless; but at other times during the apparently (to the eye) prolonged flash, the colours blended so as to indicate a continuous fainter light in addition to the occasional instantaneous appearance of definite colour and form due to the intermittent light of the discharge. Of course I satisfied myself that there was no other light to account for this, the night and the room being very dark in the intervals of the flashes, and I repeated the experiment in another night storm (on the 11th) with just the same result. The effect appears to be due to the retention of light in the cloud by phosphorescence, and, so far as I can find on inquiry, does not seem to have been noticed before.

If my view is correct, it would explain the fact that distant lightning at night, when no cloud is in sight, is apparently so much sharper than when nearer.

A propos to the subject, a letter to the *Times* describing the storm of the 11th inst., speaks of the lightning "flickering with a perceptible rustle"—a curious instance of transference of impression from one sense to another, the visual sensation of flickering being exactly analogous to the auditory sensation of rustling. B. W. SMITH

Hampstead, July 20

Severe Thunderstorm

A HEAVY thunderstorm passed over this neighbourhood this afternoon. One of the flashes was followed by a smart "snap" like that of the discharge of a large Leyden jar, or the explosion of a heavy percussion cap. The interval between this noise and the crash of the thunder was about half or three-quarters of a second. I have not unfrequently noticed a hissing noise immediately preceding a violent clap of thunder, but never anything so distinctly resembling the sound of the ordinary electric spark.

Willesden Lane, Kilburn, July 23

TECHNICAL EDUCATION

ON Saturday last a meeting was held at the rooms of the Society of Arts, of scientific men and others interested in the promotion of technical education among the working classes, and especially among the skilled artisans of this country. The chair was taken by H.R.H. Prince Arthur, who showed in the remarks which he addressed to the meeting an admirable appreciation of the extreme value of the subject to the future prosperity of the country. After the Secretary of the Society of Arts had explained the proposal of Captain Donnelly that the Society should establish technological examinations for the purpose of testing the practical knowledge and skill required in the application of the scientific principles involved in each art and manufacture, H.R.H. said:—

"The Society of Arts are endeavouring to encourage among those who are practically employed in various industries the study of art, and an accurate knowledge of its application in each branch of manufacture. The Society will not, however, attempt to teach the practice of those arts. Their object is rather to lay a sound foundation of all the principles on which those practices may be carried out to the best advantage. The Society wish and desire to give certificates, prizes, and scholarships to those who show that to practical skill as workmen they have added an accurate knowledge of natural principles in those matters. I am certain the necessity and advantage of combining scientific principles with practice will be seen by all. I only wonder that we are but just beginning to undertake this task. The machinery for these technological examinations already exists, and, in fact, the skeleton of industrial universities is ready to our hands. What we now require is funds to clothe it with and give it life, and to enable it to carry out its work—that is, to obtain sufficient prizes to encourage and reward the deserving youth of this country. If others would only do what Sir Joseph Whitworth has done by his noble endowment for mechanical engineering, we might soon hope to see our most sanguine expectations realised."

Little by little the country is gradually waking up to understanding the principles on which alone its future greatness as a manufacturing nation can rest, Many will probably echo H.R.H.'s wonder that "we are but just beginning to undertake this task."

VOLCANOES OF CENTRAL FRANCE

THE conduct of the war against the Goths having brought Procopius into Campania, he is thus led to give an account of Vesuvius. In the text before me the mountain is called Bebios, and ash is said to have fallen at Byzantium; but undoubtedly Vesuvius is meant, and there seem to be good reasons for suspecting that "Byzantium" should be "Beneventum." Both Besuios (= Vesuios) and Beneventum could be so written as easily to be mistaken for the names now in the text. I cannot indeed pretend to say when, I must leave that to the critics.

Procopius, "De Bello Gothico," l. ii. c. 4: "At that time Mount Vesuvius was roaring, but there was no eruption; however, in consequence of the roaring, an eruption was confidently expected and the surrounding population were in great fear. This mountain is about seventy stadii from Naples, bearing northwards from that place (*τετραμμ-ένον αὐτῇ πρὸς Βορρᾶν ἄνεμον*). [The real bearing is about 10° S. of E. Is he confounding Naples with Stabiæ, where Pliny died?]* It is naturally escarped,—wide-spreading below, but the top steep and very rugged; and on the summit of Vesuvius, in the centre, there is a cavern, which appears to be remarkably deep, and it would seem as if it extended quite to the extremities (*ἔσχατα*) of the mountain; and any one who is bold enough to look down may see fire in it. It is of no consequence to the inhabitants when no flame is seen above it; but when the mountain sends forth an explosive roaring it generally happens that not long afterwards a vast quantity of dust is thrown up, and if this destructive shower meets a traveller on the road he can by no means escape with his life; and if it descends on houses, they fall, crushed down by the mass of ash; and if a violent wind happens to be blowing, the ash is carried to a great height, out of people's sight, and is transported wherever the wind may carry it, and it may fall in some country at a very great distance. And they say that formerly, when it fell in Byzantium [*qu.* Beneventum?], the people there were so alarmed that they have made it a rule (*ἔγνωσαν*) in general assembly from that day to this to propitiate the deity by yearly supplications (*λιταῖς*). At another time (they say) it fell in Tripolis in Lybia. And they say that this roaring first (?) took place a hundred or more years ago, and that latterly it occurred much more frequently, but with decreasing violence.* They say, too, that when Vesuvius happens to eject this dust, the country where it falls is sure to produce abundant crops. On this mountain especially, beyond all others, the air is very light, and highly conducive to health, and time out of mind medical men have unhesitatingly sent thither their consumptive patients. Such, in the main, are the circumstances in connection with Vesuvius."

Vesuvius lies about 40° 47′ N. by 14° 26′ E., Byzantium about 41° N. by 28° 59′ E.; so a difference of 14° 33′ of longitude on the parallel of 41°, or, by a rough estimate, a distance of 750 miles. Is it possible that ashes ever fell at that distance in such quantities as to terrify the people, and drive them to institute Rogations? Is it likely that a professional historiographer, a resident in the very town where the alarm is said to have occurred, and where the Rogations had been instituted and constantly observed, could have first heard of these facts in Italy and from Italians? If this is scarcely credible, it suggests that we should read Beneventum. It is about thirty miles from the mountain—a distance not so great but that such events might have occurred there. He who wishes to have a vivid picture of them, let him read Pliny's second letter to Tacitus (vi. 20) describing what happened to himself at Misenum. The erroneous reading is somewhat countenanced by the fact that the statement seems intended to be an instance of great distance; whereas probably the heavy fall of ash and the consequent Rogations alone caused Beneventum to be mentioned, and Tripolis was the only case of distance.

While, therefore, the geologists are searching for ash at Vienne, the archæologists might oblige us by searching the annals of the principal Sees round Vesuvius, especially Beneventum. There were also Neapolis, Surrentum, Salernum, and perhaps other Sees, which our bishop might have held, but the scattered rays of light seem best to converge on Beneventum. At a much later date it is described as an Imperial vicariat; did it bear any such relation to the empire in the middle of the fifth century? Did it possess walls, a spacious forum, and a resident nobility? Could people have seen, or have fancied they saw, deer taking refuge in the forum? Is there any record

* It has occurred to me to suggest πρὸς Βάριον ὅρμον for πρὸς Βορρᾶν ἄνεμον This would not be an unnatural reference in the secretary of a Byzantine general, if the Greek emperors already used that port for military purposes.

* My translation of this passage is open to criticism. I have even ventured to read ἀπισχυρισάμενον for ἀπισχυρισάμενοι, and I give an unusual sense to the word, by analogy to ἀποπλουτέω, ἀπομανθάνω, ἀποκραιπαλίζομαι &c. The context seems to me imperatively to demand it. The Latin translation renders the text, as it stands, thus:—"According to them it is now a hundred years or more since the prior roaring occurred; the memory of the other is much more recent; moreover they affirm that it cannot but be, that, &c." Can θᾶσσον be translated by "more recent"? and why such violent asseveration about a simple agricultural fact? The difference does not affect our question; but it is of some importance in its bearing on the History of Vesuvius.

or mention of a Bishop Mamertus, or of some intrusive bishop who may have been Mamertus? Labbe's "Sacrosancta Concilia" (at the British Museum or the London Library) might be consulted to see whether any hint is given of Mamertus having been in Italy, either in the letters of Leo, or (more probably) in those of his successor, Hilary (iv. pp. 1032—1047).

Procopius got his information during the first Gothic war (A.D. 535—540); the second lasted from A.D. 544 to A.D. 548. He died about A.D. 565, at the age of 60. Ought the "century or more ago" to be computed from the date of his information, or from the time when he wrote? This might make a difference of 10 or 20 years. If the former, then the commencement (?) and violence of the eruptions are thrown back to the early part of the fifth century. In any case they must have preceded rather than followed the interval from 455 to 463. Where did Prof. Daubeny get his date of A.D. 472? Certainly not here.

It is therefore very likely that about A.D. 455 Vesuvius may have been in a state of violent activity. In that year Rome was sacked. These are precisely the conditions which the hypothesis requires. Procopius was told that the Rogations were occasioned by such eruptions at about that date. If, then, Mamertus was the sole (?) author of them, he must have been present where the Terrors occurred. Is there positive evidence of the fact? If no positive evidence, for or against, can be found, it will then be time enough to go into other questions of probability. Here for the present I conclude.

HENRY NORTON

WATER ANALYSIS

II.

IN the last article* we assumed that the object of estimating the organic carbon and nitrogen has been fully understood by the reader; but in order to render all chance of our meaning being misunderstood in the remarks which are to follow, it will be as well to briefly capitulate the reasons which render these determinations so valuable. Carbon and nitrogen form with hydrogen the principal constituents of all organised bodies, and hence are found in all the excreta of animals. Nitrogen is found in animals to a much greater extent than in plants, while in the inorganic world this latter element is scarcely found at all, and carbon only in the form of carbon, coal or carbonic acid, none of which bodies are likely to be found in water except the last, the first two being insoluble. It hence follows that if a large quantity, or indeed any quantity, of carbon and nitrogen be found in water, their source can only have been organic in its nature, and if the proportion of nitrogen to carbon be more than one to five, the source is almost absolutely certain to have been animal.

Accordingly, when we find these two elements existing in waters in the proportions just indicated, we are justified in assuming the presence of some form of animal or organic contamination in them; and of all forms in which this contamination can exist, sewage is the most probable. It will thus be seen that when chemists assert that a water is contaminated with sewage, they do so on grounds the truth of which is easily demonstrable. That such waters containing effete animal matters are injurious, no arguments of ours will be required to prove; no persons of authority in sanitary matters have presumed to assert that such waters are harmless.

With regard to the method of obtaining evidence as to this contamination, however, considerable difference of opinion exists, and in the former paper we have endeavoured to show the worthlessness of the early processes of estimating organic matter by ignition of the residue, and by treatment with permanganate of potash; and though this last process is condemned by all, it is still in use.

We have also given reasons for regarding with distrust the results obtained by the use of Chapman, Wanklyn, and Smith's method of indirect determination of organic matter from the amount of ammonia evolved by the water, as we maintain that it cannot be shown that the ammonia evolved bears any distinct relation to the amount of organic matter present, and that with many waters it is difficult to obtain an accurate estimate of the ammonia thus evolved.

The process we have now to consider bases its claims to confidence on the fact that it gives an absolute determination of the quantity of carbon and nitrogen present in the water, and that it does do this can, we think, be proved without much difficulty.

The process is based upon the fact that when a body containing carbon and nitrogen is heated in contact with cupric oxide to bright redness, the carbon is converted into carbonic anhydride at the expense of a portion of the oxygen of the cupric oxide, while the nitrogen is liberated, partly in the free state and partly in the forms of its lower oxides, the quantity of these latter being reduced as much as possible by causing them to pass over the surface of red-hot metallic copper, which abstracts the oxygen and leaves the nitrogen free. In other words, the substances are obtained and estimated by what is known to chemists as a "combustion."

As far back as 1864 an unsuccessful attempt had been made by Weltzien to apply this process to the estimation of carbon in water. The failure was due to the very minute quantities available for estimation, and to the fact that the water was rendered acid with sulphuric acid before evaporation, a proceeding which directly tended to vitiate the results, even had no other obstacle intervened, as the acid gradually concentrated during evaporation, ultimately became sufficiently strong to char and decompose much of the organic matter present.

It was not until Dr. Hermann Sprengel had placed in the hands of chemists a new and powerful means of research in the shape of the admirable air-pump which bears his name, that it was possible to estimate directly the minute amounts of carbon and nitrogen which water, as a rule, contains.

In March 1868 Messrs. Frankland and Armstrong published a method of water analysis which they had elaborated, after eighteen months' work at the subject.

A quantity of water proportionate to the amount of ammonia found,* and varying from one litre in the case of a town water-supply, to 100 cubic centimetres in the case of a much polluted water, is introduced into a flask, and 15 cubic centimetres of a saturated solution of sulphurous anhydride are added, and the water boiled briskly for three minutes; the water is then removed from the source of heat, and a portion introduced into a hemispherical lipless glass dish of about 100 to 120 cubic centimetres capacity; this is placed on a steam bath, and to the first dishful two or three drops of a moderately strong solution of ferric chloride are added. Should the water leave but a small solid residue, or contain little calcic carbonate, a few drops of a solution of sodic sulphite should also be added. The dish is then covered with a cap of filtering paper stretched over a ring of cane, and the evaporation continued, the rest of the water being kept warm in the flask, and added from time to time to the dish. The laboratory in which this operation is performed should be kept free from dust, and no ammonia should ever be allowed in it.

The rationale of the process so far is very simple, and is as follows:—The first boiling with sulphurous acid expels the free carbonic acid in the water, and also any that

* See NATURE, vol. vi. p. 104.

* If the ammonia be less than 0·1 part per 100,000, 1 litre should be used; if more than 1·0, a hundred cubic centimetres or less. (See Sutton's "Volumetric Analysis." J. A Churchill, New Burlington Street, 2nd Edition, 1871, pp 246-295.)

may exist in combination as calcic carbonate, and during the evaporation the remaining sulphurous acid reduces and expels the nitrous and nitric acids present, in which the ferric chloride greatly helps it; the sulphuric acid which is thus formed is neutralised by the calcic sulphite (formed during the preliminary expulsion of carbonic acid) with liberation of fresh sulphurous acid, or should no calcic salt be present, the sodic sulphite is added to effect this.

As soon as the whole of the water is evaporated, the residue is carefully detached from the dish by means of a flexible steel spatula, and thoroughly mixed with some fine cupric oxide; it is then introduced into a stout piece of combustion tube about 430 millimetres long, one end of which has been closed, after having been very carefully cleansed, and which has about 30 millimetres of its length filled up with coarsely granulated cupric oxide.* After the mixed residue and cupric oxide have been introduced, the tube is filled up to within 100 millimetres of the open end with granular cupric oxide; a tightly-rolled cylinder of copper gauze covered with sheet copper, and which has been recently ignited and cooled in a current of hydrogen, is then put in, lastly a few millimetres more of granular cupric oxide, and the tube is then drawn out in the blowpipe flame, put into a combustion furnace, connected with a sprengel pump, and, while the anterior part of the tube is being heated to redness, thoroughly exhausted of air. The pump is then stopped, and the heat gradually carried backwards until the whole of the combustion tube has been heated to redness. Any gas which may come off is collected from the bottom of the Sprengel pump over mercury, and as soon as the gas ceases to be evolved, the furnace is allowed to cool slightly, and the tube again exhausted. The gas pumped off is transferred to an apparatus for the analysis of gases, and measured, after the absence of sulphurous anhydride has been insured by the introduction into the gas of a drop of a solution of dipotassic dichromate. The carbonic anhydride is then absorbed by potassic hydrate, and the gas again measured, the difference being the carbonic anhydride. To the residual gas a minute bubble of oxygen is added to decompose the nitric oxide, should any be present, and after the excess of oxygen has been absorbed by pyrogallic acid, the gas again measured consists of nitrogen; to this half the difference between the two last readings is added, as this represents the nitrogen which had existed as nitric oxide, and the result is the total nitrogen.

All the above data are reduced to measures of weight by the use of the formula. Log. $\frac{\cdot 0012562}{(1 + \cdot 00367\,t)\,760}$ which gives the weight of cubic centimetres of nitrogen in grams. This table of logarithms is carried out for each tenth of a degree from 0° to 30°C.

To those uninitiated in gas analysis, the above may sound very complicated; but in practice it is found extremely simple. The whole analysis, including the calculations, can easily be carried out in half an hour, and the combustion itself need not occupy more, as a rule, than forty-five minutes.

The value of the above process is at once perceived when it is remembered that by it 0·0000005 gram. carbon and 0·0[illegible]001 gram. nitrogen are distinctly measurable quantities. The methods of analysis involving the use of gasometric measurements are by very far the most accurate in the whole range of a science whose very foundations rest on the possibility of accurately weighing and measuring varying quantities. The great capabilities of this method of inquiry have received a splendid demonstration in the researches of Sir Benjamin Brodie on Ozone; and Profs. Williamson and Russell, recognising the peculiar excellence of these methods, have endeavoured with considerable success to make them applicable to a more extended range of work, in connection with which it will only be necessary to remind the reader of the careful determinations of the atomic weights of cobalt and nickel made by the latter chemist.

Notwithstanding these advantages, the application of this method to the determination of the organic constituents of water has encountered the most strenuous opposition in many quarters.

But until a more absolutely certain method of determining the quantities of carbon and nitrogen shall have proved Frankland and Armstrong's process to be in error, it would, indeed, be the height of folly to adopt in its place a method which, like the Albumenoid process, only professes to give a fraction of the nitrogen present (and has absolutely failed to prove that it even gives any known fraction whatever); while it does not even attempt to estimate the carbon at all. Again, over 60 per cent. of the errors given by Frankland and Armstrong in their paper are minus errors, and thus directly tend to favour the Albumenoid process when analysis of waters by the two methods are compared; for the Albumenoid process almost invariably gives less quantities of ammonia than Frankland and Armstrong's does of nitrogen. It must be borne in mind that these absolute errors are almost certainly due to errors in weighing the small quantities of substances used to test the process, quantities so small that they are admitted by the objectors to be only about one-tenth of those usually used in organic analysis.

But in the case of water no weighing at all occurs. A measured quantity of water is taken, and the quantity of carbon and nitrogen which happen to exist in that measure is ascertained, whether it be small or great.

Again, it has been urged that ammonia is lost during the evaporation. This was found to be the case; but it was a difficulty only requiring to be known in order to be remedied. Accordingly, solution of salts of ammonia made acid with sulphurous acid in one case, and with metaphosphoric acid in the other (the last acid replaces the first when sewage is operated on), were evaporated and the nitrogen determined, and from the loss found two tables* constructed, in which each alternate term was an absolute determination, and the intermediate ones calculations. The wonderful constancy with which the numbers alter for each strength of solution shows how accurate the determinations must have been in order to obtain them.

Another valuable proof of the trustworthiness of a process is to be found in the degree of agreement existing between duplicate determinations made with it; and when the process is examined in this way it certainly passes the test in the most satisfactory manner, and the following examples will show how well duplicate determinations agree with each other:—

		Parts per 100,000. Organic Carbon	Organic Nitrogen.
Grand Junction Water Company . .	1	·185	·030

*THE BLIND FISHES OF THE MAMMOTH CAVE AND THEIR ALLIES**

THE blind fish of the Mammoth Cave has from its discovery been regarded with curiosity by all who have heard of its existence, while anatomists and physiologists have considered it as one of those singular animals whose special anatomy must be studied in order to understand correctly facts that have been demonstrated from other sources; and, in these days of the Darwinian and development theories, the little blind fish is called forth to give its testimony, pro or con.

Before touching upon this point, however, we must call attention to the structure of the fish and its allies, and to others that are either partially or totally blind.

In the lancelet (*Branchiostoma*) and the hag (*Myxine*) the eye is described "as simple in form as that of a leech, consisting simply of a skin follicle coated by a dark pigment, which receives the end of a nerve from the brain." Such an eye speck as this structure gives would only answer for the simple perception of light. In the young† of the lampreys (*Petromyzon*) the eye is very small and placed in a fold of the skin of the head, and probably of little use, as these young remain buried in the sand; but as they attain maturity, and, with it, the parasitic habits of the adult, their eyes are developed to a fair size, thus reversing the general rule in the class.

In most other fishes the eyes are developed to a full and even remarkable extent as to size and perfection of sight in water. In *Anableps*, or the so-called four-eyed fish of the fresh waters of Central and South America, which belongs to a closely allied family with our blind fish, the *Cyprinodontidæ*, the eyes are not only fully developed, but are divided into an upper and lower portion in such a way, by an opaque horizontal line, as to give the effect of two pupils, by which the fish probably sees as well when following its prey on the surface with its eyes out of water, as when under water. But it is in the interesting family of Cat fishes (*Siluridæ*) that we find the most singular arrangement of eyes in perfect adaptation to the diversified modes of life of the numerous species. In this family the eyes assume nearly every possible modification from partial and even total blindness to perfectly developed eyes, and these organs are placed in almost every conceivable position in a fish's head; from the ordinary large eyes on the side, to small ones on top of the head, enabling the fish to see only what is above; to the oval eyes on the side, in some just back of the mouth, situated in such a way that the fish can only see what is in close proximity to its jaws or even below them. Many genera of this family found in South America,‡ Africa,§ and Asia,|| have the eyes so small and buried under the skin, or protected by folds or cartilage, as evidently to be of no more use than simply to distinguish light from darkness.

Among the most interesting forms of this family, in this respect, is the genus described by Prof. Cope under the name of *Gronias nigrilabris*. This fish is very closely allied to our common bull pout or horned pout, and of about the same size (ten inches in length). It was taken in the Conestoga river in Lancaster Co., Pennsylvania, where it is "occasionally caught by fishermen and is supposed to issue from a subterranean stream said to traverse the limestone in that part of Lancaster Co., and discharge into the Conestoga." We quote the following from Prof. Cope's remarks on the fish:*—

"Two specimens of this fish present an interesting condition of the rudimental eyes. On the left side of both a small perforation exists in the corium, which is closed by the epidermis, representing a rudimental cornea; on the other the corium is complete. Here the eyeball exists as a very small cartilaginous sphere with thick walls, concealed by the muscles and fibrous tissue attached, and filled by a minute nucleus of pigment. On the other the sphere is larger and thinner walled, the thinnest portion adherent to the corneal spot above mentioned; there is a lining of pigment. It is scarcely collapsed in one, in the other so closely as to give a tripodal section. Here we have an interesting transitional condition in one and the same animal, with regard to a peculiarity which has at the same time physiological and systematic significance, and is one of the comparatively few cases where the physiological appropriateness of a generic modification can be demonstrated. It is therefore not subject to the difficulty under which the advocates of natural selection

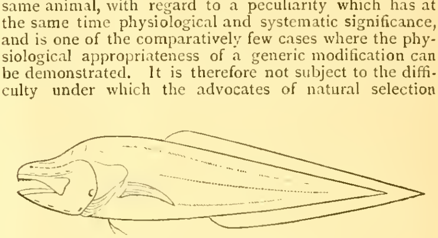

FIG. 1.—Cuban Blind Fish: Lucifuga subterraneus.

labour, when necessitated to explain a structure as being a step in the advance towards, or in the recession from, any *unknown* modification needful to the existence of the species. In the present case observation on the species in a state of nature may furnish interesting results. In no specimen has a trace of anything representing the lens been found."

When we remember that the lens of the eye in *Amblyopsis* has been found, even though the eye is less developed in all its parts than in *Gronias*, it is probable that a careful microscopical examination would show its existence in this genus also.

It is interesting to note that this fish is black above (lighter on the sides and white below), notwithstanding its supposed subterranean habits, and that all the other members of the family having rudimentary or covered eyes are also dark coloured, while the blind fishes of the Mammoth Cave and of the caves in Cuba are nearly colourless. This want of colour in the latter fishes has been considered as due to their subterranean life. If this be the cause, why should the blind cat-fishes retain the colours characteristic of the other members of the family living in open waters?

The fishes which in a general way, so far as blindness, tactile sense, and mode of life are concerned, come the nearest to the blind fishes of the Mammoth Cave, are those described by Prof. Poey† under the names of *Lucifuga subterraneus* and *L. dentatus*.‡ These fishes having

* Reprinted from the *American Naturalist*, a sequel to "The Blind Crustacea of the Mammoth Cave." See NATURE, vol. v. pp. 445, 484.

† These young lampreys have been described under the generic name of Ammocœtes, and it was not until 1856, when Prof. Müller discovered the fact of a metamorphosis in the lampreys, that their true position was ascertained. Prof. Muller has traced the history of the common European species, and shown that it is three or four years in attaining its perfect form. With this fact before us and with the early stages of the Myxinoids still unknown, have we not some reason for suspecting that the lancelet may yet prove to be a larval form of the Myxinoids, notwithstanding that it is said to lay eggs? Why should we not suspect the existence in the very lowest vertebrates of something akin to alternate generations, or of larvæ capable of reproduction? Without having any facts to support such an assumption, except that, on general principles, the young of Myxine would probably be very much like Branchiostoma, and that its young is not known, while Branchiostoma has only been found in waters where some species of Myxinoid exists, I think that before the position of the lancelet is firmly established, we must know the embryology of the Myxinoids; for should the lancelet prove not to be the young of the Myxinoids, it must necessarily form a distinct class of animals, perhaps as near to the molluscs as to the vertebrates.

‡ This species was afterwards referred to the genus *Stygicola* Gill, on account of the presence of palatine teeth which are wanting in the other species. There are also several other good characters, to judge from the figures of the head, skull, and brain given by Poey, that would warrant the reference of the fish to a distinct genus from *L. subterraneus*.

the broad, flattened, fleshy head, with minute cilia, without external eyes, and inhabiting caves so similar in structure to the Mammoth Cave, make a comparison of them with the fishes of the Mammoth Cave most interesting. This is greatly enhanced by the fact that the Cuban fishes belong to a family of essentially marine habit, quite far removed from *Amblyopsis*. The fresh water ling (*Lota*), belonging to the same great group of fishes (though to a distinct family or sub-family) containing the cod on the one hand and the Cuban blind fish on the other, is probably the nearest fresh water relative of the Cuban fish, but the nearest representative yet known is the marine genus *Brotula*, one species of which is found in the Carribean Sea.

In the Cuban blind fish we find ciliary appendages on the head and body quite distinctly developed, evidently of the same character as those of *Amblyopsis*, and answering the purpose of tactile organs. These cilia are in the form of small but plainly visible protuberances (reminding one of the single fleshy protuberance over the opercular opening just back of the head in *Amblyopsis*). There are eight of these on top of the head of a specimen I hastily examined, received from Prof. Poey by the Museum of Comparative Zoology, and quite a number arranged in three rows on each side of the body, showing that tactile sense is well developed in this fish: though it is rather singular that the barbels on the jaws, so usually developed as organs of touch in the cod family and its allies, are entirely wanting in this fish.

The brain of *Lucifuga subterraneus*, as represented by the figures of Poey, differs very much from that of *L. dentatus* and of *Amblyopsis*. In all, the optic lobes are as largely developed as in allied fishes provided with well developed eyes. In *Lucifuga subterraneus* the cerebral lobes are separated by quite a space from the round optic lobes, which are represented as a little larger than the cerebral lobes, and also of greater diameter than the cerebellum; this latter being more developed laterally than in either *L. dentatus* or *Amblyopsis*. The three divisions of the brain are represented, from a top view, as nearly complete circles (without division into right and left lobes), of which that representing the optic lobes is slightly the largest. In *L. dentatus* the procencephalon and the optic lobes are represented as divided into right and left lobes, as in *Amblyopsis*, and the cerebellum does not extend laterally over the medulla oblongata as in *L. subterraneus*, but, as in *Amblyopsis*, is not so broad as the medulla, and, projecting forwards, covers a much larger portion of the optic lobes than is the case in *L. subterraneus*.

The Cuban blind fish has the body, cheeks, and opercular bones covered with scales. As in *Amblyopsis*, the eyes exist, but are so imbedded in the flesh of the head as to be of no use. The outline cut here given (Fig. 1), copied from Poey, is very characteristic of the form of the fish, but does not exhibit the fleshy cilia or details of scaling.

The first notice that I can find of the Mammoth Cave blind fish is that contained in the "Proceedings of the Academy of Natural Sciences of Philadelphia," vol. i. p. 175, where is recorded the presentation of a specimen to the Academy by W. T. Craige, M.D., at the meeting held on May 24, 1842, in the following words:—

"A white, eyeless crayfish (*Astacus Bartoni?*) and a small white fish, also eyeless (presumed to belong to a sub-genus of *Silurus*), both taken from a small stream called the River Styx in the Mammoth Cave, Kentucky, about two and one-half miles from the entrance."

Dr. DeKay, in his "Natural History of New York Fishes," p. 187, published in 1842, describes the fish, from a poor specimen in the Cabinet of the Lyceum of Natural History of New York, under the name of *Amblyopsis** *spelæus*.† De Kay's description is on the whole so characteristic of the fish as to leave no doubt as to the species he had before him, though the statement that it has eight rays supporting the branchiostegal membrane (instead of six), and that the eyes are "large" but under the skin, must have been due the bad condition of his specimen, and to his taking the fatty layer covering the minute eyes for the eyes themselves, as pointed out by Prof. Wyman. Dr. DeKay places the genus with the Siluridæ (cat-fishes), but at the same time questions its connection with the family, and says that it will probably form the type of a new family. In 1843 Prof. Jeffries Wyman* gave an account of the dissection of a specimen in which he could not find a trace of the eye or of the optic nerve, probably owing to the condition of the specimen, as he afterwards† found the eye spots, and made out the structure of the eye. When describing the brain, Prof. Wyman calls attention to the fact of the optic lobes being as well developed as in allied fishes with well developed eyes, and asks if this fact does not indicate that the optic lobes are the seat of other functions as well as of that of sight. He also calls attention to the papillæ on the head as tactile organs furnished with nerves from the fifth pair.

* Obtuse vision.
† Of a cave.

Dr. Theo. Tellkampf‡ was the first to point out the existence of the rudimentary eyes from dissections made by himself and Prof. J. Müller, and to state that they can be detected in some specimens as black spots under the skin by means of a powerful lens. Prof. Wyman afterwards detected the eye through the skin in several specimens. Dr. Tellkampf also was the first to call attention to the "folds on the head, as undoubtedly serving as organs of touch, as numerous fine nerves lead from the trigeminal nerve to them and to the head generally."

It is also to Dr. Tellkampf that we are indebted for the first figure of the fish,§ and for figures illustrating the brain and internal organs. The descriptions of the anatomy of the fish by Drs. Tellkampf and Wyman are all that have ever been written on the subject of any importance, with the exception of the description of the eye by Dr. Dalton, whose paper, in the *New York Medical Times*, vol. ii. p. 354, I have not seen. Prof. Poey gives a comparison of portions of the structure with that of the Cuban blind fishes.

Dr. Tellkampf proposed the name of *Heteropygii*‖ for the family of which, at the time, a single species from the Mammoth Cave was the only known representative, and makes a comparison of the characters with those of *Aphredoderus Sayanus*, a fish found only in the fresh waters of the United States, and belonging to the old family of Percoids, but now considered as representing a family by itself, though closely allied to the North American breams (*Pomotis*), and having the anal opening under the throat, as in the blind fish.

Dr. Storer,¶ not knowing of Dr. Tellkampf's paper, proposed the name of *Hypsæidæ*, for the blind fish, and placed it between the minnow and the pickerel families, in the order of Malacopterygian, or soft-rayed fishes. According to the system adopted by Dr. Günther, it stands as closely allied to the minnows, *Cyprinodontidæ* (many of which are viviparous and have the single ovary and general character of the blind fish), and the shiners, *Cyprinidæ*, of the order of Physostomi. Dr. Tellkampf, in discussing the relations of the family, points out its many resemblances to the family of *Clupesoces*, and its differences from the Siluroids, Cyprinodontes, and Clupeoids, with which it has more or less affinity, real or supposed. Prof. Cope in his paper on the Classification

§ The only other figures of the species, that I am aware of, are the simple outlines given in Poey's "Mem. de Cuba," the woodcut in Wood's "Illustrated Natural History," and the cut in Tenney's "Zoology." None of these figures are very satisfactory.
‖ From the advanced position of the terminus of the intestine being so different from the position which it has in ordinary fishes
¶ "Synopsis of the Fishes of North America," published in 1846.

of Fishes* places the *Amblyopsis* in the order of Haplomi with the shore minnows, pickerel and mud fish, and in an article on the Wyandotte Cave,† he says that the Cyprinodontes (shore minnows) are its nearest allies. This arrangement by Prof. Cope places the Haplomi between the order containing the herrings and that containing the electric eel of South America, all included with the garpike, dog fish of the fresh waters (*Amia*), cat fishes, suckers, and eels proper, &c. in the division of Physostomi as limited by him.

Prof. Agassiz‡ in 1851 stated that the blind fish was an aberrant form of the Cyprinodontes.

Thus all those authors who have expressed an opinion as to the position which the fish should hold in the natural system, have come to the same conclusions as to the great group, division, or order, into which it should be placed. For all the terms used above, when reduced to any one system, bring *Amblyopsis* into the same general position in the system; its nearest allies being the minnows, pickerels, shiners, and herrings; and unless a careful study of its skeleton should prove to the contrary, we must, from present data, consider the family containing *Amblyopsis* as more nearly allied to the Cyprinodontes, or our common minnows having teeth on the jaws, than to any other family, differing from them principally by the structure of the several parts of the alimentary canal and the forward position of its termination.

I have thus far mentioned only one species of blind fish from the cave, the *Amblyopsis spelæus*. The waters of the cave not only contain another species of blind fish, differing from *Amblyopsis* in several particulars, especially by its smaller size and by its being without ventral fins, which I have identified as the *Typhlichthys subterraneus* of Dr. Girard; but also a fish with well developed eyes, as proved by the account given by Dr. Tellkampf, and by the drawing of a fish found by Prof. Wyman, in 1856, in the stomach of an *Amblyopsis* he was dissecting. It is very much to be regretted that the specimen is not now to be found, and that it was so much acted on by the gastric juice as to destroy all external characters by which it could be identified from the drawing which Prof. Wyman made of it, which is of about natural size. Dr. Tellkampf remarks on the fish with eyes are as follows:—

"Besides the colourless blind fish, there are also others found in the cave, which are black, commonly known by the name of mud fish. I saw a dark-coloured fish in the water, but did not succeed in catching it. The latter are said to have eyes, and are entirely dissimilar to the blind fish."

The name "mud fish," given to this fish with eyes, and the statement that it is of a dark colour, together with the drawing by Prof. Wyman of the fish found in the stomach of the blind fish, showing the position of the dorsal fin to be the same as in the fish commonly called mud fish in the fresh waters of the Middle, Western, and Southern States, perhaps indicates the fish with eyes to be a species of *Melanura*. This fish is called mud fish from the habit of burying itself in the mud, tail first, to the depth of two to four inches, and of remaining buried in the mud in our western ditches during a time of drought. This habit, perhaps, in a measure fits it for a subterranean life. The occurrence of a fish belonging to the same family with the blind fish, but with well developed eyes, in the subterranean streams in Alabama, however, renders it probable that the cave fish with eyes may be the same or an allied species, and the drawing by Prof. Wyman would answer equally as well for it.

The fact that the *Amblyopsis* succeeded in catching a fish of probably very rapid and darting movements, shows that the tactile sense is well developed, and that the blind fish must be very active in the pursuit of its prey; probably guided by the movement which the latter makes in the water so sensibly influencing the delicate tactile organs of the blind fish that it is enabled to follow rapidly; while the pursued, not having the sense of touch so fully developed, is constantly encountering obstacles in the darkness.

In describing the habits of the blind fish, Dr. Tellkampf says:—

"It is found solitary, and is very difficult to be caught, since it requires the greatest caution to bring the net beneath them without driving them away. At the slightest motion of the water they dart off a short distance and usually stop. Then is the time to follow them rapidly with a net and lift them out of the water. They are mostly found near stones or rocks which lie upon the bottom, but seldom near the surface of the water."

Prof. Cope, in describing the habits of the blind fish which he obtained in a stream that passes into the Wyandotte Cave, though he entered it by means of a well in the vicinity of the cave, says that—

"If these *Amblyopses* be not alarmed they come to the surface to feed, and swim in full sight like white aquatic ghosts. They are then easily taken by the hand or net, if perfect silence be preserved, for they are unconscious of the presence of an enemy except through the sense of hearing. This sense is, however, evidently very acute, for at any noise they turn suddenly downward, and hide beneath stones, &c., at the bottom. They must take much of their food near the surface, as the life of the depths is apparently very sparse. This habit is rendered easy by the structure of the fish, for the mouth is directed upwards, and the head is very flat above, thus allowing the mouth to be at the surface."

The blind fish has a single ovary, in common with several genera of viviparous Cyprinodontes. In three female specimens of *Amblyopsis* which I have opened, the ovary was distended with large eggs, but no signs of the embryo could be traced. In these three specimens it was the right ovary that was developed, and this was by the side of the stomach, and did not extend beyond it. The number of eggs contained in the ovary was not far from one hundred in the specimen examined. As the embryos develop, the mass probably pushes further back in the cavity and also extends the abdominal walls. That this fish is viviparous is proved by the statement made by Mr. Thompson before the Belfast Natural History Society* that one of the blind fishes from the cave, four and a half inches long, "was put in water as soon as captured, where it gave birth to nearly twenty young, which swam about for some time, but soon died. These, with the exception of one or two, were carefully preserved, and fifteen of them are now before us (at the meeting, I wish they were here), they were each four lines in length."

It is singular that no mention is made regarding these young, as to the presence or absence of eyes, and, as if it was fated that this important point should remain unnoticed as long as possible, it is equally singular that Dr. Steindachner omitted to examine some very young specimens which he received from a friend a few months since and sent to the Vienna Museum, where they will remain unexamined until he returns there. I saw the Doctor only a week after these, to me, interesting specimens had been sent abroad, and he was as grieved as I was disappointed at my being just too late to take advantage of them.

At what time the young are born has never been stated, but judging from such data as I can at present command, I think that it must be during the months of September

* *American Naturalist*, vol. v. p. 579, 1871.

and October. Specimens collected during those months would probably contain embryos in various stages of development, the examination of which would undoubtedly lead to most interesting results.

The largest specimens I have seen of *Amblyopsis* are several males and females, each from four to four and a half inches in length, which seems to be about as large as the fish grows, though Dr. Günther mentions a specimen in the British Museum of five inches in length. The largest specimen captured of late years is said to have been taken during the summer of 1871, and sold for ten dollars to a person who was so desirous of securing the precious morsel that he had it cooked for his supper. The smallest specimen I have seen was one and nine-tenths inches in length.

F. W. PUTNAM

NOTES

ADDRESSES of sympathy with Dr. Hooker, in the difficult position in which he is placed with regard to the management of Kew Gardens, are flowing in on all sides, from those interested in the maintenance of Kew as a scientific establishment. At a meeting of the leading botanists and horticulturists held last week at the office of the *Gardener's Chronicle*, resolutions were unanimously passed expressing the sympathy of the meeting with Dr. Hooker, and in favour of an address to Mr. Gladstone, calling attention to the eminent services rendered by him to science, and pointing out that it is absolutely essential for the efficient management of the establishment at Kew that the Director must have complete control over the subordinate officials, free from any interference in matters of detail from his official superiors. The same course has been followed by the Council of the Royal Horticultural Society, and by its various committees. At a Council of the Royal Botanic Society, specially summoned for the purpose on Saturday last, similar resolutions were passed. The Council of the Meteorological Society has sent to Mr. Gladstone, Lord Derby, Sir John Lubbock, and Dr. Hooker, copies of a resolution in the same direction.

AN interesting *soirée* was held at the Royal Albert Hall on Thursday evening last, under the auspices of the Society of Telegraph Engineers, with the aid of the Postal Telegraph Department. A model of every kind of telegraph instrument which has been generally used for commercial purposes from the opening of telegraphs to the present time was exhibited. Each apparatus was connected up with wires proceeding from the central hall to the galleries, and thus the actual practical working of the telegraph system was made apparent to those present in a very effective manner. A descriptive lecture was at the same time given by Mr. W. H. Preece, of the Postal Telegraph Department, who lucidly explained the action of the electric current in producing the simple elementary signals. The admirable manner in which the lecturer made himself heard in every part of the vast assembly was a general subject of remark. The most interesting feature of the entertainment was the direct and instantaneous working with India. Kurrachee, the terminus of the Indo-European line in India, a distance of upwards of 5,000 miles, was the town selected, and, in reply to a message of inquiry, that station said, "Here, Kurrachee," and followed it up with the announcement that "locusts are swarming in Scinde." After the conversations held with India from the Albert Hall were concluded, the Grand Vizier of Persia, who was at Teheran, sent to the Albert Hall a warm message of congratulation to the Prince of Wales.

Les Mondes speaks with contempt and surprise of the treatment which science meets with at the hands of the British Government, referring particularly to the refusal of the latter to grant a sum for the purpose of enabling scientific men to make marine explorations on the coasts of Europe and India, and to the conduct of Mr. Ayrton towards Dr. Hooker. The latter is spoken of as a gentleman "eminent, talented, universally honoured for his integrity, loved for his courteous manner and the goodness of his heart, and who has devoted to the service of the State a life not only laborious but illustrious."

THE new French Association for the Advancement of Science intends to hold its first meeting at Bordeaux in the month of September next, commencing on the 5th.

WE are sorry to see the following paragraph in *Les Mondes* of July 18:—"No one has yet responded to the appeal we made to the French *savants* to take part in force (*en nombre*) in the Brighton meeting, which opens on August 14. We shall not organise this scientific excursion unless we are able to count upon a sufficient number of adherents. There is no time to lose." We hope it is not too late, and that something like a representative party may be yet organised from among all classes of French men of science. We are sure we can promise they will be heartily welcomed and hospitably treated at Brighton.

THE Annual Meeting of the British Medical Association will be held in Birmingham on the 6th, 7th, 8th, and 9th days of August next.

MR. W. A. TILDEN, D.Sc. Lond., Demonstrator of Practical Chemistry to the Pharmaceutical Society, has been appointed Chemical Master in Clifton College.

BY the provisions of the late Dr. William J. Walker's foundation, two prizes are annually offered by the Boston Society of Natural History for the best memoirs, written in the English language, on subjects proposed by a Committee appointed by the Council. For the best memoir presented, a prize of sixty dollars may be awarded; if, however, the memoir be one of marked merit, the amount may be increased, at the discretion of the Committee, to one hundred dollars. For the memoir next in value a sum not exceeding fifty dollars may be given; but neither of these prizes is to be awarded unless the papers under consideration are deemed of adequate merits. Memoirs offered in competition for these prizes must be forwarded on or before April 1, 1873, prepaid, and addressed, "Boston Society of Natural History, for the Committee on the Walker Prizes, Boston, Mass." Each memoir must be accompanied by a sealed envelope enclosing the author's name, and subscribed by a motto corresponding to one borne by the manuscript. The subject of the Annual Prize of 1873 will be "On the Development and Transformations of the Common House Fly."

THE Academy of Sciences and Belles Lettres of Caen has offered a prize of 4,000 francs for a paper on "The part played by leaves in vegetation." What is wanted is an account of exact experiments and new facts calculated to clear up, invalidate, confirm, or modify the doubtful points in the received theories. Papers must be sent in before December 31, 1875, addressed to M. Travers, secretary of the Academy, Caen.

ON Thursday last Mr. Thomas Baring, M.P., F.R.S., distributed prizes and certificates to the students who had passed the examinations connected with the educational courses of lectures delivered at the London Institution during the past session. In the examination on Prof. Huxley's lectures, "On the Physiology of Bodily Motion and Consciousness," the first prize was gained by H. B. Hyde, jun.; the second by Miss Caroline Lloyd; and the third by A. J. Wallis. In the examination on Dr. Odling's course, "On Elementary Chemistry," the first, second, and third prizes were carried off by H. Louis, A. J. Richardson, and Miss Eleanor F. Garrett. In the examination connected with the lectures "On the Theory of Music," delivered by Mr. E. J. Hopkins, the first prize was obtained by Alfred Hare, and the second by Miss Frances S. Voysey. In

the examination on Prof. Bentley's course, "On the Classification of Plants," Miss Eleanor F. Garrett gained the first prize, Miss Elizabeth J. Garrett the second, and L. T. Thorne the third. Sixty-six Pass Certificates were granted, and no fewer than twenty-two young ladies were among the successful candidates.

WE are glad to see from the report on the teaching of Practical Physiology in the London schools, which appears in the *Medical Times* of Saturday, that the means and method for teaching this subject to University College, the only one yet reported on, are in every way satisfactory.

Harper's Weekly records the death of Mr. Coleman T. Robinson, of New York, a gentleman well known for the attention he has paid to the subject of American lepidoptera. A man of wealth, and able to gratify his tastes in this direction, he acquired, by his own efforts and by purchase, a very extensive cabinet, embracing over twenty thousand specimens, which not long ago he presented to the American Museum of Natural History in the Central Park. Mr. Robinson published quite extensively upon American lepidoptera—a paper upon the sphinges of Cuba being perhaps the most important. In some of his labours he was associated with Mr. Grote.

WE hear from America of the death of Mr. Robert Swift, who had paid great attention to terrestrial and marine mollusca. His valuable cabinet of shells will be presented by his daughter to the Philadelphia Academy of Sciences. He had already given to the Museum of the Smithsonian Institution an extensive series of specimens of the birds of St. Thomas and Porto Rico.

A MONUMENT has been erected to Boerhaave, the great naturalist and physician, at Leyden in Holland. The statue is 11 ft. 8 in. high, and stands on a pedestal of 10 ft. in height. The figure represents him as a professor lecturing.

WE learn from the *Times of India* of June 28 that the *Madras Mail* and other journals in the Madras Presidency are altogether discontented with the recent judgment of the Court of Inquiry as to the cyclone, to which we referred last week. The *Mail* has subjected the judgment to a searching criticism, and, after comparing it with the evidence, concludes that the Court throughout has erred egregiously on the side of severity. It seems to be thought that the Board of Trade will either reverse or modify the Court's judgment.

DR. E. DECAISNE, in a note communicated to the Academy of Sciences on the 3rd of June, shows that from the triple point of view of the fecundity of marriages, of the absolute number of births, and of the excess of births over deaths, France occupies the lowest place of all the European States. In Prussia 100 marriages give 460 children; in France the same number of marriages give only 300 children. In Prussia the number of births for each 100 of the population generally is 3·98 per annum; in France there are only 2·55. In Prussia the excess of births over deaths in each million of the population is 13,000 per annum, whilst in France it only amounts to 2,400. "If we admit," says Dr. Decaisne, "as a conclusion from the above figures, that the doubling of the population of France, despoiled of two of its finest provinces, and by unheard of disasters, will require 170 years to be effected, whilst that of Prussia requires only 42 years, Great Britain 52, and Russia 66, some estimate may be made of the amount of the evil that has befallen this country." He does not hesitate to say that, as the first step towards the restoration of the former power of France, the first thing that should occupy her statesmen is the reconstitution, the reorganisation of human life; and everyone should throw aside that false patriotism which has been the cause of so much ill.

AT its last session the Congress of the United States made an appropriation of 75,000 dollars for the continuation of Professor Hayden's geological exploration of the Territories; and on the 15th of June the Professor had already established his camp at Ogden, Utah, preparatory to prosecuting his researches. The present session seems likely to be marked by still further additions to our knowledge of the physical and natural history of the central and western regions of the United States.

ACCORDING to the *Yale College Courant*, a new era in the educational development of the Japanese has been entered upon in the opening of an exhibition of curiosities of nature and art in Yedo in the beginning of April last. The formation of collections of this kind is usually characteristic of an advanced stage of culture; and in imitating the European and American example in this respect the Japanese show their great superiority to the Chinese and other Oriental nations. The exhibition referred to was opened in a temple sacred to the spirit of Confucius, and situated in the grounds of the old Chinese college. This institution was the chief seat in Japan of the study of Chinese literature, but has been closed for some years, as the study of the Chinese has now become obsolete. The exhibition, to which a charge for admission of about two cents was made, was projected by the Japanese themselves; and although small, yet, according to the writer in the *Courant*, it was really very good and well selected. The specimens were those mainly pertaining to the fauna and flora of Japan, embracing reptiles, fishes, insects, and birds, the last being well stuffed and mounted. Specimens of timber, in polished slabs, were exhibited; and the cases of insects were filled with a very great variety of species. To the wonders of nature were added numerous art curiosities, mainly of old and rare patterns of articles of lacquered bronze.

A CORRESPONDENT of the *Chemical News* asks why the Cavendish Society has for years ceased to publish works of scientific value, and suggests that some of the works of its founders and officers—Faraday, Graham, Hofmann, Daubeny, Miller, Stenhouse—as well as others, are so scarce, that their publication by the Society would be a boon to many, and would remunerate it for its trouble in publishing them.

GENERAL MYER, the indefatigable head of the United States Signal Service, has proposed, according to *Harper's Weekly*, to take the occasion of various balloon ascensions during the present season, especially from Boston, to make observations in regard to the temperature, barometric pressure, and the currents of the higher altitudes of the atmosphere. Sergeant Schaeffer, of the corps, has been detailed for this purpose, and has been in training for some time preparatory to his important work.

WE learn from the Fifth Annual Report of the Peabody Institute of Baltimore, for the year ending June 1, that upwards of 13,000 dollars have been spent on books and binding, and that during the year 120 lectures have been delivered at the Institute —30 being popular lectures, and 90 what are called class lectures, designed for more minute instruction in special branches of knowledge." Of the popular lectures Prof. W. H. Miles gave ten—mostly geological—on such subjects as "Revelations of the Microscope and of the Deep-Sea Soundings," "Coral and the Coral Islands," "Glaciers, Rivers, and Oceans," "The Geological History of Man," &c. The class lectures are divided into six courses, of which two are scientific—the one consisting of twenty lectures on Physiology by Prof. F. T. Miles, of Maryland University, and the other twenty lectures on Sound and Heat by Prof. H. C. White, of St. John's College, Baltimore. The average number in each class, independent of single admission, was thirty-seven, the charge for a course of twenty lectures being only 3 dols. During the year 3,883 volumes besides pamphlets have been added to the library, the number of readers having been 2,582.

JUDGING from the Report of the Exeter Science School in connection with the Government Department of Science and Art, it seems altogether in a very satisfactory condition. There are classes for Physical Geography, Mathematics, Acoustics, Light and Heat, Chemistry, Animal and Vegetable Physiology, Geology, Mineralogy, Metallurgy, Botany, Building Construction, Theoretical Mechanics, Machine Construction, and Drawing. From the number who have passed the examinations, it would appear that the classes must have been well attended, and several of the students have most creditably distinguished themselves.

THE following is a list of the electric lights in England and France with the dates at which they were erected :—Dungeness, Jan. 1862 ; Cape La Heve, France, South Light, Dec. 1863 ; North Light, Nov. 1866 ; Cape Grisnez, France, Feb. 1869 ; Souter Point, England, Jan. 1871 ; South Foreland, 2 lights, Jan. 1872. It is interesting to see that England took the lead in this matter of the adaptation of electric illumination to lighthouse purposes, and it must also be remembered that although the first electric light was only erected in 1862, yet that in 1859 experiments were made under the supervision of the late Prof. Faraday which were very successful.

MR. WILLIAM F. DENNING, of Bristol, writes us that the sun's surface has recently been in a very disturbed condition. On observing the sun on the afternoon of the 12th instant with an old 4in. metallic-mirror reflecting telescope, he noticed a large scattered group of spots in the north-eastern quadrant of the disc. This group contained no less than twenty-seven individual spots, one of which was of considerable dimensions. It was situated on the eastern portion of the group, and was constituted of three well-defined umbræ and a large irregular penumbra, which on the east side was very dark, and on the exterior edge pierced with a train of minute dark spots. In the other quadrants Mr. Denning noticed four groups and one isolated spot surrounded by penumbra in the north-western quadrant. These groups (though insignificant in regard to the dimensions of the spots which composed them) contained twenty-one spots in all ; so that, including the large cluster before referred to, there were forty-eight dark spots seen altogether. Several groups of faculæ were also perceptible in the vicinity of the margin of the disc.

THE first number of the *Journal of the Society of Telegraph Engineers* contains, besides a list of members, and the rules and regulations, a record of the proceedings of the Society since its formation, including reports of the papers read, and the discussions which followed. The members already number about 280, and among them are the names of some of the most eminent scientific men of the time, the President being Charles W. Siemens, and the Vice-Presidents Lord Lindsay and Frank I. Scudamore, C.B. The society "Is established for the general advancement of Electrical and Telegraphic Science, and more praticularly for facilitating the exchange of information and ideas among its members," and consists of members, associates, students, and honorary members. Besides the President's address, in which he justly maintains that such a special society "is necessary for the more rapid development of a new and important branch of applied science," the report contains a paper by Mr. R. S. Culley on Automatic Telegraphs, and a sketch of the Progress of Sea Telegraphy by Captain Colomb, R.N. The latter half of the volume consists of "Abstracts and Extracts," bearing on the department with which the society is concerned.

A NOVEL kind of magazine has made its unpretending appearance—*Loose Leaves*, a magazine conducted at the Church Stretton Private Asylum. It is written almost entirely by members of the asylum, and we have seen many madder publications proceeding from those who consider themselves sane. As an effort to occupy the minds of the unfortunate inmates of such establishments, the attempt is commendable, and worthy of all success and imitation.

HISTORICAL ECLIPSES

MR. J. R. HIND, writing from Mr. Bishop's Observatory, Twickenham, to the *Times*, supplies the following interesting sketch of the Eclipses recorded in History :—

"It is well understood that the historical eclipses, especially those of the sun, have an important bearing upon our knowledge of the elements of the moon's motion, as affording the means of testing the accuracy of those elements when carried back to very remote times. I send you a brief account of some results I have deduced in a systematic examination of these eclipses, making only such a selection therefrom as may possibly possess interest for the general reader. I shall omit any reference to the purely astronomical conclusions to which I have been led, which would be out of place in your columns, and, indeed, would extend this communication beyond reasonable limits. It may, however, be desirable to state that I have employed the last value of the secular acceleration of the moon's mean motion given by Prof. Hansen, of Gotha, the author of the latest lunar tables, and have combined other important elements as determined by him with the results of M. Leverrier's tables of the sun. From recent investigations it appears by no means improbable that we may have to rely wholly upon the ancient eclipses in fixing the true amount of acceleration in the motion of our satellite.

"I shall follow the chronological order in the subjoined remarks upon some of the better known eclipses of history. These form a part only of the phenomena I have rigorously examined upon the same system of calculation.

"1. The Nineveh Eclipse of B.C. 763, June 15.—The discovery of the record of this eclipse on one of the Nineveh tablets in the British Museum was announced by Sir Henry Rawlinson in the *Athenæum* of May 18, 1867, to which I refer for details of its bearing on the sacred and profane history of the period. In the actual state of our knowledge it is the *terminus a quo* for researches on the historical eclipses, and I believe I am correct in saying its value in an astronomical point of view is greater than that attaching to the famous eclipse predicted by Thales to the Ionians, as mentioned by Herodotus. The underlining of the inscription appears to indicate a phenomenon of unusual character, or that the eclipse was total in or near Nineveh. Adopting for the position of the city the longitude and latitude deduced by the Astronomer Royal for the pyramid of Nimrud, I find the calculated southern limit of totality would pass a few miles south of Nineveh, leaving a very large partial eclipse at that city. Very trifling corrections in the lunar elements employed would suffice to bring the total eclipse over it. In this longitude the duration of totality on the central line would be 4m. 20s., the middle of the eclipse at half-past 9 local time.

"2. The Eclipse of B.C. 689, January 11.—The idea that the retrogression of the shadow on 'the dial of Ahaz' during the illness of Hezekiah may have been connected with a solar eclipse has given rise to much discussion, and several writers have endeavoured to point out how the occurrence might thus be explained. Of the eclipses to which attention has been directed, the above has perhaps appeared the more probable. It was an annular eclipse, and at Jerusalem the sun would present the form of a luminous ring for 7½ minutes, the middle at 10h. 18m. In Babylon it would have the same appearance for seven minutes. It seems hardly probable that the eclipse could have occurred much later in the day, though more than one author has considered the circumstance essential for the explanation of the retrograde motion of the shadow on the ancient form of sun-dial by an eclipse. I must leave the reader to judge how far the expression 'the wonder done in the land' may relate to such a phenomenon, which is, of course, a very rare one in a particular locality.

"3. The eclipse of Thales, B.C. 585, May 28.—This eclipse, which, as Herodotus informs us, terminated the six years' war between the Medes and Lydians under Cyaxares and Alyattes, when during a battle 'day was suddenly turned into night,' has greatly exercised the chronologist and the astronomer, and although, misled by imperfect tables of the lunar motions, they have fixed upon other eclipses from time to time, it has been known for some years past that the date distinctly assigned by Pliny (the fourth year of the 48th Olympiad) is the correct one. My new calculation throws the shadow precisely over the tract of country where with the greatest probability it has been supposed the contending armies were situated, and in addition it indicates a circumstance which I believe has not resulted from any previous calculation, and which may not be without its

chronological import, viz., that the eclipse was total in Nineveh for between three and four minutes shortly before sunset. The date of the final destruction of Nineveh is closely connected with the eclipse of Thales.

"4. The Eclipse of Xerxes, B.C. 478, February 17.—Much difficulty has been experienced by chronologists with regard to an eclipse which occurred, according to Herodotus, in the early spring, when Xerxes was setting out from Sardis on his expedition against Greece. It is certain there was no such phenomenon in the year B.C. 480, to which this event is usually referred, and in examining the eclipses about this period I have found only one that can apply. There is no doubt that the sun was very largely eclipsed at Sardis on the morning of February 17, B.C. 478. A direct calculation for this place shows that more than 94-100ths of the sun's diameter would be covered, the greatest phase ten minutes after 11, local time. The eclipse was annular, and Sardis appears to have been just outside the annulus. One other eclipse only was visible in eastern Europe about this year, it occurred B.C. 479, October 2, and has been considered to be the one which occurred at the time Cleombrotus consulted the oracles at Sparta. Its magnitude there is found to have been about 6-10ths, the greatest eclipse at 0h. 50m. If the eclipse of B.C. 478 be truly the one recorded by the historian, the date of the battle of Salamis will be required to be brought down two years.

"5. The Eclipse of Agathocles, B.C. 310, August 15 (Diodorus, Justin).—On the morning after the fleet of Agathocles sailed from Syracuse for Africa, the historian tells us the sun was eclipsed to such a degree (*tantum fit solis deliquium*) that the stars everywhere appeared as at night. Though Agathocles could hardly have been more than 100 miles from Syracuse, it is uncertain in which direction he had sailed, or whether he was rounding Sicily on the north or south side, and this circumstance detracts from the scientific value of the record. My calculation throws a central line near the African coast, so that the fleet, if sailing southwards, would be near the northern limit of totality.

"6. The Eclipse on the Passage of the Rubicon by Cæsar (Dion), B.C. 51, March 7.—This would appear to have been a very notable phenomenon on the Rubicon and in Northern Italy generally. The eclipse was annular, and the annular phase continued 6m. 30s. At Rome there would be a partial eclipse, about three-fourths of the sun's diameter being covered. A line drawn from 9° 24′ E., and 43° 26′ N., to 14° 39′ E., and 46° 15′ N., will define the course of the central eclipse across Italy, and the ring-formed appearance of the sun would extend to about 1° 35′ north and south of this line. The Rubicon would be placed about midway between the central line and the southern limit. Near Ariminum the middle of the eclipse occurred at 0h. 50m. By some writers (including the Abbé du Fresnoy, in his valuable 'Tablettes Chronologiques,') the eclipse is dated B.C. 50; the above, however, is the correct year.

"A great eclipse has been referred to the year B.C. 43 or 44, soon after the death of Julius Cæsar, and it is instanced by Baron de Zach and M. Arago as the first annular eclipse upon record. Calculation shows that there could not have been an eclipse, annular or otherwise, visible in Italy in either of those years, nor, indeed, for several years before or after. The phenomenon alluded to was, no doubt, of a meteorological character, and this would appear from the passage in Suetonius, one of the authors quoted upon the subject.

"7. The Eclipse of Herod (Josephus).—The lunar eclipse which I take to be the one recorded by the Jewish historian during Herod's last illness occurred B.C. 1, January 9. On this occasion the moon passed nearly centrally through the earth's shadow, entering in at 11h. 23m. P.M. mean time at Jerusalem, and emerging at 2h. 57m. A.M. on the 10th; the total eclipse continued 1m. 39s. This is the date recognised by Calvisius and recently supported by Mr. Bosanquet. An eclipse in B.C. 4 on the night between March 12-13, which other chronologists have supposed to be the one referred to, was partial only, and did not commence till 1 A.M.; little more than half the moon's diameter was immersed in the earth's shadow at greatest phase.

"8. The Eclipse of Phlegon in the 202nd Olympiad (Eusebius) A.D. 29, November 24.—Total on a line crossing the Black Sea rather west of Odessa in Sinope, thence near the site of Nineveh to the Persian Gulf. At Jerusalem a partial eclipse; about 11.10 A.M. eight-tenths of the sun's diameter would be covered; at Heliopolis (Baalbec) also partial—nine-tenths. At a point on the central line near Sinope the totality would continue $1\frac{1}{2}$ minutes. Humboldt mentions that this eclipse had been calculated by Wurm, but I have not met with his results. It is the only solar eclipse that could have been visible in Jerusalem during the period usually fixed for the ministry of Christ.

"The moon was eclipsed on the generally received date of the Crucifixion, A.D. 33, April 3. I find she had emerged from the earth's dark shadow a quarter of an hour before she rose at Jerusalem (6.36 P.M.): but the penumbra continued upon her disc for an hour afterwards.

"9. The Eclipse of 113, May 31.—Kepler, after endeavouring to ascertain the date of a total eclipse mentioned by Plutarch as having 'recently occurred about noon,' when the darkness was like that of night, and stars were seen in all directions, states he had found none which accorded better with the description than the above. On submitting it to calculation on the modern elements, the central line appears to have passed too far north—over central Germany. I have not succeeded in discovering the date of this eclipse, though I have accurately examined several at the close of the first and beginning of the second century.

"10. The Eclipse of 418, July 19.—Very large at Constantinople, according to Philostorgius, who relates that at the eighth hour of the day the sun was so far eclipsed that the stars appeared, and a comet which had not been previously perceived became visible during the obscurity, and was watched for more than four months afterwards. According to my calculation the central line passed somewhat to the south of Constantinople, where ninety-five hundredths of the sun's diameter would be covered. At a very short distance below that point the eclipse would be total. This is the second occasion upon which the discovery of a comet during a total, or nearly total, eclipse of the sun is recorded in history.

"11. The Eclipse of 671, December 7, on the attempted removal of the pulpit of Mahomet from Medina.—Prof. Ockley, in his 'History of the Saracens,' mentions on the authority of several Arabian writers, a large solar eclipse which occurred about the 52nd year of the Hegira. The Caliph Moawiyah having formed the intention of removing the Prophet's pulpit from Medina to his residence at Damascus, his people proceeded to do so, 'when immediately to their great surprise and astonishment the sun was eclipsed to that degree that the stars appeared.' Baron de Zach refers the eclipse to 674, October 4, but in this he is certainly mistaken—I believe through a wrong assumption as regards the moon's latitude. The correct date would appear to be 671, December 7. The eclipse of this day was annular on the central line. At Medina the greatest phase occurred at 10h. 43m., when 85-100ths of the sun's diameter would be obscured. In the clear skies of that part of the world such a degree of eclipse might be sufficient to bring out the brighter planets or stars. No larger eclipse, visible at Medina, occurred about this epoch.

"12. The Eclipse of 840, May 5.—Among the causes which are said to have brought on the *maladie de langueur* that terminated the life of Louis le Débonnaire was 'the fright which a total eclipse of the sun had occasioned him.' It is related that the King was taken ill at Worms, and having been removed to Ingelheim, near Mayence, he died there on June 20. I find the northern limit of totality in this eclipse passed about 100 miles south of Worms, and on the central line in this longitude the total eclipse continued 5m. 25s., an unusually long interval for the latitude of Central Europe. The middle occurred at 1.15 P.M., with the sun at an altitude of 57°. The phenomenon under such circumstances must have been a very imposing one, and well calculated in those days to inspire alarm.

"I have already described in your columns the track of the total eclipse of 1140, March 20 (William of Malmesbury) across this country, and merely refer to it now to add, that if any one of your readers is aware of its being recorded as total in London, he might be doing an astronomical service by making the fact generally known.

"13. The Eclipse of 1133, August 2 (William of Malmesbury), a great solar eclipse, considered as foreboding evil to Henry I. of England.—The central line traversed Scotland from Ross to Forfar, and the eclipse was, of course, large in every part of the country. It would be total in Northumberland. In the centre of Forfarshire totality continued 4m. 20s. Berwick-upon-Tweed was about 20 miles within the south limit.

"During the existence of the kingdom of Jerusalem there is mention of an eclipse which would appear to have been total in the city or its immediate neighbourhood, and has been variously dated from the election of Godfrey of Bouillon in 1097. I am

inclined to think it must be to the eclipse of August, 1133, that the record applies, though previous or subsequent events may have been mixed up with it by the historian. Continuing the calculation of the track of total eclipse after leaving this island, I find it would enter Palestine near Jaffa, and pass over Jerusalem and Hebron, where the sun would be hidden 4¼ minutes about 3 P.M., and from Nablous on the north to Ascalon on the south the country would be in darkness for nearly the same interval. The magnitude of the eclipse of 1187, September 4, was rather more than 9-10ths at Jerusalem, the central line passing between eight and nine degrees to the north; in the eclipse of 1191, June 23, the magnitude was about 7-10ths.

"14. The Eclipse of 1433, June 7, long remembered in Scotland as "the black hour."—It was a remarkable eclipse, the moon being nearly in perigee and the sun not far from apogee. The central line traversed the country in a south-easterly direction, from Ross to Forfar, passing near Inverness and Dundee. Maclaurin mentions that in his time a manuscript account of this eclipse was preserved in the University of Edinburgh, wherein the darkness is said to have come on about 3 P.M., and to have been very profound. By direction calculation for Edinburgh I find the total eclipse commenced at 3h. 3m., and continued 3m. 41s. At Inverness totality continued 4m. 32s. The after course of this eclipse was north of Frankfort on the Main and Munich, over the Dardanelles, south of Aleppo, and thence nearly parallel to the course of the Euphrates to the north-east border of Arabia. The totality was observed in the Turkish dominions according to Calvisius.

"15. The Eclipse of 1598, February 25.—Maclaurin says the memory of this eclipse was preserved among the people of Scotland, and 'that day they termed Black Saturday.' He adds:—'There is a tradition that some persons in the north lost their way in the time of this eclipse, and perished in the snow'—a statement the probability of which our experience of recent phenomena by no means tends to support. The central eclipse may be described as having passed about five miles south of Stranraer to the Bass Rock, a little south of Edinburgh, or, more precisely, over Dalkeith. Totality came on at Edinburgh at 10h. 15m., and continued 1m. 30s. The duration was the same at Douglas, Isle of Man. From the rapid motion of the moon in declination the course of the central line was a quickly-ascending one, in latitude on the earth's surface, the total eclipse passing off within the Arctic circle. Kepler must refer to another eclipse which was observed by Jessenius at Torgau, on the Elbe, though he gives the above date.

"16. The Eclipse of 1652, April 8, to which reference is also made by Maclaurin as 'still famous among the populace of Scotland, and known among them by the appellation of Mirk Monday.'—The central line passed over the south-east of Ireland, near Wexford and Wicklow, arrived on the shores of Scotland near Burrow Head, Wigtonshire, and running within a few miles from Edinburgh, Montrose, and Aberdeen, left the island at Peterhead. Greenock and Elgin would be situate near the north limit, and the Cheviots and Berwick upon the south limit of totality. The eclipse was observed at Carrickfergus, Ireland, by Dr. Wyberd. I find by direct calculation for this place that it was only just within the north limit of totality, which would commence at 10h. 8m. 30s., and continue 44 seconds. This short duration may partly explain a curious remark of Dr. Wyberd, that when the sun was reduced to 'a very slender crescent of light, the moon all at once threw herself within the margin of the solar disc with such agility that she seemed to revolve like an upper millstone, affording a pleasant spectacle of rotatory motion.' Wyberd's further description clearly applies to the corona.

"I believe it has been generally supposed that the last total eclipse of the sun visible in England was that of 1715, May 3, so well recorded by Halley in the 'Philosophical Transactions' of the Royal Society, and I was under this impression myself until, on calculating the elements of the eclipse of 1724 (May 22), observed at Paris, and by the French King at the Trianon, I discovered that before reaching France the belt of totality must have traversed the south-west of England, and it now appears that the totality did not pass by us unrecorded.

"I am indebted to the Astronomer Royal for referring me to an account by Dr. Stukeley, who observed the eclipse from Salisbury Plain. The duration of totality in that locality would be rather less than three minutes. The eclipse of 1724 is therefore the last that has been total in England, and as I have shown in a previous communication, there will be no other till August 11, 1999, and that will be confined to the south-west corner of the country."

*ON PHOTOGRAPHIC IRRADIATION IN OVER-EXPOSED PLATES**

THE most cursory observer of any of the recent corona photographs must have remarked the apparent eating-in of the prominences over the limb of the dark Moon. A more careful examination of the photographs shows that the whole limb of the Moon is more or less eaten into, and that the indentations under the prominences are only exaggerations of a phenomenon which is present at all parts of the limb, but which varies in intensity according as the dark limb of the Moon is projected on a brighter or less luminous background.

In all over-exposed photographs of luminous objects upon a dark background, the brighter parts of the picture are found to be surrounded by a nebulous haze or border of light, which increases the diameter of the image formed by the luminous objects at the expense of those which are less luminous.

This nebulous haze has often been spoken of as "the extension of the chemical action," but without begging the question of its cause, we propose to speak of it as photographic irradiation. It has been found to vary with the time of exposure, and the relative brightness of the object and its background.

On examining the effects of photographic irradiation in a decidedly over-exposed picture, it will be seen that the nebulous fringes round luminous objects are distinctly divided into two parts—an inner and very marked border of light, following the contour of the luminous objects, and an outer and much less definite haze, thus:—

FIG. A

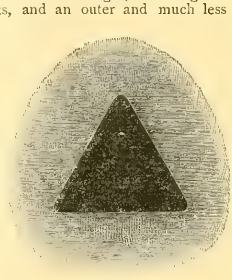

FIG. B

where Fig. A represents a normal photograph, and Fig. B a decidedly over-exposed plate from the same object.

The inner border of light fades gradually from the inside outwards, and it is very difficult, and indeed impossible, to tell where the true image of the luminous object ends, and its photographic irradiation begins. While, on the other hand, the boundary between the outer and inner fringes (or halos) of irradiation is more definitely marked, although it would be difficult to say with any absolute precision, at what point the inner fringe terminates.

Our first experiments were devised in order to test whether reflections from the back surface of the plate played any part in the production of the fringes; for this purpose plates of ebonite and the so-called non-actinic yellow glass were prepared.

In the over-exposed photographs taken on ebonite, it was found that the outer haze had entirely disappeared; while in the photographs taken on plates of yellow glass the outer haze is still distinctly to be traced, though it is much fainter than on an ordinary white glass plate with the same exposure.

By placing a piece of wetted black paper at the back of an unground plate the outer haze may be greatly reduced, while it was found that by grinding both the back and the front surfaces of a yellow glass-plate, and covering the back with a coating of black varnish, the outer haze may be rendered quite imperceptible, while, however, the inner border of irradiation still remains as before.

From these experiments we may conclude that the outer haze is produced by reflections from the back of the plate; and the action of the wetted black paper in reducing the outer irradiation may be explained by the consideration that the change of refractive index in passing from the glass to the film of water behind, is much less than in passing from glass into air. There is, consequently, less reflection at the back surface of the plate; most

* By Lord Lindsay and Mr. A. Cowper Ranyard. Reprinted from the Monthly Notices of the Royal Astronomical Society, June 14, 1872.

of the light emerges into the film of water, and is then absorbed by the black paper.

Fig. C represents a photograph taken upon a yellow glass plate, with a backing of wet black paper, but otherwise exposed under similar conditions to the photograph represented in Fig. B.

FIG. C

The outer irradiation halo may therefore be entirely avoided for the future in any corona or other necessarily over-exposed photographs by the use of the opaque plates. If, however, it is considered important that the negatives should be capable of being copied by transmitted light, the outer halo may still be to a great extent avoided by the use of transparent glass plates with a backing of wet black paper or black varnish.

Secondly, as to the inner and more definitely-marked irradiation edge which remained and seemed to be unaffected by the precautions that had served to rid us of the outer halo. Since the inner fringe was equally to be found on an opaque and on a transparent plate, we felt ourselves justified in seeking for its cause in front of the first or upper surface of the prepared plate; that is, it must be referred either to some action taking place within the thickness of the collodion, or to the optical imperfections of the instrument.

In order to determine whether the scene of action lay within the thickness of the collodion, we placed an ivory ruler with a bevelled edge in immediate contact with the collodion film. The plate with the ruler upon it was then exposed within the camera, so that the image of an incandescent platinum wire fell partly upon the collodion film, and partly upon the ivory ruler. If the scene of action lay within the collodion film, we might expect the inner irradiation fringe to extend itself under the edge of the ruler, while if it were due to the optical imperfections of the lens, the image of the wire would be cut off sharply by the edge of the ruler.

On removing the plate from the camera, and before the ruler was shifted from its place on the collodion, the whole was exposed for a few seconds to the action of the light from a gas-burner, in order that the position occupied by the edge of the ruler might be faintly printed upon the collodion film. On developing the plate, it was found that the image of the wire was sharply cut off at the place occupied by the edge of the ruler, as in Fig. D.

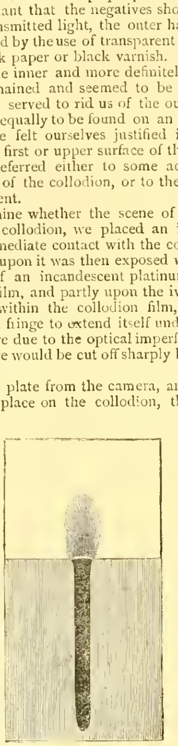

FIG. D

The very faint action extending inwards under the ruler being evidently due to the want of perfect opacity in the ivory, it seems, therefore, to be clearly proved that the inner irradiation edge is not caused by any chemical or other action taking place within the thickness of the collodion; but must be referred to the optical imperfections of the instrument which throws the image upon the collodion film.

It is instructive to remark that the photographic image of the wire is not cut off by an absolutely straight line at the edge of the ruler, but it is slightly convex, and is separated from the faint action which has apparently taken place through the ruler by a very narrow bright line, which appears to indicate the presence of a small capillary film of liquid along the edges of the ruler, forming a minute cylindrical lens. At the point where the collodion was acted upon by the light, the minute cylindrical lens appears to have been interfered with, and depressed inwards towards the ruler; we may therefore conclude that the collodion film is slightly swelled or thickened by the action of the light upon it.*

The cause of the inner irradiation-edge seems to be that every point of a luminous object is not represented by a simple point of light in the luminous image; in other words, the circle of least diffusion of any pencil is a curve of sensible area, of which the central and most intense portions imprint themselves first upon the collodion.

Some further experiments were made in order to test whether the size of the circles of least diffusion was chiefly owing to chromatic aberration (in which case the difficulty might be got rid of by the use of reflectors); for this purpose a bath of solution of sulphate of copper was placed in front of a gas-burner, and the triangular diaphragm shown in Fig. A was then placed between the sulphate of copper bath and the lens of the camera; but the blue screen thus formed seemed to have very little effect in altering the breadth of the irradiation-fringe, only slightly retarding the rate of its formation; a similar result was obtained on placing a piece of yellow glass in front of the diaphragm; in this case, however, the formation of the fringe was still further retarded.

Photographers have long known that by making use of stops they can obtain a much sharper image. By way of experiment, we cut off the edges of the lens with a circular stop, and found that the inner irradiation-fringe was thus greatly decreased. It seems, therefore, fair to argue that the aberration of oblique pencils exceeds in magnitude the other disturbing causes, and that it will be well, in making preparations for the photographic observation of the transit of Venus, to avoid as much as possible all oblique pencils.

We would, therefore, place our photographic plates in the primary focus, and thus avoid the necessarily deep curves of any arrangement of lenses which may be used for enlarging the image. Whether it would be best to make use of a reflector or a refractor, remains to be settled by further experiment, but our present experiences would lead us to vote in favour of the reflector.

We cannot conclude without returning our best thanks to Mr. H. Davis, who has rendered us able assistance in carrying out the foregoing experiments.

* We are at present unable to find any explanation of the slight apparent thickening of the end of the image of the wire where it abuts upon the ruler, but the same thickening is to be found in all the plates. It may be well to remark that it appears evident from slight indication in the negatives which it would be difficult to render in a woodcut, that the true edge of the ruler coincides with the inner side of the white line (or with the side away from the image of the wire). The convexity of the end of the image of the wire cannot, therefore, be regarded as indicating even a slight chemical encroachment. The slightly tapered appearance of the other end of the image of the wire is due to the fact that the platinum incandescent wire is cooled at its points of contact with the thick copper wires of the circuit.

SCIENTIFIC SERIALS

Annalen der Chemie und Pharmacie, February and March 1872.—This double number is unusually bulky; it contains no less than 252 pages, and abounds with much interesting matter. The effect of the new management seems to be evident, as the last paper published in this number was only received on January 14; formerly some two or three months generally elapsed from the time of the reception of a paper before its publication. The number of the papers renders it impossible in the short space at our disposal to give more than a passing glance at some of the more important. Amongst them we notice three papers in continuation of Linnemann's researches; these treat of the synthesis of normal butyric acid, of butyl alcohol, and on some of the

normal butyl derivatives. The author prepared the normal butyric acid from iodide of propyl, which he obtained from the products of fermentation. This was boiled with potassic cyanide, and the product treated with alcoholic potash, yielding potassic butyrate; from this it is easy by well-known methods to prepare the alcohol and its derivatives, many of which have been carefully studied and are described in these pages.—Gorup-Besanez contributes a paper on the ozone reactions in the neighbourhood of the evaporating houses of salt springs (Gradirhäusern); he finds that when large quantities of water evaporate spontaneously or in a current of air, ammonic nitrate and ozone are formed in appreciable quantities, and that the nearer to the evaporating surface the ozone paper was placed the more intense was the ozone reaction. Schorlemmer has contributed a paper on the normal paraffines. He has examined many of them, such as pentan or amyl hydride, and hexan and heptyl hydride; he finds that by the action of chlorine on these pure bodies in each case two isomeric chlorides are obtained, and from which a primary and secondary alcohol can be produced, which yield a ketone and an acid by oxidation. The next paper is by Patera "On the means of protecting textile fabrics, &c., from fire." The author's only objection to the use of tungstate of soda, which he considers very efficient, is on account of its price. He proposes as a substitute a mixture of four parts of borax and three parts of magnesic sulphate, which is freshly prepared and dissolved in 20 to 30 parts of warm water; the fabric to be protected is dipped in the solution, wrung out and dried. A second substitute is a mixture of ammonic sulphate and gypsum. These mixtures can be used for such things as crape, tulle, muslin, canvas, wood, and rope.—Wartha has a short note on the action of potassic hydrate on anthraquinone. He finds that at high temperatures these two react and form small quantities of alizarin.—Sintenis contributes a long and interesting paper "On our knowledge of the benzyl ethers;" and Popoff another on the oxidation of the ketones, both of which deal very thoroughly with their respective subjects.

THE *American Journal of Science and Arts* for June opens with a paper on the early stages of the America Lobster (*Homarus americanus* Edw.) by Mr. S. J. Smith illustrated with a plate. Dr. J. J. Woodward contributes some Remarks on the nomenclature of Achromatic Objectives for the Compound Microscope, and Prof. A. M. Mayer a description of a new form of Lantern-Galvanometer. Mr. S. W. Ford describes some new species of Primordial Fossils, and Mr. F. B. Meek some new fossils from the Cincinnati Group of Ohio; and a further important contribution to palæontological science is found in Prof. O. C. March's paper on the Structure of the Skull and Limbs in Mosasauroid Reptiles, with descriptions of new genera and species, illustrated by four plates. The new genera described are *Lestosaurus*, four species, and *Rhinosaurus*, one species. The continued articles from preceding Nos. are Prof. Verrill on Radiata from the Coast of N. Carolina, and Prof. Norton on Molecular and Cosmical Physics.

THE *Scottish Naturalist* for July consists mainly of short notes of observations and discoveries relating to Scottish Natural History, chiefly Zoology. We find also the following articles of somewhat greater length:—Description of a new Hemipter, *Anthomyia Sonchi* (the sow-thistle fly), by Mr. Jas. Hardy; on the Nest of *Formica rufa* and its inhabitants, by Dr. Buchanan White; Notes on Scottish Hemiptera, also by the Editor; On the "Yellow Fins" of the Allan-water, by Dr. W. C. M'Intosh, and the continuation of the Lists of Scottish Lepidoptera and Coleoptera by Drs. Buchanan White and Sharp.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 20.—"On the present amount of Westerly Magnetic Declination (Variation of the Compass) on the Coasts of Great Britain, and its Annual Changes." By Staff-Captain Frederick J. Evans, R.N., F.R.S.

The rapidly accelerating value within the last few years of the westerly magnetic declination over the whole area of the United Kingdom and the adjacent seas, as observed at the fixed magnetic observatories of Greenwich, Kew, Brussels, Paris, and also at Christiana in Norway, is a subject of importance in practical navigation as affecting the compass bearings derived from charts and those laid down for the guidance of pilots.

The attention of the Hydrographic Department of the Admiralty has been constantly directed to this interesting physical fact; and as the duties of Her Majesty's surveying vessels employed on our shores between the years 1866—1870 embraced nearly the whole extent of coast line, advantage was thus taken to determine, with great attention to accuracy, the magnetic declination at widely spread and favourable localities.

The observations thus made by the surveying officers of H.M. navy are given in detail, with the corrections for secular change, to Jan. 1, 1872,* for which epoch a chart of the British Islands, exhibiting the lines of magnetic declination of equal value, is also appended. By comparing these lines with the corresponding lines given in the Declination Chart for 1842·5, Phil. Trans. for 1870, art. xiv., "Contributions to Terrestrial Magnetism," No. xii., by General Sir Edward Sabine, the annual decrease of the westerly declination, in the interval 29·5 years, over various geographical districts is thus shown:—

	′
Shetland Islands and N.E. coast of Scotland, between 56th and 60th parallels	8·24
E. coast of England, between 56th and 51st parallels	7·78
S. coast of England, between 51st and 49th parallels ... ... } Dungeness to Scilly Islands, with the Channel Islands ... ... }	7·34
(Greenwich Observatory	7·14)
Irish Channel, between 52nd and 54th parallels	7·10
Hebrides and W. coast of Scotland, between 56th and 58th parallels	6·85
Ireland, S.W., W., and N.W. coast, between 52nd and 55th parallels	6·26

It is thus seen that in the area included by the shores of the United Kingdom, the change was greater on the eastern than on the western side; as also that in the higher parallels of latitude of this area the change was greater than in the lower parallels.

By a further comparison of results as observed within the last ten to twelve years, at the same stations within the same geographical districts, the following approximate values of the present rate of annual change (westerly declination, decreasing) are obtained:—

	′
Shetland Islands and N.E. coast of Scotland...	11·2
E. coast of England (Bridlington)	10·3
S. coast of England (Plymouth)...	7·9
Scotland, W. and N.W. coasts	9·5
Ireland, S.W. coast	6·6

These values are in satisfactory accordance with those obtained in the interval (1865–71) at the following fixed magnetic observatories:—

Greenwich ...	8′·33	mean annual decrease of westerly declination.
Kew... ...	8·08	" " "
Stonyhurst ...	7·85	" " "

"On the Physical Nature of the Coagulation of the Blood," by Alfred Hutchison Smee.

"On the Detection of Organic and other Nitrogenised Matter existing in the Atmosphere," by Alfred Hutchison Smee.

"Contributions to Terrestrial Magnetism, No. XIII.," by General Sir Edward Sabine, K.C.B., V.P.R.S.

The author presents this paper as the companion of No. XI. of his "Contributions to Terrestrial Magnetism," which contained the Magnetic Survey of the Southern Hemisphere from 40° S. lat. to the extreme limit towards the Southern Pole, as does the present memoir, No. XIII. of the same series, the three magnetic elements from 40° N. lat. to the furthest attained limit of the Northern Pole. In both papers the mean epoch is the same, viz., 1842·5. Where it has been possible to do so, corrections to this mean epoch have been obtained and applied to earlier and later observations.

The determinations are derived from observers of all countries, and are arranged in zones, each of 5° of lat., passing round the globe. The table thus formed contains between 3,000 and 4,000 stations at which the magnetic elements have been determined. The observers are named, and references are made to the sources from whence their observations are taken. The paper is accompanied by maps of the resulting Isogonic, Isoclinal, and Isodynamic Lines, executed at the Hydrographic Office.

"On the Law of Extraordinary Refraction in Iceland Spar," by G. G. Stokes, Sec. R.S.

* A mean value of 19° 40′ being assumed for the westerly magnetic declination at Greenwich Observatory for this epoch.

It is now some years since I carried out, in the case of Iceland spar, the method of examination of the law of refraction which I described in my report on Double Refraction, published in the Report of the British Association for the year 1862. A prism, approximately right-angled isosceles, was cut in such a direction as to admit of scrutiny, across the two acute angles, in directions comprising respectively inclinations of 90° and 45° to the axis. The directions of the cut faces were referred by reflection to the cleavage planes, and thereby to the axis. The light observed was the bright D of a soda-flame.

The result obtained was that Huyghens's construction gives the true law of double refraction within the limits of errors of observation. The error, if any, could hardly exceed a unit in the *fourth* place of decimals of the index, or reciprocal of the wave-velocity, the velocity in air being taken as unity. This result is sufficient *absolutely to disprove* the law resulting from the theory which makes double refraction depend on a difference of inertia in different directions.

I intend to present to the Royal Society a detailed account of the observations; but, in the meantime, the publication of this preliminary notice of the result obtained may possibly be useful to those engaged in the theory of double refraction.

PARIS

Academy of Sciences, July 8.—M. Becquerel presented a memoir on the influence of pressure upon the phenomena of endosmose and exosmose.—M. E. Becquerel presented a report upon the recent memoir by MM. F. Lucas and A. Cazin on the duration of the electric spark.—M. Wurtz communicated a note by M. G. Salet on the primary spectrum of iodine.—M. H. Sainte-Claire Deville presented a note by M. L. Cailletet on the compressibility of liquids under high pressures, giving the coefficients of compressibility of various fluids at certain temperatures and pressures, and describing the apparatus by means of which these results were obtained.—M. Flammarion presented some remarks on a part of a recent note by M. de Fonvielle on some observations made during the ascents of the balloon Lea, relating especially to the halo observed round the shadow of the balloon, and accepting the explanation of M. Tissandier.—M. Becquerel presented a memoir on some effects of slow actions produced during a certain number of years. In this paper the author described certain products, having their analogues in nature, formed by slow action in a vessel hermetically closed for twenty years. They include crystals of arragonite and of rhombohedric carbonate of lime, crystals of arseniate of lime, glauberite—with potash instead of soda, crystals of carbonate of lead, and malachite.—M. T. Schlœsing presented a second note on the solution of carbonate of lime by carbonic acid, and M. Wurtz a note by M. C. Lauth in reply to a recent note by MM. Girard and De Laire on the manufacture of aniline colours. —M. Bardy also forwarded a note on the last-mentioned subject. —Analyses of a new variety of amblygonite from Montebras, of amblygonite from Hebron in Maine, and of wavellite from Montebras, by M. F. Pisani, were communicated by M. H. Sainte-Claire Deville.—M. Wurtz communicated a note by MM. C. Friedel and R. D. Silva on a third bichlorinated propylene.—M. E. J. Maumené presented a memoir on two new acids produced by the oxidation of sugar, in illustration and support of his general theory of chemical action.—M. Balard communicated a note by M. J. Riban on the aldanes, or aldehydes condensed with elimination of water, the agents employed by him for the removal of the water being sodium or zinc. For these bodies he proposes the name of aldanes. —A third part of MM. Berthelot and Longuemine's thermochemical researches upon bodies formed by double decomposition was read. The substances experimented on were protochloride, perchloride, oxychloride, and protobromide of phosphorus; and the results obtained by treating these bodies with water and with potash are here stated.—M. C. Bernard described the evolution of glycogene in the eggs of birds, in continuation of his previous communications on glycogenesis in animals.—An extract from a letter of the Abbé David to M. Milne-Edwards containing some zoological observations made in the province of Tché-Kiang, was read. The author notices a new species of *Ibis* (*I. sinensis*), a new Falcon (*F. sacroides*) a new *Elanus* (*E. sinensis*), and a new Salamander of the genus *Cynops* (*C. orientalis*). He also mentions the occurrence of some other birds, and of a great freshwater tortoise attaining a weight of 200 to 300 pounds, supposed to be *Chiria indica.*—MM. Jamin and De Laurès presented a note on the alterations of weight undergone by the human body in baths, in which they confirm the results of M. Durrien, according to which the weight of the body is maintained or increased by absorption so long as the temperature is low or moderate, but diminished by immersion in warm water.—M. Bernard presented a fifth note by M. Paul Bert on the influence exerted by changes in barometric pressure upon the phenomena of life.—MM. P. van Tieghem and G. Le Monnier presented a joint note describing the zygospores of *Mucor phycomyces*; and M. Duchartre a paper by M. Duval-Jouve on a new species of the genus *Althenia* (*A. Barrandonii*) from the south of France.—M. Milne-Edwards communicated a note by M. H. Filhol on the carnivora and chiroptera, of which the fossil remains are found in the deposits of phosphate of lime at Caylux, Fregols, and Concots. The author describes the jaw of a cat, which he names *Pseudelurus Edwardsii*; a jaw serving as a link between the cats and mustelidæ, upon which he founds a new genus, and which he names *Ælurogale intermedia*; and two jaws of dogs, described as *Canis caylucensis* and *C. Gaudryi*. At Fregols there is a breccia composed entirely of the bones of bats, which the author refers to *Rhinolophus*, under the name of *R. antiquus*.

CONTENTS

ERRATA.—Vol. vi, p. 221, col. 2, line 34 from bottom, for "Chladin," read "Chladni;" and p. 222, line 22 from top, and also in Contents, for "Allen," read "Alexander."

THURSDAY, AUGUST 1, 1872

DR. LIVINGSTONE

THE publication of two letters in the *New York Herald* from Dr. Livingstone has thrown some new light upon the discoveries on which the famous traveller has been engaged since 1867. The letters purport to have been written by the great traveller himself, but they bear unmistakeable marks of having been manipulated to suit the tastes of the readers of that very sensational newspaper. Yet, until the traveller's own journals are before the world, we must be content to gather as much information as may be picked up from this source, doubtful though it be.

These discoveries include the great mountain range separating the drainage of the Zambesi from that to the northward; a great valley receiving numerous streams, which Livingstone believes to be the true sources of the Nile; and a beautiful lake, called Liemba, which appears to form the southern extreme of Tanganyika. But the chief interest centres in the great valley commencing south of Lake Tanganyika, from which it is completely separated by intervening hills, and then turning to the north and west. It receives a vast quantity of rain, and appears to be subject to inundations. Its river, from its source in the southern mountains to Lake Bangweolo, is called the Chambese. Thence it turns due north, and flows, under the new name of Luapula, past Cazembe's town—first visited by the Portuguese—into Lake Moero. The great river then forces its way northward through the mountains of Rua, under the name of Lualaba, and spreads out into a vast lake named Ulenga, or Kamalondo, in the Manyema country. It then takes a westerly, and for a time even a southerly course, under the name of Lufira, spreading out into a lake called Lake Lincoln by the explorer; which also receives another important feeder from the mountain range to the south, called Lomame. Finally, the now mighty river turns to the north and enters an unknown land; for this was Livingstone's farthest point. But he heard that it flows into another unvisited lake, called Chowambe, and he believes it to be the Nile.

The discovery of this valley for an extent of some 700 miles, with its great river, receiving numerous affluents and flowing through four great lakes, has occupied Livingstone for the last five years. During 1867 and 1868 he crossed the mountains from the Zambesi valley, visited Cazembe, followed the river through two lakes, and traced it until it passed into the gorge of the Rua mountains. He then turned aside to the Tanganyika lake, to pick up the supplies that he expected to find at Ujiji, on its banks. His last letter was dated from Ujiji, on May 30, 1869. From Ujiji he set out to complete his work by connecting the Lualaba, where he left it in the mountains, with Baker's lake. But this expedition seems to have been a failure. He indeed crossed Lake Tanganyika again, penetrated into the Manyema country north of the Rua mountains, and traced the great river for some distance farther, and through two lakes, until he found it to be flowing due north. But here his men became mutinous, and he was obliged to return to Ujiji last year disheartened, and sorely in want of succour and fresh supplies.

That succour was at hand. Never has traveller been so keenly watched by those at home; never has assistance been forwarded with such lavish generosity. Fortunately Livingstone's old friend and fellow-traveller, during six long years of hardship and anxiety, Dr. John Kirk, had been appointed resident medical officer at Zanzibar, and he has superintended the measures for the explorer's relief with affectionate and untiring zeal. The first supplies, however, which Livingstone found at Ujiji in 1869, were sent up by Dr. Seward, Kirk's predecessor. Kirk sent up a second supply, while Livingstone was in the Manyema country, a great part of which was stolen by the men in charge. The mistaken policy of entrusting these supplies to natives was not Dr. Kirk's, but was apparently adopted under orders from the Foreign Office. A third large instalment of supplies was sent up, and Kirk zealously superintended its despatch from the mainland at Bagamoyo. It safely reached Unyanyembe, and has been of the greatest service to Livingstone. But the Geographical Society, and the people of England, were not satisfied with these measures. The great Explorer had not been heard of since May 1869, and an expedition was resolved upon to seek him out, and relieve his necessities. Liberal subscriptions, amounting to upwards of 5,000*l.*, poured in, and, as is well known, the Expedition sailed for Zanzibar under the brightest auspices last February. Thanks to the hearty and zealous co-operation of Dr. Kirk, the equipment was completed on the 27th of last April, and the members of the Expedition were on the mainland, and ready to start for the interior. Had it not been for an unforeseen intrusive element, in the shape of the Correspondent of a sensational American newspaper, all would have gone well, and the Explorer would by this time have been fully furnished forth with all necessary supplies and instruments, and with assistance which would have ensured the verification and completion of his discoveries. We cannot but feel that the members of the Expedition committed a very grave error in judgment in abandoning their work on very insufficient grounds.

It seems that the editor of the *New York Herald*, in looking about for fresh startling sensations wherewith to feed the appetites of his public, turned his attention to Livingstone and his discoveries, and despatched a correspondent to "interview" the great traveller, and so furnish new material for those large type headings and wonderful paragraphs in which that well-known paper delights to indulge. So far no harm had been done, except that a *New York Herald* "Correspondent" was the very worst messenger that could have been selected. For it was to his interest to keep all he had done, all Livingstone had told him, a close secret until a wondrous version of it could appear in New York. Carefully concealing his object while at Zanzibar, the correspondent advanced into the interior, found Dr. Kirk's ample supplies waiting at Unyanyembe, and after some difficulties caused by his own mismanagement, reached Ujiji, where he found Dr. Livingstone. There is some mention of Mr. Stanley, the correspondent,

having accompanied Livingstone on an excursion to the northern end of Lake Tanganyika; but this statement has not yet been corroborated by the great traveller himself. Livingstone then proceeded to Unyanyembe, which is about a third of the way from Lake Tanganyika to the coast, where he found the supplies sent up to him by his old fellow-traveller, Kirk. Here he awaits further supplies, before setting out on a fresh expedition of discovery: while the correspondent set out for the coast, after having "interviewed" the great traveller to his perfect satisfaction, and having obtained material for a whole series of sensational articles.
